SEC. 6. When an action is commenced to recover the cost and expenses for draining a lode or mine, it shall be lawful for the plaintiff to apply to the court, if in session, or to the judge thereof in vacation for an order to inspect and examine the lodes or mines claimed to have been drained by the plaintiff, or some one, for him, shall make affidavit that such inspection or examination is necessary for a proper preparation for trial. The court or judge shall grant an order for the underground inspection and examination of the lodes or mines described in the petition. Such order shall designate the number of persons, not exceeding three, besides the plaintiff or his representative, to examine and inspect such lodes and mines and take the measurement thereof, relating the amount of water drained from the lode or mine, or the number of fathoms of ground mined or worked out of the lode or mine claimed to have been drained, the cost of such examination and inspection to be borne by the party applying therefor. The court or judge shall have power to cause the removal of any rock, debris or other obstacles in any lode or vein, when such removal is shown to be necessary to a just termination of the question involved; provided, that no such order for inspection and examination shall be made, except in open court or at chambers, upon notice of application for such order of at least three days, and not then except by agreement of parties, nor unless it appears that the plaintiff has refused the privilege of making the inspection and examination by the defendant, his or their agent.

SEC. 7. That hereafter, when any person or persons, or corporations, shall be engaged in mining or milling, and in the prosecution of such business shall hoist or raise water from mines or natural channels, and the same shall flow away from the premises of such persons or corporations, to any natural channel, gulch or draw, the same shall be considered beyond the control of the party so hoisting or raising the same, and may be taken and used by other parties the same as that of natural water courses.

SEC. 8. After any such water shall have been so raised, and the same shall have flown into

any such natural channel, gulch or draw, the party so hoisting or raising the same shall only be liable for injury caused thereby in the same manner as riparian owners along natural water courses.

SEC. 9. The provisions of this act shall not be construed to apply to undeveloped mines, but to those only which shall have been opened, and shall clearly derive a benefit from being drained.

SEC. 10. In trial of cases arising under this act, the Court shall admit evidence of the normal stand or position of the water while at rest in an idle mine, also the observed prevalence of a common water level or a standing water line in the same or separate lodes; also the effect (if any) of elevating or depressing the water in the same, contiguous or separate lodes or mines; also the effect of draining or ceasing to drain any given lode or mine had upon the water in the same, contiguous or separate lodes or mines, and all other evidence which tends to prove the common ingress of subterranean communication of water in the same lode or mine, or contiguous or separate lodes or mines.

Gould & Curry Water.

We were yesterday, says the *Virginia Enterprise*, shown an analysis of the water struck by the diamond drill on the 1700-foot level of the Gould & Curry some time ago. The analysis was made by John Hewston of the Pacific refinery. In a gallon of 221 cubic inches there was found of indissoluble sediment, of fine sand and micaceous earth, 33.24 grains. Total of soluble salts, 30.279 grains, consisting as follows:

	Grains.
Sodium.....	0.04
Silica.....	2.21
Sulphate of lime.....	14.35
Sulphate of Soda.....	6.42
Alkaline carbonates.....	7.26
Magnesia.....	None.
Iron.....	None.

For the purpose of comparison we republish an analysis of the Hale & Norcross water, made some time since and published in the *Enterprise* Feb. 8th. In a gallon of 231 cubic inches there was found:

	Grains.
Chloride of sodium.....	1.327
Silica.....	3.500
Sulphate of lime.....	22.532
Sulphate of soda.....	8.342
Sulphate of potash.....	18.513
Magnesia.....	Trace.
Iron.....	None.
Total.....	54.216

STANDARDS OF WEIGHT AND MEASURE.—Professor Hennessy, in a paper on "New Standards of Measure and Weight," says that, owing to the objections many persons will entertain to the metric system, he brought forward for consideration the standards which he had prepared several years since and which had been subsequently advocated by Sir John Herschel. The standard of measure was a bronze prismatic scale, which was the fifty-millionth part of the earth's polar axis. From that a system of weights was derived by taking a fraction of the standard of length as the side of a cube and finding the weight of an equal volume of distilled water. In that way a series of weights was constructed in bronze. A chain containing 50 links, each equal to the bronze standard, was also constructed, and that chain was, therefore, the millionth part of the earth's polar axis. The link, or standard scale measured very nearly 10.0007 English inches, and its tenth part, therefore, was very little in excess of an inch. That, as well as the geometrical superiority of the axial standard over one derived from a meridian, seemed to have influenced Sir John Herschel and others in preferring it to the meter. Geometrical measurements had, in fact, shown that the earth was a somewhat irregular spheroid; and, therefore, that its meridians were equal, while the polar axis was necessarily unique and corresponded to every meridian. On these grounds Professor Hennessy thought that the new standard might be universally accepted by all nations, if the objections to the meter would prevent its universal adoption.

EVERY new subscriber who does not receive the paper and every old subscriber not credited on the label within two weeks after paying for this paper, should write personally to the publishers without delay, to secure proper credit. This is necessary to protect us against the acts and mistakes of others.

WE carry the N. Y. watch, and you can refer to the publishers of this paper as to the superiority of the N. Y. Watch Company's movements, manufactured at Springfield, Mass. Also to any one else who owns one.

Don't trifle with a poor watch when you can buy a good one of Dewey & Jordan, 433 Montgomery street, San Francisco, at prices according to the times.

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

NEW AND SECOND-HAND.

One Patent Straw-Burning, Portable En-
 gine, (new,) fire box boiler, the best
 Portable Engine on the coast; built
 by Ransom, Sims & Head, Ipswich,
 England.
 One Steam Fire Engine, second-hand,
 in excellent condition, with 200 feet
 leather hose, very cheap, just the thing
 for a small town. Button & Blake,
 builders, Waterford, N. Y.
 One second-hand Stationary Engine, 14x30
 inches, link motion, with or without
 hoist gear.
 One second-hand Stationary Engine, 8x20
 inch, with or without hoist gear.
 One Upright Boiler, Horizontal Engine
 on wheels, Eastern make, 7x12.
 One Upright Boiler, Horizontal Engine,
 San Francisco make, 6x12.
 One small Stationary Engine, 3½x7 inch.
 One Steam Boiler, 40 inches diameter, 16
 feet long.
 One 8x10 Straw-Burning Portable Engine.
 One Stationary Engine, 8x16, and Boiler,
 with pump heater, fire front and smoke-
 stack, complete.
 One Traction Engine, three wheels, rub-
 ber tires, double cylinder, 6x10 inch;
 Thompson's patent, D. D. Williamson,
 builder, New Jersey.
 Various other second-hand Engines and
 Boilers for sale cheap.

Buy the Best.

Before purchasing an American
 Watch, examine the different styles
 manufactured by the NEW YORK
 WATCH COMPANY, at Springfield,
 Mass. They are the latest and
 best improved manufacture. You
 can depend upon them for fine finish,
 durability and perfect time. They
 are sold at favorable prices—in
 fact, no higher than many of the
 inferior styles. Examine into the
 merits of this Watch before you
 buy any other. Our word for it,
 you will not regret it.

 at 433 Montgomery street, S. F.,
 for 13 years. They are reliable—like the "New York watch-
 es" they sell.

ARITHMETIC MADE EASY.

ROPP'S

EASY CALCULATOR

Is a new publication that must prove of incalculable
 benefit to Farmers, Mechanics and Business Men. It is
 so rapid and original as to startle the most scholarly,
 and yet so simple and practical that the most illiterate
 in figures can instantaneously become his own account-
 ant. It enables thousands to accomplish in a minute
 what they could not learn to calculate in many months.
 The first part contains an entirely new system of tables,
 which show at a glance the exact value of all kinds of
 Grain, Stock, Hay, Coal, Lumber, Merchandise, etc.,
 from one pound up to a car load, and for any price that
 the market is likely to reach; the interest on any sum for
 any time at 6, 7, 8 and 10 per cent.; correct measurement
 of all kinds of Lumber, Saw Logs, Cisterns, Tanks, Gran-
 aries, Bins, Wagon Beds, Corn Cribbs; a Time, Wages
 and many other valuable tables.

The second part is a practical arithmetic, and embodies
 a simple mechanical principle which enables any one
 familiar with the fundamental rules to become a light-
 ning calculator; and by which over two-thirds of the fig-
 ures and labor required by the ordinary methods, and
 fractions with their intricacies, are entirely avoided.

The work is nicely printed on fine tinted paper, is well
 and elegantly bound in pocket-book shape and is accom-
 panied by a Silicate Slate, Memorandum and Pocket for
 papers. It is by far the most complete, comprehensive
 and convenient pocket manual ever published.

Price, bound in Fine English Cloth, \$1.00.

Send direct from the Eastern publisher, postpaid, on
 receipt of price, by P. O. order, registered letter, or
 receipted by express. Address

 forated Sheet Metals of every
 description. I would call special
 attention to my SLOT CUT and
 SLOT PUNCHED SCREENS,
 which are attracting much at-
 tention and giving universal
 satisfaction. This is the only
 establishment on the coast de-
 voted exclusively to the manufac-
 ture of Screens. Mill owners using Battery Sore, a exten-
 sively can contract for large supplies at favorable rates.
 Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

Continued from page 245.

ELY DISTRICT.

RAYMOND & ELY.—Pioche Record, April 14: The Raymond & Ely mill is now running steadily on tailings, ten stamps being employed on ore. It is doing good work, as the bullion shipments will show. Good ore is being taken from the mine but there has been no change in the general working.

BULLION FROM HIGHLAND.—The small furnace at Highland has started again, the result being that 48 bars were brought to Rooder's store from it on Thursday and 53 bars yesterday. It works well and there is every prospect of a continuation.

HAVE QUIZ.—The chlorides in the Raymond & Ely mine quit work on Saturday, the 31st inst., the time in which they were allowed to chloride having expired. Most of them having been busily engaged shipping their ore by the N. C. R. R. to the Colorado mill in the past week.

BULLION COMING IN.—Eleven bars of bullion were delivered at Wells, Fargo & Co's office on Wednesday last from the Raymond & Ely mill, it being brought to Pioche by the N. C. R. R. This is pretty good work for a nine days run and commences to make things look like old times.

RICIN.—Some very rich ore was struck in the Raymond & Ely mine during the past week on the fifth level, the pulp assay going over three hundred dollars.

EUREKA DISTRICT.

FURNACE SITE.—Eureka Sentinel, April 13: The Hamburg company owns a fine property in the canyon north of town, including water rights, furnace sites and several buildings. It is the intention of the company to erect two furnaces on the hillside, directly opposite the old Roslin furnace, a plateau that exists at that point. A ditch is brought along the hillside directly to the spot, and an ample water supply is found in several springs, controlled by the company, further up the canyon. A good grade can be easily constructed from the Secret canyon road; and taken all in all, there is no place in the vicinity that was better adapted for the site for the furnaces.

THE ROSLIN FURNACE.—The old Roslin shaft furnace stands like a monument up the canyon, and its form and construction is about all the evidence that we have left of the early smelting operations in this camp. As compared with one of our huge furnaces of the present day, its proportions are very small, and smelters smile at the crude work done when it was erected. It has not been in operation for five years, and the building and machinery surrounding it have been torn down and removed.

WHITE PINE DISTRICT.

THE EBERHARDT AND AURORA MINE.—White Pine News April 14: Work is being pushed on the incline below the 1000-ft station, with no material change in the general formation of the ore. We learn that several new drifts are being run for prospecting purposes, with very favorable indications. But the main energies of the management are directed to carrying the incline down as fast as possible, so as to connect with the tunnel.

THE TUNNEL.—The Eberhardt and Aurora tunnel has passed its 1000-ft, and is going ahead finely. The air-flume, which was completed to give proper ventilation, works like a charm, and no further inconvenience is likely to be experienced for a long time on account of impure air. The machinery and everything connected with the tunnel, work well, and no stoppages or delays occur.

Arizona.

BIG BUG DISTRICT.—Arizona Miner, April 13: This old, favorite district is looking up. One mine, owned by Gen. Kautz, has been patented, five others, owned by merchants of Prescott, are now being patented. Several rich discoveries of both gold and silver have recently been made. Messrs. Roberts and Poland are actually quarrying out of the Mesa lode, situated some two miles above the Isabella mill, one that glitters with gold, and which, for want of milling facilities, they are reducing in horse arastras. It is a fact, not generally known, that there has been more mines developed and more bullion extracted from this district than from any other district in Yavapai county, except the Peck. The old Big Bug mill, erected by Mr. Hitchcock in 1868, ran on ore two years, and under Mr. Hitchcock's management for six months, that he ran the mill, in 1869-70, made a net profit of nearly \$3,000 per month. With the roads all made, and the facilities for timber and water, few places offer better inducements for the safe investment of capital.

LYNX CREEK.—Messrs. Elliott & Rice, owners of the Accidental mine, have just struck a bonanza in the tunnel 125 feet below their former rich strike. Few, even in Prescott, are aware of the extent of the development of the mine. The lower tunnel is in 575 feet and work is pushed night and day. The ore is hauled about one mile and a half and is reduced by means of a crusher and four arastras, run by steam power. The last run yielded \$21 per ton.

BLACK CANYON.—The Humburg mining district, near Black canyon, is attracting a good deal of attention, and there is being extracted and shipped tons of very rich ore. Five different lots of from three to five tons are now lying at the Aztlan mill, several other lots on the road, and if the miners could get their ores worked or sell them on the ground hundreds of tons would be taken out. A first-class silver mill erected in the district would pay the owners immense profits, and would soon build up a lively camp.

THE AGUA FRIA SMELTER is blowing away, day and night, Sunday included, and boiling out the precious metal, in combination with some that is not quite so precious, by the tons.

Colorado.

NEW DISCOVERIES.—Colorado Miner, April 7: Jack Baker, one of the original discoverers of the Baker mine in Argentina, has recently found a big vein at the mouth of Spring or Golconda gulch, about a mile below Mill City. Where the gulch has cut the vein, a discovery has been made on each side, and a tunnel started on the vein each way. On the west side, he has gone 18 feet, revealing a vein of mineral three feet wide. On the east, he has gone 15 feet. Further east another discovery has been made; it is a very strong vein of bluish ore, rich in copper and galena wherever uncovered.

YOUNG AMERICA LODE.—The eastern end of this lode, on Red Elephant mountain, is being worked at a point a little east of the discovery shaft, by Messrs. Rodgers and Bradley, who are taking out pay. The ore is very rich in silver, assaying over 1,000 ozs. and always averaging well at the mill. It carries a good deal of copper, and is also rich in lead.

THE ANGLO-SAXON.—The Anglo-Saxon is now being worked on two levels—one at a depth of 280 feet below the surface at the discovery, and the other at a depth of 100 feet below that, making 380 feet in all.

THE BISMARCK LODE is situated on the southwest slope of Sherman mountain. The vein has been opened for a distance of 2,500 feet—called on the west the Cataract, and on the east the St. Jo. Mr. E. Y. Naylor has obtained a patent of 1,500 feet on the St. Jo, and proposes to work it the coming season. The ore is worth \$400 per ton net at the mill.

THE CROSS LODE.—Col. Harney and Chris. King have commenced work on the Cross lode on the west side of Leavenworth mountain. The ore found in the Cross is generally rich. A mill-run made last week by parties now working on the east end of the Cross, gave a result of 900 ozs. first-class, and over 200 ozs. for second-class.

ANOTHER MILL STARTED.—The Kansas and Colorado mining and milling company have leased the old Lincoln company's mill at Mill City, and are preparing to run a fine arastras on ore from the Alchinson and Falmouth lodes, on Trail run. They propose to run the surface quartz and ship the ore, which is rich in copper. A trial of the surface quartz has already been made, which panned out \$40 in fine gold.

GREAT GOLD STRIKE.—Lewis lode, at Empire, about 400 feet above the Cambridge, is a new discovery by Gulbar & Harrington. The prospects in the pan are wonderful. Eight pans of dirt from the crevice gave \$31 in gold, or nearly \$4 to the pan. Ten pounds of the quartz pulver-

ized, gave 7 dwts, 6 grains of gold, or about 65 cents per pound. The width of the pay vein, at a depth of 1 1/2 feet, is 16 inches, and about 2,500 pounds of this rich quartz and dirt have been taken out of the shaft in going to that depth.

Idaho.

GOLDEN CHARIOT.—Owyhee Avalanche, April 14: Recent operations in the Golden Chariot have resulted in the most cheering developments. A rich and promising ledge has been encountered, which shows up splendidly in gold, and is of such dimensions and complexion as to justify the most enthusiastic hopes of all interested relative to the future of the Chariot. The new ore body bears all the characteristics of a first-class bonanza, and we can assure the owners of this magnificent property that all the indications are most promising, and that their investments here are certain to be rewarded by returns that will surpass their most sanguine expectations. The Golden Chariot mill will commence crushing next week. There are several hundred tons of rock from the Potosi, Lepley and other mines here, so that it may be a month or more before the mill commences on Chariot rock.

NORTHERN LIGHT.—Some 38 tons of rock from the Northern Light mine, near town, were crushed a few days ago, and the crushing averaged nearly \$200 to the ton. This yields a net profit to Mr. Douglass, the owner of this mine (after deducting the expenses incident to the extraction of this rock, milling, hauling and assaying), of \$5,000 and upwards, quite a snug little sum, considering that the time consumed in taking out the ore was only about six weeks. The value of the bullion was about \$7,230.

POORMAN.—Great hopes are entertained respecting the Poorman. All the old miners and prospectors of this vicinity are firm in the belief that there is more solid wealth in that mine than there is in any other on the Pacific coast.

The following mine is looming up splendidly. Mr. Cary and his associates, who have been working it for the past few months, are jubilant over the prospect. They have got a magnificent ledge, with abundance of rich ore.

The Belle Peck and Potosi mines are both looking first-rate and will soon be giving a good account of themselves in the shape of bullion yield. These mines will be actively worked during the season.

The Hidden Treasure ledge is being worked by a limited force, and the rock is being taken out through the Empire shaft. There are 12 tons ready for crushing.

From South Mountain and Wagontown we have nothing new. Prospects do not seem to be very bright for a lively season in either of those camps.

Utah.

NEW SMELTERS.—Cor. Salt Lake Tribune, April 12: Enterprises of great moment are now being entered into in San Francisco district. Messrs. Wm. Godde and Shearman & St. Luke, have made satisfactory arrangements with the owners of the Horn Silver mine, and will immediately commence the erection of extensive smelting works at the town of Frisco. The Horn Silver mine is developed to an extent that I can safely say it is the largest deposit of smelting ore in Utah. There is considerable excitement in this district over the finding of a second horn silver mine, two miles north, in the same range. Those who have visited it and are reliable, say it is all that it is represented. The lucky discoverers are new comers to the camp. On the west side of the San Francisco range of mountains can also be found a busy camp, and it is there that some very fine veins of iron ore are found, and worked to supply the smelters with flux. Copper also abounds to a considerable extent, and some very good bodies of high grade galena.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco.

CALIFORNIA FRUIT AND MEAT SHIPPING CO.—April 13th. Object: To deal in meat, fruit, fish, produce of every character and general merchandise, and to do a business of a transportation, forwarding and commission merchants. Directors—John Cashin, Wm. Johnston, Charles Grove, J. Earl, J. D. Blanchard, W. S. Bailey, B. B. Norton, Wm. Tothunter and J. McCusick. Capital stock, \$50,000.

SOUTHERN DEPOT LAND CO.—April 13th. Object: The buying and selling of real estate. Directors—Charles Crocker, Leland Stanford, David D. Colton, Mark Hopkins and Thomas B. Lewis. Capital stock, \$340,000.

WESTERN REFRIGERATOR CAR CO.—April 16th. Object: The operation of refrigerator cars and transportation of meats, vegetables and fruits. Capital stock, \$1,000,000. Directors—James H. Spotts, Charles M. Keeney, Bernard Lande, Albert T. Spotts and Robert Williamson.

PACIFIC CARRARA MARBLE CO.—April 16th. Capital stock, \$3,000,000. Object: Developing veins of marble and dealing in the same. Directors—Gustavus S. Ashmead, Edward T. Menomy, James Atkinson, Wm. M. Wainsley and George A. Hill.

Meetings and Elections.

CALIFORNIA STOCK EXCHANGE.—April 14th.—J. L. Armstrong, President; W. F. Hughes, Vice-President; John Gray, Chairman; E. M. Lawton, Secretary, and G. H. Brundage, M. Morgenstein and J. J. Tobin, Executive Committee.

NEW ENGLAND SHELTING AND TUNNEL CO.—Trustees: Chas. Moss, C. H. Baker, J. D. Fry, J. Ballard and W. H. Hart.

IRON WORK FOR CITY HALL.—Sealed proposals for material and work at the City Hall were opened by the City Hall Commissioners on Tuesday. The bids for iron work were as follows: Iron staircases and steps and other iron work, to be completed in 22 weeks: Lewis & Co., \$26,937; Nutting & Son, \$27,290; Savage & Son, \$28,450; J. M. Stockman, \$36,197; Jonathan Kittridge, \$27,184; Stieger & Kerr, \$34,900; Rankin & Co., \$39,745; Low & Charters, \$35,975. Wm. T. Coleman, corrugated iron arching with lathing, where the girth is less than eight feet, 4 1/2 cents per superficial foot; without iron lathing, where girth is eight feet and over, 47 cents per superficial foot; iron lathing, where used in combination with iron arching, 30 cents per superficial foot; iron bracketing and lathing for cornices, 53 1/2 cents per foot; iron lathing on wood of partition, 20 cents per foot; on wood furring of walls, 20 cents per foot; ironing, furring and lathing in partition, 30 cents per foot; fixed diagonally, 40 cents.

The Germania mine has been sold to parties in New York for \$45,000, of which \$10,000 has been paid, and the remainder will be paid August 1st.

ABOUT 1,000 northern hostile Indians made a formal surrender of their arms, ponies, etc., to General Crook this week at Spotted Tail agency, Neb.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

PATENTS AND INVENTIONS.**A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.**

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

FOR WEEK ENDING APRIL 10TH, 1877.

189,354. TRACTION HORSE-POWER.—D. T. Gillis, San Leandro, Cal.
189,472. FRUIT-DRIER.—J. M. Keeler, S. F.
189,477. PIPE COUPLING.—S. Lightburn, Jr., S. F.

4,527. TEAS.—A. Mann & Co., S. F.
1,030. THE STOCK CONDITION POWDER.—Painter & Calvert, S. F.

—The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

BUTTON-HOLE ATTACHMENT TO SEWING MACHINES.—Eugene Moreau, S. F. This invention relates to an improved clamp for gripping the cloth around the borders of button-hole openings in the cloth plates of button-hole sewing machines, so as to hold the cloth immovably in place while the button-hole is being worked. Heretofore these cloth clamps have been made either in the form of a single clamping plate, which entirely surrounded the button-hole opening; or in two parts or halves, one part or half serving to clamp the cloth on each side of the opening. Cloth and finished work, however, when ready for the button-holes, is often unequal in thickness at different points along the border of the button-hole, because most frequently the button-hole must be made through two and even more thicknesses of cloth. The difficulty experienced has been that although a solid clamp is pressed firmly on the cloth around the button-hole opening or upon each side as above stated, there will be still places where the pressure is not sufficient because of the unequal thickness of the material so that the needle of the machine will cause the edge to draw and thus mar the finish and uniformity of the button-hole work. The invention under consideration consists in constructing a clamp with two or more narrow independent presser feet, placed side by side, each of which will exert an independent downward pressure upon that portion of the cloth directly under it, and thus provide a continuous clamp which will adjust itself to the inequalities of the cloth, and thus insure its immovability.

HORSE-POWER.—D. T. Gillis, San Leandro, Alameda county. This invention is to provide an economical and effective means for working pumps by horse-power, and it consists in a running gear and pivoted bearing, in combination with a walking beam and rods arranged to operate a pump movement. The axle of the running gear is arranged to be propelled around a fixed center by horse-power, with a traction wheel and weight for insuring the necessary friction and rotation of said wheel, the other end of the axle is a crank rod of a pump movement. When it is desired to employ a horse to pump, he is hitched to the running gear by means of a pole and driven around in a circle, the rotation of the traction wheel and axle imparting to the pump movement the requisite stroke for pumping purposes through the medium of the crank joint, walking beam and vertical rods.

FRUIT DRIER.—Jas. M. Keeler. This is an improvement upon the American Fruit Drier, which adapts it for making raisins from grapes, and also renders it more convenient and useful as an ordinary fruit drier. We have described this machine previously, and will probably present an illustration of it shortly.

FLUXES.—Chas. F. Secor. This patent covers improvements in a combination of native fluxes for smelting "dry ores." Mr. Secor has been using these fluxes for a long time and has brought them to perfection for work on a large scale.

SILK WORM EGGS EXPORTATION.—Japan now exports silk worm eggs, principally by way of San Francisco. The route by India has been abandoned. The railroad across the American continent enables Japanese exporters to prolong the season and send off boxes down to the end of the year, which would be impossible by way of Suez. The Messageries' maritime steamers thus lose an important freight.

LEAD has advanced in Liverpool to £21 2s 6d to £21 7s 6d for good ordinary brands.

ANTIMONY has advanced in England to £51 to £53 per ton for French star regulus.

QUICKSILVER is worth £7 5s to £7 10s per flask in Liverpool.

General News Items.

The Chico incendiaries are now on trial.

The Grand Duke Alexis is in Washington.

The confession of Boss Tweed has occasioned a great flurry among New York politicians.

FIRST LIEUTENANT E. G. GRENOUGH has been detailed as Professor of Military Science and Tactics at the University of California.

HON. JOHN F. KASSON, of Iowa, has been tendered and has accepted the position of United States Minister to Spain.

OCCIDENT beat Oakland Maid on the Bay District track, on Saturday, in a match to wagon for a purse of \$2,000. Time, 2:25, 2:27 1/2, 2:27 1/2, 2:29 1/2. The Maid won the third heat.

In a day or two 200 employees of the Bureau of Engraving and Printing of the Treasury Department will be dismissed. This reduction will be followed at the end of the month by the additional dismissal of 200 more.

The West Point graduating class this year numbers 77, the largest ever graduated. There are only 40 vacancies in the army, consequently 37 will be appointed Brevet Second Lieutenants under the law, and promoted to the grade of Second Lieutenants as vacancies occur.

A DECISION has been rendered in favor of Myra Clark Gaines, in the famous Gaines suit, involving millions of dollars worth of property in New Orleans. The litigation has extended over 40 years, and this decision ends the struggle in favor of the claimant.

For sons of parents residing in this city, no charge is made for the maintenance of boys on the Jamestown training ship. For country boys, however, a charge of \$15 per month is made, payable six months in advance. The fit-out for each boy costs about \$30, and is furnished by the ship commander.

THE TRIBUNE says: The recent mails brought instructions from Australia and Cape Colony to houses in England to make up consignments of hardware from American and not from British products. Merchants in those distant countries are captivated with the beauty and low prices of our hardware goods.

Academy of Sciences.

The regular meeting of the California Academy of Sciences was held on Monday evening last.

The following specimens were received by donations to the cabinet: Graphite, 12 miles from Sonora, Cal., by Dr. J. B. Trask; 36 specimens of minerals from Dr. E. S. Holden, of Stockton; shells from the Colorado desert, by J. P. Moore; eight specimens of Indian skulls and other crania, from Stockton, by R. K. Reed, M. D.

Some specimens of white and of brown paper were exhibited, manufactured at Lick's mill, in Santa Clara county, from the fiber of the yucca, a plant of the Colorado desert. From five tons of the material three and a half tons of the paper were produced.

Dr. Stout presented, on behalf of Mr. Alvord, some fish eggs, from Los Angeles. The eggs are similar to those of the dog fish, in having an envelope or life preserver, but differing in regard to shape. The envelope of the dog-fish eggs is shaped like a flat-bottomed boat. The eggs presented have an envelope whirled like a wheel or helix.

Prof. Davidson read a paper on "Mechanical Defects in Micrometers," having reference to certain irregularities or errors observed as resulting from friction in the movements of the micrometer screw in procuring distances and diameters, and suggesting methods of construction calculated to determine satisfactorily the arc value of each turn of the screw. We shall publish the paper in full.

Prof. Davidson stated that, at the next meeting of the Academy, he would present some original papers on the breakwaters at Alexandria, Brest, and in England.

A SUPERIOR WATCH.—Americans may well be proud of our ingenious inventors and "artistic mechanics." They beat the world, as the present triumph of American watches testifies unerringly. The New York Watch Company, at Springfield, Mass., started but a few years since with the latest and best inventions, improved tools and select and skilled workmen. When we say now that their watches are not surpassed, and are seldom equaled for perfect finish and fine time-keeping qualities, we know that we are speaking of an article which will bear the scrutiny and closest tests of experts. Dewey & Jordan, agents, at 433 Montgomery street, S. F., have just prepared to meet purchasers on this coast with timely prices for these superior watches. Send for their price list.

SCIENTIFIC PRESS.—As the old year is drawing to a close and the new is rapidly approaching, all our mining friends should subscribe for this scientific journal, especially devoted to their interests. It is a California enterprise, and compares favorably with similar organs of years more experience and age in the old countries.—Colfax Enterprise.

"SPRINKS WELL," Etc.—We would return thanks for an exchange and list of names of the MINING AND SCIENTIFIC PRESS, published by Dewey & Co., of San Francisco, Cal. It is a well edited, interesting, and valuable journal and speaks well for our Pacific neighbors.—U. S. Mining and Manufacturing Journal.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. THAYER—San Francisco.

H. W. CROWELL—Columbia, Butte, Sutter and Yuba counties.

G. W. MCGREW—Santa Clara county.

A. C. KNOX—Nevada, Montana and Utah Territories.

C. N. WEAVER—Santa Cruz, Monterey and San Benito counties.

A. C. CHAMBERLAIN—Sonoma and Marin counties.

A. U. STROM—Lake, Napa and Solano counties.

W. D. WHITE—San Bernardino and Los Angeles counties.

E. G. GAERTNER—Arizona Territory.

ED. T. PLANK—Dakota Territory (Black Hills.)

THE GRAND PACIFIC HOTEL, Chicago, with its central position and railroads branching off in every direction, is naturally a point to which travellers from all parts of the country are apt to come more or less frequently. Being there, a hotel is a necessity. A first-class one in every respect will be found in the "Grand Pacific," which is the temporary home for our off-hand Western folks who want to go to the best place the first time. The hotel is a handsome one and is fitted up in fine style with all the modern conveniences. It is centrally located, keeps a first-class table with the best market affords at all times and seasons, and the proprietors know how to make their guests feel at home.

WHEN so many poor watches are being sold, it is not too much for us to say that those who buy the New York Watch Company's movements will be sure of a good article at fair prices.

THANKS—OFFERING.—REV. S. S. HARMON, President of Washington College, an interested observer of agricultural progress, writes: "I have just been looking over the RURAL PRESS. I am most favorably impressed with its contents. Its range of agricultural matter is wide and deeply interesting. One such number as the last is worth the price of the whole volume. It is a great, good work in which you are engaged, your audience is very large and should become larger every day. I do not know that truisms of this kind are of any value to you, but I write them as a sort of thank-offering for what I deem to be a very valuable service you are rendering to the State."

To Ship and Engine Builders, Steamship Companies, Etc.

A Mechanical Engineer, having an extensive experience in Marine Engineering (especially compound) and Iron Ship Building, also in Steam Engines and Machinery in general, is open for engagement. First-class references.

Address and references can be obtained at office of SCIENTIFIC PRESS.

Mining and Assaying Offices,

504 WASHINGTON STREET, S. F.

Instructions on Analysis and Assaying. By Fire, Blow-Pipe and Chemicals.

By Fire, Blow-Pipe and Chemicals.

Explorers', Miners' and Metallurgists' Companion, 672 pages, 83 illustrations. Second Edition. Price, \$10 50. The Prospector's Patented "Wee Pet" Assayer. The Testing Machine for Gold, Silver, Lead, &c.

Price of "Wee Pet," \$100. The Tester, \$40.

CHARGES FOR ASSAYING, &c. Assay for Gold and Silver, Copper, Iron, Lead, or Antimony, \$3. All other Metals, \$5 each. Minerals tested at 1/4 per Metal. Qualitative or Quantitative Analysis of Ores, \$10 or \$25; Coals, \$10 or \$50; Water, \$25 or \$75; and of Manures or Soils, \$25 or \$50.

BENTLEY MARCANDANT & CO
MANUFACTURERS OF SUPERIOR
UNIVERSAL WOOD WORKERS
BAND SAWS, SCROLL SAWS
PLANING & MATCHING MACHINES
UNIVERSAL JOINTERS
MOLDING, DOVE-TAILING, BORING, FRIEZING, SHAPING &c.
SAND PAPERING MACHINES, PLANER KNIVES & MOLDING BITS.

GRASS VALLEY, NEVADA CO., CAL.

Amusements.

GRAND OPERA HOUSE, Mission Street, near Third. Open every evening with first-class Dramatic Company. Box office open from 9 A. M. to 10 P. M. Doors open at half past seven. Commence at eight o'clock.

CALIFORNIA THEATER, Bush Street, above Kearny. Open every evening with the best Dramatic Company in the United States. Box office open from 9 A. M. to 10 P. M. Seats may be secured six days in advance. Doors open at half past seven.

W. T. GARRATT'S
BRASS and BELL FOUNDRY
SAN FRANCISCO.

MANUFACTURER AND IMPORTER OF
Church and Steamboat BELLS and GONGS,
BRASS CASTINGS of all kinds,
WATER GATES, GAS GATES,
FIRE HYDRANTS,
DOCK HYDRANTS,
GARDEN HYDRANTS
A General Assortment of Engineers' Findings.

Hooker's Patent
Celebrated
STEAM PUMP
The Best and Most Durable in use. Also, a variety of other PUMPS
For Mining and Farming Purposes.

ROOT'S BLAST BLOWERS,
For Ventilating Mines and for Smelting Works.
HYDRAULIC PIPES AND NOZZLES,
For Mining Purposes.
Garratt's Improved Journal Metal.
IMPORTER OF
IRON PIPE AND MALLEABLE IRON FITTINGS
ALL KINDS OF
WORK AND COMPOSITION NAILS,
AT LOWEST RATES.

N. W. SPAULDING'S

PATENT DETACHABLE TOOTH SAWS.
Manufactory, 17 & 19 Fremont St., S. F.

R. HOSKIN,
Duch Flat, California.
MACHINES and PIPE
For Hydraulic Mining.
Special attention to manufacturing pipe where it is to be used.

The Latest and Greatest Improvement in Hydraulic Mining Machinery is Hoskin's Deflector, Pat. Dec. 12, 76

The DEFLECTOR DOES NOT SPRAY THE STREAM. ADMITS OF THE NOZZLES BEING CHANGED, OR MAY BE USED WITHOUT A NOZZLE.

IMPROVED VERTICAL ENGINE.

Any parties needing STEAM ENGINES, from Four to Ten Horse-Power, will do well to call on me before purchasing elsewhere. Particular attention is called to my improved Feed Pump.

W. H. OHMEN,
Practical Engineer and Machinist.
32 Fremont Street, San Francisco, Cal.

ERICH G. GAERTNER,
MINING ENGINEER.

All classes of mining properties reported on, consultations had on reduction of ores of all descriptions, plans for furnaces and reduction works furnished, and the construction of them superintended. Ore tests made at the office.

309 California Street, Rooms 8 and 9.

Dewey & Co. { 224 Sansome St. } Patent Agt's.

To Mining Secretaries.

An amendment to Section 336 of the California Code, taking effect July 1st, 1874, provides that in addition to the regular publication, daily or weekly, of the assessment and sale notices as heretofore,

PERSONAL NOTICE

Must be served as provided in the following quotation from the law:

"The notice must be personally served upon each stockholder, or in lieu of personal service, must be sent through the mail, addressed to each stockholder at his place of residence, if known, and if not known, at the place where the principal office of the Corporation is situated."

The above refers to the ASSESSMENT NOTICE only. Advertisers in the MINING AND SCIENTIFIC PRESS will be furnished with copies of assessment notices printed on slips suitable for serving personal notice under this law at short notice.

DEWEY & CO., Publishers.

Mining and Other Companies.

California and Arizona Mining Company.
Location of principal place of business, 507 Montgomery Street, San Francisco, California. Location of works, Mohave County, Territory of Arizona.
Notice is hereby given, that at a meeting of the Board of Directors, held on the third day of April, 1877, an assessment (No. 2) of two cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin to the Secretary, at the office of the company, 507 Montgomery Street, San Francisco, Cal.
Any stock upon which this assessment shall remain unpaid, on the thirteenth day of May, 1877, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the fourth day of June, 1877, to pay the delinquent assessment, together with the costs of advertising and expenses of sale. By order of the Board of Directors.
T. E. JEWELL, Secretary.
Office, 507 Montgomery Street, San Francisco, California.

California Fruit Growing Association.
Location of principal place of business, San Francisco, California. Location of property, El Dorado county, Cal.
Notice is hereby given that at a meeting of the Board of Directors, held on the 14th day of April, 1877, an assessment, No. 4, of \$2.00 per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary at the office of the company, 331 Sansome Street, San Francisco, Cal.
Any stock upon which this assessment shall remain unpaid on the 4th day of May, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before will be sold on Saturday the 9th day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expense of sale. By order of the Board of Directors.
HORACE JONES, Secretary.
Office, 331 Sansome Street, San Francisco, Cal.

Dolores Consolidated Mining Company.
Location of principal place of business, San Francisco, California. Location of works, Dolores Mining District, Esmeralda County, Nevada.
Notice.—There are delinquent upon the following described stock, on account of assessment (No. 1) levied on the seventeenth day of February, 1877, the several amounts set opposite the names of the respective shareholders, as follows:

Name.	No. Certificate.	No. Shares.	Amount.
Blasdel, H. G., Trustee.	16	10,000	\$1,000 00
Blasdel, H. G., Trustee.	17	5,000	500 00
Blasdel, H. G., Trustee.	18	5,000	500 00
Blasdel, H. G., Trustee.	19	5,000	500 00
Drexler, L. P. & Co., Trustee.	8	25,000	2,500 00
Fry, J. D., Trustee.	7	10,000	1,000 00
Keene, J. R., Trustee.	9	10,000	1,000 00
Tate, W. C.	10	3,100	310 00

And in accordance with law and an order of the Board of Directors, made on the seventeenth day of February, 1877, so many shares of each parcel of such stock as may be necessary, will be sold at public auction at the office of said company, on Monday, the sixteenth day of April, 1877, at the hour of two o'clock, P. M. of said day, to pay said delinquent assessments thereon, together with costs of advertising and expenses of the sale.

J. W. CLARK, Secretary.
Office, 418 California street, San Francisco, California.

POSTPONEMENT.—The sale of the above described certificates of stock is postponed from the 16th day of April, 1877, to the 16th day of May, 1877, and will then take place at the same hour and place as above named. By order of the Board of Directors. J. W. CLARK, Secretary.

Klamath Quartz Mining Company.
Notice is hereby given that the principal place of business of this company will be removed to Klamath Mill, Siskiyou County, California, from the City and County of San Francisco, California, in thirty days from the date of the first publication of this notice.
GEORGE H. FOREE, Secretary.
San Francisco, March 21, 1877.

Mariposa Land and Mining Company of California.—Location of principal place of business, San Francisco, California. Location of works, Mariposa County, Cal.
Notice is hereby given, that at a meeting of the Board of Directors, held on the 28th day of March, 1877, an assessment (No. 10) of one dollar per share was levied upon the capital stock of the corporation, payable immediately in United States currency, to the Secretary, at the office of the company, Room 33, Nevada Block, No. 309 Montgomery Street, San Francisco, California, or to the Assistant Secretary, at the office, No. 8 Nassau Street, New York.
Any stock upon which the assessment shall remain unpaid on the Thirtieth day of April, 1877, will be delinquent, and advertised for sale at public auction; and unless payment is made before will be sold on Monday the Twenty-eighth day of May, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.
LEANDER LEAVITT, Secretary.
Office, Room 33, Nevada Block, No. 309 Montgomery St., San Francisco, California.

Taylor Mill and Mining Company.—Principal place of business, City and County of San Francisco, State of California. Location of works, Garden Valley Mining District, El Dorado County, California.
Notice is hereby given, that at a meeting of the Board of Directors, held on the twenty-ninth day of March, 1877, an assessment of Twenty Cents per share was levied upon the capital stock of the company, payable immediately in United States gold and silver coin, to the Secretary at his office, No. 607 Montgomery Street, in the City and County of San Francisco.
Any stock upon which this assessment shall remain unpaid on the ninth day of May, 1877, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Friday, the twenty-fifth day of May, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale.
SAMUEL S. MEEFEY, Secretary.
Office, No. 607 Montgomery Street, San Francisco, Cal.

The Ingersoll Rock Drill

Is Extensively Used in the East and

TAKES THE PLACE OF ALL OTHERS,

Wherever introduced, because it can be run with less power, labor and repairs, and do more work than any other Drill in the market. It has but few parts, is easily handled, being light, and has AUTOMATIC FEED, which saves labor. WE ASK FOR TRIAL AGAINST ANY COMPETITOR. For particular information regarding Drills or Air Compressors, send for circular to

J. B. REYNOLDS,

(Room 10.) 320 Sansome Street

THE O'HARRA CHLORIDIZING FURNACE

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this Process:

Two cords of wood at \$6.....\$12.00
Two firemen at \$4.....8.00
1,500 lbs. of salt at 1c.....22.50
Wear of shoes and power.....1.50

Cost for 15 tons.....\$44.00
Cost for one ton.....2.85

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in the Peavine District. For further information, apply to

D. J. O'HARRA,
Reno, Nevada.

CAST STEEL SHOES
AND DIES.

Guaranteed Cheaper than the Best Iron.
IMPORTANT NOTICE.
Reduction in Price from 16 Cents
to 12 Cents Per Pound.

Owing to our largely increased business, the present low price of iron from which our Steel is manufactured, and the improved facilities for casting and forging, we take great pleasure in announcing that from and after this date we will supply our IMPROVED CAST AND FORGED STEEL SHOES AND DIES FOR QUARTZ MILLS at twelve cents per pound, delivered at San Francisco or Sacramento, instead of sixteen cents, as heretofore.

We also furnish Steel Plates for Blake and other Ore Crushers, Steel Out Gearing, etc., for Mills and Hoisting Works, Steel Pan Shoes, Battery Cams and Tappets, etc., etc.

Address all orders, with dimensions or drawings, to

CAST STEEL SHOE & DIE CO.,

59 Nevada Block, S. F.

TULLOCH'S AUTOMATIC ORE FEEDER,

Awarded the Centennial Medal.

The TULLOCH AUTOMATIC ORE FEEDERS have been practically tested during the last year and a half in 40 mills, of from five to 30 stamps each, and have, in every case, given perfect satisfaction. The Tulloch machine is so constructed that the drop of the stamp feeds the ore in just such quantities as the stamps require. Each drop regulates the supply required for the next drop, whether it be more or less, and this is the true principle of an automatic feeder. The tray moves longitudinally, and a stationary scraper forces the material forward at each backward movement of the tray, thus insuring the perfect feeding of all classes of ore, whether it be dry or wet.

We append a few extracts from the many testimonials which we have received from mill men and practical mining men, of the effectiveness and positive action of the Tulloch Feeder. We do not depend solely upon these testimonials, as we are aware that testimonials are easily secured for almost any machine, but the high character of the parties certifying to those herewith given, will establish their value and genuineness:

Mr. Jas. G. Fair has 28 in use; says: I regard them superior to any Feeder with which I am acquainted; I consider no mill perfect without them. Mr. E. R. Burke, Sumner mine, Kern county, has 16; They never get tired; no man living can feed a battery as well; they save us in labor alone \$48 a day. Mr. Green, of the Phoenix mill (12), Amador, writes: The first machine we had is working away; is as good as ever; have not spent a dime on it; in use 14 months; you need fear no competition on wet ores. Mr. W. H. Armstrong, of Consolidated Virginia mill: We are running 60 stamps with your Feeders; they give unbounded satisfaction; they have not cost the company one dollar since starting up. Mr. H. C. Bidwell, Supt. Green Mountain and Gold Strike companies, Plumas county, writes: From the start they have done splendidly; no trouble whatever; requiring but little attention; a boy can manage them; the saving in both labor and castings is fully one-half over the old style of feeding by hand. Mr. Preston writes: I have four of your Automatic Self Feeders, and my mill men each and all say they are the best they have ever used. They are an improvement on all I have ever seen, being simple in construction, and good for either wet or dry crushing; refer to over 40 mills using them; they are guaranteed to give perfect satisfaction. Send for circulars.

F. OGDEN, 22 California Street, S. F.

PICKERING ENGINE GOVERNOR.

VALLEJO FOUNDRY, October 17th, 1876.

Messrs. NEYLAN & YOUNG, San Francisco,

Agents for "PICKERING GOVERNORS."

Gentl:—The 10 two-inch Improved Speed Adjusting Governors I bought of you this year for my patent Straw Burning Threshing Engines give splendid satisfaction. They far surpass for regularity of speed any Governor that I have ever seen, and I have seen all the best kinds; I have seen the main belt fly off the pulley several times this season while threshing, and the engineer did not discover it, so perfectly was the speed maintained, until he was told of it; this I consider something wonderful; I consider the Governor absolutely perfect, so far as speed is concerned. I bought and put on to one of my engines a Shive Governor, to see which was the best, and after one season's trial I have no hesitation in saying they are far superior to any other Governor that I have seen or used. I wish you would send me the lowest price that you can furnish 25 Governors for next season's engines. Yours respectfully, J. L. HEALD.

The only Governor that has received awards at each of the International Exhibitions. American Institute Fair, New York, 1865, Two Medals; Mechanics' Institute Fair, Baltimore, 1865, Silver Medal; American Institute Fair, New York, 1869, Two Medals; International Exposition, Paris, 1867, One Bronze and Two Special Medals; International Exposition, Vienna, 1873, Medal of Progress and Decoration; International Exhibition, Philadelphia, 1876, Medal and Diploma.

ASBESTOS COATING,

FOR STEAM BOILERS, PIPES, ETC.

THE BEST NON-CONDUCTOR IN USE,

"SALAMANDER FELTING."

Our Patents Especially Embrace the use of ASBESTOS, LIME and PAPER-PULP for Boiler Covering.

The Material is applied (in a plastic form), in three coats, each one-half inch in thickness.

The "first coat," which protects the outer coatings from the severe heat of the surface covered, is composed principally of ASBESTOS and lime-putty, and is strictly fire-proof and indestructible.

The "second" and "finishing" coats are composed largely of the "paper-pulp," which in combination with other light non-conductors of heat, forms a material that will never crumble or crack off, and which is susceptible of a fine enamel-like finish.

Send for circulars containing testimonials from well known authorities in the East, and on this Slope.

Each Barrel of Salamander Felting sold by us will bear our Trade Mark and the dates of our several Patents.

DATES OF PATENTS:

September 14th, 1869, October 5th, 1869, October 4th, 1870, May 9th, 1871.

WARNING TO INFRINGERS:

The U. S. and Foreign Salamander Felting Co.

Hereby notifies, cautions, and warns the public—and particularly engineers and proprietors of Steam Machinery—that their patents for "ASBESTOS BOILER COVERING," having been fully sustained by Repeated Decisions in the U. S. Courts, all infringers will be duly prosecuted.

Some of the more important of the above mentioned decisions were against the "ASBESTOS FELTING COMPANY, of New York," and parties USING THEIR MATERIAL. Pamphlets containing full accounts of these and other cases will be furnished on application. It must be remembered that those using an infringement are as liable to prosecution as those manufacturing and vending it.

All parties on this Coast, having used the

"ASBESTOS FELTING." (of New York,) and MERRELL'S SO-CALLED "STEATITE FELTING,"

(Which analysis shows to infringe in nearly every case), or any other infringing material, are hereby notified that they will in time be called upon for ROYALTY and DAMAGES; but are at the same time CAUTIONED against paying such royalty or damage to any but the authorized agents of the

SALAMANDER SMELTING COMPANY.

Ours are the Only Patents for Boiler Covering that have ever been established by the Courts.

WE WILL PAY THE HIGHEST PRICE FOR A GOOD QUALITY OF ASBESTOS.

Mechanical Ore Concentration and Separation—No 23.

[Written for the Press by FRANCIS M. F. CAZIN, M. E.,
Santa Fe, New Mexico.]

[In a former chapter of this series Mr. Cazin sent us a description of the Blake ore crusher, to appear in that part relating to ore crushers and breakers. As, however, the cuts did not come to hand, the description was deferred until a convenient place in the article was reached. As there is only one more chapter before the conclusive remarks, it is thought proper to insert the description of the Blake crusher in this place.—Eds. Press.]

The Blake ore crusher and stone breaker, illustrations of which are shown on this page, are extensively used in this country as well as in Europe. Various sizes of the crusher are made to suit different requirements. Numbers four, five and six are generally used for mining purposes.

In the sectional view, A is the main frame; B, fly wheels; C, driving pulley; D, crank shaft; E, pitman; G, G, toggles; H, fixed jaw; I, cheek; J, movable jaw; K, rubber spring; N, wedge; O, toggle block; P P, jaw plates; and W, wedge nuts.

It will be seen that the distance between the jaws at the bottom limits the size of the fragments. This distance, and consequently the size of the fragments, may be regulated at pleasure. A variation to the extent of five-eighths of an inch may be made by turning the screw-nut, W, which raises or lowers the wedge N, and moves the toggle block, O, backward and forward. Further variations may be made by substituting for the toggles, G G, or either of them, others that are longer or shorter; extra toggles of different lengths being furnished for the purpose.

The face plates of the jaws are made of chilled iron. When worn at the lower end after long use, they can be inverted and thus present a new surface to the action of the ore, or can be replaced by new plates at small expense.

The engravings show the new pattern of crusher, large numbers of which are in use. The operation is seen at a glance. The amount of power required of course depends on the size and the work; and the amount of product depends on the distance the jaws are set apart, and the speed. As regards proper sizing for certain material, reference is made to previous chapters of this series. These crushers are made by the Blake Crusher Company, New Haven, Conn.

PROGRESS FOR YOUNG AMERICA.—In all the large Eastern cities we find amateur printing presses displayed in numerous store windows for sale. Six years ago we observed nothing of the kind. This shows progress. California is not to remain long behind. Mr. H. F. Rockey, at No. 22 Kearny street, has opened a fine assortment of presses and "all sorts of sorts" for our young folks to lay their hands on, at reasonable prices. Akin to this subject an exchange truthfully remarks: "As a source of instruction and amusement, the printing press stands pre-eminent. Parents, guardians and teachers can do no wiser a thing than to place in the hands of their children a small press and a few founts of plain type. There is a fascination and pleasing variety in printing that never ends, and in which old, as well as young, find mental advantage. We feel that we are engaged in a good work, in advocating the introduction of the press into schools and families, as a means of education and enjoyment."

A MASS meeting of the people of the Black hills was held in Deadwood City, Saturday. A memorial to Congress was adopted urging the formation of a new Territory, embracing the Black hills region, to be called Lincoln. A resolution was adopted accrediting Hon. J. B. Chaffee, Senator from Colorado, as a representative to urge this claim in the United States Senate.

The Mining Review, of Denver, is to be consolidated with the Engineering and Mining Journal, of New York City, the consolidated paper to be published in New York, with the Western office in Denver.

Jumping Claims.

Nothing could be more absurd than the idea that some persons seem to have concerning the United States mining laws as far as they relate to the relocation of claims. The manner in which claims may be relocated is so plainly set down in the law that it seems as if one could scarcely go wrong; and by strict compliance with the law the relocater will be protected by the courts.

When, however, miners deliberately "jump" and take possession of a man's mill, hoisting works and other outside improvements, as well

work it. For this reason, the government has a right to prescribe conditions under which the ground shall be worked; but as it never had any title to the mills or hoisting works and they were not bought or used under any agreed conditions, the government has nothing whatever to do with them, and has no more right to give them away because they are not worked than it has to do any other unjust thing. If they exceed this authority over quartz mills it would be equally fair for the same authority to be exercised over other things of like character.

It seems almost amusing that people will continue to go on the principle that when the claim is forfeited the mill and other works in the mine are forfeited also. Scarcely a week passes that we do not hear of instances of this

PERSPECTIVE VIEW OF NEW PATTERN BLAKE CRUSHER.

as a claim, they show a want of common sense as well as ignorance of the laws. They have no more right to take up a mill than they have to take a man's house and furniture, because the mining claims on which they are are forfeited by non-compliance with the laws regarding annual expenditures. Because a mill lies idle for a year without any expense being put on it, that is no reason why any one coming along

kind. The latest case is that one in Placer county where some parties who jumped the old Montana mine near Colfax, also jumped the quartz mill with the impression that the law gave them the right to do so. On thinking the matter over a little any one can see that no claim could be justly put on the mill, and there is no doubt whatever that the original owners can take possession when they choose, and perhaps prevent the parties taking the mill prop-

SECTION OF NEW PATTERN BLAKE CRUSHER.

should take possession and acquire title to it any more than a man could go and take possession and use at will a dwelling house that had not been used by its owner or rented for a period of time. The United States government has no more to do with giving away a man's mill or hoisting works than anything else he may have and what he did not acquire from the government in the first place.

Mining ground is a different thing altogether. The minerals belong to the government, and the laws virtually give a man the right to mine ground under certain restrictions as long as he likes, and he may reap all the profit he can; but in failing to comply with the regulations presented by the bona-fide miner—the government—he must give it up to some one who will

erty, especially if it is disturbed in the slightest degree.

BULLION SHIPMENTS.—Since our last issue shipments of bullion from prominent mines have been as follows: Modoc, April 17th, \$4,987.53; Northern Belle, 17th, \$7,530.16; Comanche, 17th, \$11,354.53; Indian Queen, 15th, \$5,828.86; Northern Belle, 19th, \$8,620.74; California, 21st, \$157,193.03—total to date, \$1,000,068.27; Con. Virginia, 21st, \$144,409.79—total to date, \$366,929.11; Tybo Con., 18th, \$15,664—total to date, \$56,832.05; Modoc, 21st, \$5,514.09—total to date, \$60,688.40; Arizona, 22d, \$2,118; Grand Prize, 21st, \$4,876; Northern Belle, 22d, \$10,552.89; Chollar, 24th, \$15,513.52; Tybo Con., 22d, \$12,133.97; total to date, \$69,166.02.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

WATER CLOSET.—Fred. R. Pohley, S. F. This comprises certain improvements on a closet patented by the same inventor, Oct. 31st, 1876. In that patent is shown a valve closing against the end of the pipe and retained in place by springs, which act upon it so as to resist a certain amount of pressure, and when the water within the pipe has accumulated to a certain extent its weight will overcome the tension of the springs and thus allow the surplus to escape. This device is susceptible of being applied to water closets in its present form, but in order to make it practical and entirely successful, Mr. Pohley has invented an improved construction which is especially adapted to water closets, and in this patent he has shown a peculiar adaptation and arrangement of the valve, which is placed at an angle so that all of the contents of the bowl will be allowed to escape without any danger of clogging and preventing the closing of the valve. The valve is supported upon a single stem, so guided as to move at an angle with the face of the valve-seat, and thus carry the valve to one side of the discharge passage, and entirely out of the way, and the closing spring surrounds or acts upon this stem or valve. The stem is constructed with a suitable lever which opens the valve, and, at the same time, admits a flow of water to cleanse the bowl; and a trap of peculiar construction is formed to receive any overflow and prevent any return of odor.

WATER FILTER.—Wm. S. Snook, Oakland. The object of this invention is to provide a cheap filter for attachment to water pipes through which water is conducted under pressure, so that the water can be purified and cleansed for drinking and other purposes. By the means employed the inventor is able to use an open-top tank as a filtering vessel. Inside the tank and a short distance above its bottom is secured a horizontal perforated partition upon which is placed the usual filtering substance. Above the filtering material is placed another partition so that it can be cleaned when desired. The water is brought into the tank under pressure by means of a pipe which leads under the partition and the water then rises up through the filtering material and is cleansed in its passage. A waste pipe is arranged so that when it is desired to clean the filter the water may be turned in above the filtering substances, and the impurities will be carried off through the waste pipe. This filter can be cheaply constructed and easily managed so that it is of great value for household purposes.

WASHING CALENDER.—Mrs. H. E. Israel, Stockton. This is a novel device, called a "Washing Calender," which consists of a circular convex form made with columns of figures radiating from a centre to the circumference, where, at the head of each column is placed the name of some article of wearing apparel. The numbers in each column run as high as may be desired, and pins are employed to mark the numbers of each article sent to the laundry; while around the circumference a space is left in which to place the total amount.

The mines of Pyramid district are looking well and the miners are much encouraged. The Reno Journal says that work is being prosecuted on nearly all of the claims—so much so that there is not an idle man there. In fact it is frequently hard to find a man to go to work when extra force is needed. As the mines become more developed the ledges look better and better. The entire district offers the most flattering prospects, and this summer will see many important strikes made.

The Vulture gold mining company filed a petition in bankruptcy in the United States District Court on last Saturday, with liabilities of \$88,105.17.

CORRESPONDENCE.

Mining in Elko County, Nevada.

[From Our Traveling Correspondent.]

At no very great distance north of Elko and other points on the line of the railroad, many new districts have been discovered during the past five years. In most of them good prospects have been found. In many of them work is at present being prosecuted with more or less vigor and success. In none, even of the most advanced, has any great depth been attained.

If, however, a judgment can be formed from the surface indications, a very prosperous future may be predicted for the county.

In addition to Cornucopia and Tuscarora, the two principal districts visited (and of which, in view of the magnitude and importance of their operations, a notice more in detail is required), in almost every direction, as far as developments have gone, good strong veins are reported, and in many instances represented as carrying ore of high grade, so that the prospects of this part of the State were probably never brighter.

Rock District

Is 60 miles north of Elko and 10 miles from Tuscarora. It was discovered in July last. The most usual country rocks are porphyry and quartzite.

The Falcon, the discovery claim, under the superintendence of Mr. R. D. Norton, and which may be taken as a sample of the district, is incased in the porphyry. The ledge can be traced for a mile by the croppings. Several other locations have been made, such as the Scorpion, Lookout, Challenge, Aspin, the Hunter and Flagstaff. The quartz on the croppings is from six to 10 feet in width, and at the depth of 45 feet on the Falcon, the pay ore is full three feet, giving assays in antimonial and ruby silver from \$300, the lowest, as high as \$2,400.

Favorable mention is made of Lone Mount, Cape, Hicks, Bull Run, Wyoming, Kit Carson, Boulder, Junction, Delano and a few other districts, but

Tuscarora

Is at present taking the lead; a new and rising star, fast becoming the great center of attraction in northeastern Nevada. The lodes are numbered by the hundreds and the locations are literally "legion." The general formation is porphyritic, accompanied with syenite, gneiss, talc and other rocks, bordered on the north by the granite. In close proximity, if not in contact with it, lies the Grand Deposit ledge, bounded on the south by the ever-present porphyry. Running parallel with this, in an easterly and westerly direction, the general formation is cut by a belt of talcose slate, on or near which the Grand Prize is located, at this time the leading mine of the district. Besides the afore-mentioned east and west veins, there are probably others.

Of north and south veins there are said to be 100 or more, covering an area of about four square miles from east to west, running parallel and nearly at right angles to the granite formation. The Young America, the De Frees and other promising mines are located on these, at no great distance from the cross ledge of the talcose slate belt already mentioned.

So much by way of introductory. Something of the kind seemed almost essential for a proper understanding of the localities of the different claims to be described. The order mapped out will be followed as far as possible, beginning with the claims on the east and west belt in the northern part of the district belonging to

The Grand Central M. Co.,

A San Francisco incorporation, embracing the Grand Deposit, previously referred to, and the Star lode. Their ground is situated from 1,000 to 1,200 feet north of the De Frees and on the same hill, and about the same distance from the talcose belt, on which the Grand Prize, Moscow and some other locations are made. It is believed that the company have a good, strong contact vein, the Grand Deposit, struck by an 80-foot shaft, being represented from five to six feet in width, carrying rich sulphuret ore. The assays are reported as running all the way from \$30 to \$3,000 per ton, silver. It is understood that work will soon be resumed under the management of Mr. S. Linkton, Superintendent of

The Grand Prize.

This mine is said to have been discovered and located, in June last, by Mr. J. Woods, of Tuscarora, associating with him Messrs. Hanam and Crane as locators. A shaft of 50 feet was sunk, laying bare such a fine body of horn-silver ore that it soon passed into the hands of one of your capitalists and afterwards duly incorporated. The 10-stamp mill of the Windsor company was forthwith purchased for working the ore, and operations renewed in earnest on the mine. It is thought to be a true fissure vein; formation, porphyry; direction, east by west; dip north 70°, and varying from three to ten feet in width. Main vertical shaft, of 220 feet, has three compartments. Main drift on the 150-foot level is 550 feet in length. Bullion to the amount of \$80,000 was turned out at the mill during the month of March, the ore paying

\$200 per ton. The total, yielded since operations commenced last fall, will reach \$125,000 and upwards. The outlook for the company is looked upon as exceedingly flattering. On the authority of the *Tuscarora Times*, "a contract has been entered into between the company and Messrs. White & Allen, of San Francisco, for the construction of a 20-stamp mill, the same to possess all the latest improvements, with 12 pans and full complement of settlers."

It is understood that the first east extension of the Grand Prize shows a similar ore at the depth of 120 feet; assays from \$65 to \$160.

First West Extension,

Owned by Messrs. Bobier, French and others, has a shaft of 120 feet on one side of the lode. A cross-cut had been made at the 60-foot level, showing a two and a half-foot vein. Assays of ore at this point ranged from \$15, the lowest, to \$358. Another cross-cut at the 120-foot level had just reached the vein when visited, showing good ore at that depth. Expectation runs high in regard to this claim, as well as to the other locations on the same vein.

The Moscow

(Muncey & Co.), lying further west on the talcose slate belt, and thought to be on the same lode as the Grand Prize, the ore possessing the same characteristics (horn silver predominating), is from 10 to 12 feet between walls, with at least eight feet of ore. It gives average sample assays of \$166 per ton, some choice pieces running in gold and silver as high as \$2,200.

The Lida,

Adjoining on the west, and owned by the same company, is nine feet in width, with four feet of similar ore.

Having given what is thought a fair specimen in brief of the east and west belt,

The De Frees Mine,

Located on a north and south lode, 1,158 feet southwest of the hoisting works of the Grand Prize, will now be taken up. Capt. Wm. Williams, a well known mining engineer, an old acquaintance, was found in charge, from whom the following facts were soon gathered: The lode has an average width of two feet, although at one point widening to six feet; direction north 53° west, dip 45° west. The wall is a porphyritic syenite, of a yellowish cast. The ore gives high assays in both gold and silver.

Without going into the details of the workings, it is sufficient to state that the adit tunnel has been driven in the aggregate on the course of the vein 255 feet, and that the total of drifts on the 73-foot level amounts to 350 feet. In addition to the ore body laid open by the developments, there are 600 tons of good milling ore on the dump, besides many more hundreds of tons that could be made to pay well by careful assorting. The company in connection with the property have also a small stamp mill, eight miles distant, with ample water power for 30 stamps.

Southwest of the De Frees 1,730 feet is the hoisting works of

The Young America,

The first location and discovery claim on a parallel ledge. Incline shaft 230 feet. Drifts north and south from shaft on one level, aggregating 380 feet, and on the 60-foot level as much as 600 feet—extending 65 feet into the ground of the Young America south, making a total drift along the vein of 665 feet, disclosing the fact of its continuance the entire distance, and a width varying from one to five feet. There are large bodies of good ore exposed to view by the developments, and some 600 tons on the dump, estimated to work from \$50 to \$125 per ton in silver and gold.

The shaft, 6x6, has been handsomely retimbered and work will soon be resumed. The average width of Young America, as shown by incline of 90 feet on vein, is 20 inches. Average sample assays from one portion of vein is reported at \$280. A shaft of 60 feet on the Young America north shows an average vein of 30 inches, and sample pulp assays from 20 tons extracted, of \$110 per ton.

On the next belt west of the Young America are the claims of

The Tuscarora Consolidated M. Co.,

Mr. T. S. Brown, Superintendent. They embrace the Warsaw, Susan Jane, the Occidental and May-be-so. The Warsaw at present worked has a shaft of 45 feet in depth, and a vein from 16 inches to two feet—the foot-wall syenitic gneiss, and the hanging a species of quartzite. In sinking shaft 25 tons have been taken out. The ore will probably mill \$75 per ton or more—principally gold. The other veins have been opened to some extent, the ore giving assays from \$30 to \$150.

The Revenue, adjoining on the south, is 18 inches in width at 25 feet, and will average \$25 per ton.

The Navajo.

Owned by Beard and Lancaster Bros., further west, averages two and one-half feet in width and contains very high grade ore near the surface. A few tons on the dump were estimated to work at the rate of \$400; average sample assays of ore from another portion of the claim having run as high as \$787 per ton.

The Diana, the first north on the same lode, owned by Messrs. Edwards, File and Truett, is well defined and four and one-half feet wide. Assays of ore on surface, \$80. The Hornet following next in the same direction, the property of Messrs. Berry, Hamilton and Raines, is reported as shipping ore last fall that worked from \$200 to \$250.

The Ophir, lying south of the Navajo on the

same ledge (shaft 45 feet, drift 35), furnishes ore assaying from \$85 to \$165. It runs about \$30 in gold.

The Robert Emmett.

(Pitz, Walsh & Co.), lies west of the Navajo and Hornet and is from 6 to 15 feet in thickness. It is incased between the porphyritic and syenitic gneiss and opened by shaft 60 feet, the ore growing more compact and vein better defined as the work advances.

There are two different and distinct strata of ore, the one largely predominating is gold and the other in silver. It is thought, with proper assorting, the ore can be made to mill from \$150 to \$200 per ton. Further south on this range the Venture, North Venture and Paymaster are opened by shafts from 40 to 50 feet deep, and are all looking well. The Venture is represented as having a three-inch seam in the vein that is unusually rich in gold, an assay going as high as \$22,000.

The Wild Cat, on the same vein, together with the Baltic, El Capitan, the Alcemany and others on the next hill west, may be mentioned as promising for the developments, giving good fair assays in gold.

The Windsor mining company have a three-foot vein of ore, represented to run high in gold. The mine has not been worked for some time, but it is thought here that it will not long lie idle.

The Mamie Norton,

Situated three miles west of Tuscarora, the property of Messrs. Black & Hampson, has a direction east of north, a few points, as most of the veins last described, shaft 60 feet, drift from 15 to 20 feet, eight feet from wall to wall; syenite forms the foot and faldzite the hanging wall. Some assays have run in the neighborhood of \$1,500, the larger proportion silver, while some of the ore, worked for the gold alone, averaged \$130 per ton.

The tale forming a portion of the gangue near the surface, changes more to quartz at the 60-foot level. There are many other locations as worthy of mention as some that have received attention, but this will suffice.

A careful review of the facts here presented will lead to the conclusion that one of the great wants of the district is

A Good Twenty-Stamp Custom Mill.

The impression generally prevails that a sufficient amount of rich ore can be taken out near the surface to make it a paying property. If so, it would at once give a fresh impetus to every department of business, labor for many idle hands, the ready means to the miner from his ores for sinking or for machinery, and at the same time opening up a wide and profitable field of employment for a large class here who are so well satisfied as to the richness and abundance of the ores as to be willing to take their chances as "chloriders." A like state of things, not perhaps of the same extent, in some places, seems to exist in many parts of eastern Nevada, where the work of development has evidently been greatly retarded for want of cheap facilities at hand for getting quick returns from their ores.

Notes from Cornucopia not yet fully written up, hope to have them in shape by next issue.

A. C. K.

The Sutro Tunnel.

We recently, says the *Virginia Enterprise*, received a private letter from San Francisco, asking if the mining companies intended using the Sutro tunnel after it reached the Comstock, and, if so, when it would be done. Not being able to answer the question authoritatively, we give the following general view of the situation and leave it for all who are interested to answer it for themselves. We simply wish it distinctly understood that what follows is written in the confidence of neither the mines nor of Mr. Sutro.

The Sutro tunnel is gradually working its way up toward the 1750-foot level of the Savage. Its progress during the month of February was very rapid, over 100 feet being sometimes made in a single week. The work of pushing along the header has been progressing more slowly of late, on account of the nature of the formations encountered, which are heavy and slippery, requiring the protection of the cut by timbers. This will be the case, doubtless, at intervals, all along the route yet to be run, since the header is now in the great ore-belt of the Comstock lode. In the Comstock mines, where drifts are usually about 4 by 6 feet in the clear, the pressure is frequently so great as to crush 12 by 12 timbers as though they were pipe-stems. The header of the tunnel is 8 by 10 feet, and consequently still greater care must be exercised to prevent caves. This, of itself, will necessitate the employment of men constantly to ease the timbers after they are put in and thus prevent their being broken down, and will, in a measure, hinder the rapid progress of the tunnel toward the present workings of the mines. The tunnel will not, as is generally supposed, strike our deep workings 2,000 feet below the surface, but near the present 1750-foot level of the Savage, or 2,000 feet below the Gould and Curry croppings.

On the 1st of the month, the date of the last measurement, the header was reported to be in 16,433 feet. This must bring it within 1,000 feet or so of shaft No. 4. The course of the tunnel carries it 364 feet north of the great Chollar-Norcross-Savage shaft, which is located on the eastern side of the ravine and far to the east of all the great workings of the Comstock.

That shaft is now being driven down below the 1,200 foot level at the rate of from 2 to 3½ feet per day. Under the old rate of tunnel speed the parallel of this shaft should have been reached about October 1st, and the Comstock January 1, 1878. At present this shaft is encountering very little water, and that is readily handled by the skeets without incurring the expense of pumping. By the time, however, that it reaches the tunnel-level very likely more water will be encountered. To be sure, the combination shaft is supplied with one of the most powerful pumping engines on the whole lode, but sufficient work will thereafter be found for that, since the company intend to go, if necessary, from 1,000 to 1,500 feet below the tunnel level in order to strike and prospect the lode.

Those who entertain the idea that this great combination shaft has been located and is being sunk to cut off Mr. Sutro from the Comstock, have, it seems to us, but a very superficial idea of the true nature of this immense mining undertaking. When it is considered that the dip of the Comstock is to the east, and that work through inclines is always prosecuted at a disadvantage, and with a loss of power besides that expended on the increase of distance; and above all, that depth is the great requisite now to success, the wisdom of going nearly a mile to the east, of sinking a perpendicular shaft, which shall at once overcome all these obstacles and gain the more readily the desired end, is apparent. We believe the accomplishment of this purpose to be the object in projecting this shaft and in pushing it on down.

By the time the tunnel reaches the line of this shaft two things may, therefore be counted upon. Mr. Sutro will want air, and the shaft companies will have water to spare. What can be more natural than that a connection should be made through the 364 feet intervening between the two, thus supplying Mr. Sutro with what air he wants, and allowing the water of the shaft companies to run down and out the tunnel. The advantage would be mutual. To be sure each could continue his allotted work independent of the other, but since the connection would result to the advantage of both, reason and common sense alike would look to the general good and make the connection.

Let us now look a little further. Should the Chollar-Potosi mining company prosecute work from their present shaft to any great extent below the 1750-foot level, they will, in all probability, be required to purchase new and heavy hoisting and pumping machinery. The same is true of the Hale and Norcross, except that they have the requisite pumping apparatus. The Savage company have both the hoisting and pumping machinery, but by using Mr. Sutro's tunnel the expense of running both would be greatly lessened and work could be more readily pushed to a greater depth. This is also true of both the other companies mentioned. And, since all these companies must prosecute in the future the work of development below their present level, what more natural conclusion can be arrived at than that the tunnel should be used as a drain for the mines, if for no other purpose.

Reasoning thus, solely on the grounds of economy and availability, the probabilities are that the tunnel of Mr. Sutro will be utilized even before it reaches the present mining operations on the Comstock, and most naturally after it gets here. It would add materially to the developments of to-day could it be made available to carry off the great head of water which is giving so much trouble in the Savage and Hale and Norcross. Even if it only allowed the water to be discharged at the 1750-foot level of these mines, a higher point than it has ever reached, it would loosen energies and motive powers, which could then be immediately concentrated and made available below that level.

In the foregoing we have confined our speculations to the case of three mines only, deeming those sufficient to answer the question asked in a general way.

ARIZONA MINES.—We are pleased to record that the mining outlook improves daily. Mining men from abroad are beginning to turn their eyes towards Arizona as the coming mining country—the new Washoe. They are beginning to find out what we have known all along—that the mines of Arizona are the equal of any in the world. It is true that our mines are, as yet, in their early infancy; but from the northern part of our Territory to the extreme south are mining districts which bid fair to become, in richness and extent, formidable rivals to those of Nevada. For years, the hardy pioneers of this once wild land have braved the dangers of a frontier life, and have done their "assessment work" with the pick in one hand and the trusty rifle in the other, not knowing what moment the latter might be called into requisition to save them from death by the hand of the hostile savage. Now, the country is pacified, and mining men who are sick of gambling stocks, and looking for a field in which they can invest in legitimate mining enterprises come every day to find what we have to show in the way of mines, and they generally, after investigation, are satisfied that we have a great mining country. Of course, the excellence of this, as a mining country, is as yet mostly in perspective, for the development of our mines, so far, is a mere bagatelle to what it should be, and will be; but we have enough of development upon our mines already to convince one who is expert in such things that they are all we claim for them.—*Arizona Enterprise.*

MECHANICAL PROGRESS.

Working Steel.

We have given several paragraphs of late on points connected with steel working. The subject is of such importance to all metal workers that we take it up again. Miller, Metcalf & Parkins, of Pittsburgh, Pa., issue the following through the *Iron World*, as the result of their wide experience:

Owing to varying instructions on a great many different labels, we find at times a good deal of misapprehension as to the best way to heat steel; in some cases this causes too much work for the smith, and in other instances disasters follow the act of hardening.

There are three distinct stages, or times of heating: First, for forging. Second, for hardening. Third, for tempering.

The first requisite for a good heat for forging is a clean fire and plenty of fuel, so that jets of hot air will not strike the corners of the piece; next, the fire should be regular, and give a good uniform heat to the whole part to be forged. It should be keen enough to heat the piece as rapidly as may be, and allow it to be thoroughly heated through, without being so fierce as to overheat the corners.

Steel should not be left in the fire any longer than is necessary to heat it through, as "soaking" in fire is very injurious; and on the other hand it is necessary that it should be hot enough to prevent surface cracks, which are caused by the reduced cohesion of the overheated parts, which overlie the colder center of an irregularly heated piece.

By observing these precautions a piece of steel may always be heated safely, up to even a bright yellow heat, when there is much forging to be done on it; and at this heat it will weld well.

The best and most economical of welding fluxes is clean, crude borax, which should be first thoroughly melted and then ground to fine powder. Borax prepared in this way will not froth on the steel, and one-half of the usual quantity will do the work as well as the whole quantity unmelted.

After the steel is properly heated, it should be forged to shape as quickly as possible, and just as the red heat is leaving the parts intended for cutting edges, these parts should be refined by rapid light blows, continued until the red disappears.

For the second stage of heating, for hardening great care should be used; first, to protect the cutting edges and working parts from heating more rapidly than the body of the piece; next, that the whole part to be hardened be heated uniformly through, without any part becoming visibly hotter than the other. A uniform heat as low as will give the required hardness, is the best for hardening. Bear in mind that for every variation of heat, which is great enough to be seen, there will result a variation in grain, which may be seen by breaking the piece, and for every such variation in temperature, there is a very good chance for a crack to be seen. Many a costly tool is ruined by inattention to this point.

The effect of too high heat is to open the grain; to make the steel coarse.

The effect of an irregular heat is to cause irregular grain, irregular strains and cracks.

As soon as the piece is properly heated for hardening, it should be promptly and thoroughly quenched in plenty of the cooling medium, water, brine, or oil as the case may be.

An abundance of the cooling bath, to do the work quickly and uniformly all over, is very necessary to good and safe work.

To harden a large piece safely, a running stream should be used.

Much uneven hardening is caused by the use of too small baths.

For the third stage of heating, to temper, the first important requisite is again uniformity. The next is time; the more slowly a piece is brought down to its temper, the better and safer is the operation.

When expensive tools, such as taps, rose cutters, etc., are to be made, it is a wise precaution, and one easily taken, to try small pieces of the steel at different temperatures, so as to find out how low a heat will give the necessary hardness. The lowest heat is the best for any steel; the test costs nothing, takes very little time, and very often saves considerable losses.

ARTIFICIAL HONE.—The smiths at Ceylon use a composition as a hone for sharpening knives and cutting instruments that is worth noticing. It is made of the capilla resin and of corundum. The corundum, in a state of impalpable powder, is mixed with the resin rendered liquid by heat, and well incorporated. The mixture is poured into a wooden mold, and its surface leveled and smoothed while it is hot, for when cold it is extremely hard. It is much valued by the natives, and preferred by them to the best of our hones.

PARISIAN RAILWAYS.—The Parisians are to have a system of underground railways similar to those of London. The total length will be 16 miles and the cost 160,000,000 francs. A double tunnel, lined with brick, will be employed, and the central station will be 21 feet beneath the level of the Palais Royal garden.

Stone Sawing with Shot.

Concerning the substitution of iron shot for sand in stone sawing, the *Polytechnic Review* gives the following detailed instructions for carrying out the process: "The method of sawing with the iron shot is similar to sawing marble with sand, and the same saws may be used, but for granite stronger and heavier frames are better, and blades $\frac{1}{4}$ " thick by 6" or 8" deep allow more pressure and cut faster and straighter than blades $\frac{1}{4}$ " thick by 4" deep. When starting with new iron shot, mix about 20 lbs. sand and 10 lbs. paste of slacked lime with each 100 lbs. of shot; the sand is to make it lighter and work better with the water drip; the lime is to prevent the rusting of the shot, and staining the stone. Use as little water drip as possible; it cuts better when the sludge from the ends is rather thick. Throw back this sludge of shot and mud to feed the saw, without washing it, until the mud gets too thick, then wash it partially. No sand is needed after the first, as the mud supplies its place, but keep up the dose of lime, as it gets washed away. Too large a feed of the shot is bad; about 25 lbs. per hour of feed to each blade does well. The rapidity of cutting depends upon the pressure used. A frame 11 feet long, weighing 1,800 lbs., swinging on iron rods three and one-half feet long, making 90 double or 180 single strokes, 20" long per minute, on a block of Quincy granite (as hard as Aberdeen) five feet long, with five blades, $\frac{1}{4}$ " thick, went down one inch per hour; with three blades it went down one and fifteen-sixteenths inches per hour; with two blades it went down three inches per hour. A pressure on the blade equal to 400 to 600 lbs. per foot length of kerf is desirable. A short, stiff blade, pressed down by screws, went down into a block of Quincy granite one foot long, 16 inches deep, per hour.

"Marble is cut from three to four times as fast with shot as with sand, in the same saws, and takes about one-half the power in proportion to the quantity sawed, all the power consumed in uselessly crushing the sand being saved. A blade $\frac{1}{4}$ " thick was worn away one inch in cutting 48" deep in granite, or 250" deep in marble. The mud from washing is run into catch-pits; the fine particles of iron thus saved are used for smoothing granite, and cut faster and last longer than emery. Hard sharp-sand, in being ground to finest mud, will wear away about its own weight of glass; coarse grained emery, about twice its weight; iron shot, passed through a No. 70 sieve, wore away 50 times its weight of glass. All journals and rubbing surfaces of the machinery should be carefully protected from the shot, as they cut and tear far worse than sand."

PREVENTING CORROSION OF IRON.—Prof. Barff recently delivered a lecture on a treatment of iron for the prevention of corrosion, which promises to greatly extend the usefulness of the most useful of all metals. The temperature of the articles to be protected is raised to about 500° Fah. in a suitable chamber or muffler, to which steam is admitted. The articles having thus been exposed at a high temperature in an atmosphere of superheated steam, the black or magnetic oxide is formed on the surface. This oxide is credited with the quality of putting a stop to further oxidation, whereas the ordinary form of oxidation or "rusting" grows on what it feeds, serving as a carrier for atmospheric oxygen to the iron to almost any depth. The black or magnetic oxide produced as above described forms a coherent and adherent coating which is not subject to change in the presence of moisture and atmospheric oxygen, and which is not decomposed in any temperature to which iron is exposed in its ordinary uses. Hence this treatment may be used for the protection of iron used for street mains, for iron instead of lead service pipes, for household utensils of all kinds as a substitute for tinning, and for all kinds of architectural ornaments. Prof. Barff makes no estimate of the cost of such treatment, but it is claimed to be less than the cost of galvanizing or tinning kitchen articles. The oxidized surface is said to be much harder than the surface of iron not thus treated, so that the durability of the articles would be as great or greater than that of similar untreated articles.—*Philadelphia Ledger*.

AN ELECTRIC BIT.—The French papers describe an invention for driving a horse by electricity. The coachman is to have under his seat an electro-magnetic apparatus, which he works by a little handle. One wire is carried through the rein to the bit and carried to the crupper, so that a current once set up goes the entire length of the animal along the spine. A sudden shock will, we are gravely assured, stop the most violent runaway or the most obstinate jibber. The creature, however strong and vicious, is "transformed into a sort of inoffensive horse of wood, with the feet firmly nailed to the ground." Curiously enough, the opposite effect may be produced by a succession of small shocks. Under the influence of these the veriest "scrub" can be endowed with a vigor and fire indescribable, and even the Rosinante of Don Quixote would gallop like a Derby winner.

STEEL RAILS.—The first steel rails laid on the Lehigh & Susquehanna Division railroad cost \$250 a ton in gold; such rails can now be bought for \$50 a ton.

SCIENTIFIC PROGRESS.

Points on Coal Deposits.

Prof. Williamson, of Owen's College, Manchester, England, lectured recently at Barnsley, taking for his subject "A Piece of Coal." Of the manner in which the coal deposits were made, he said: "In America there were seams 30 feet in thickness, some by the side of a river—but how did the plant get there? Some of our navigators had noticed the fact that in sailing in the Gulf of Mexico large masses of vegetable matter, rafts of trees and branches, had been brought down by the Mississippi, washed away by floods from the banks of the river, and carried into mid-ocean. When these rafts became so thoroughly water-logged that they could float no longer down they went to the bottom, and these navigators came to the conclusion that that process was the history of the formation of coal. But this explanation did not satisfy everybody. Some people, however, were of opinion that the explanation would be found in the history of our peat bogs. Some light was thrown on the matter in the making of the railway between Bolton and Manchester, by Mr. Hawkshaw, the engineer.

"In superintending the work he found at Clifton some fossil trees standing on the coal, the roots coming down to the coal. The stem was not less than 12 feet in circumference, with enormous roots. It was clear that these trees had grown where Mr. Hawkshaw found them, standing in the precise spot where the seeds were shed millions of years ago, shooting up and growing age after age. Consequently it was fully established that coal was made of various matters contributed by trees where it was found. In Lancashire they had from 20 to 30 beds of coal, and how did they get there? The levels of land and sea were constantly changing, and were changing at the present time. The old sea line can be traced high up on the Swedish and Norwegian mountains. It was the same in South America. If they went to the middle of the Pacific ocean, where thousands of years ago there were huge continents, the levels were going down, wherever they had volcanoes in an active state the land was rising, and wherever they had coral forming their reefs the land was lowering. If they went to the sea coast between Manchester and Liverpool they would find a submarine forest, with stumps of trees washed over by the tide. The land there was sunk and the salt water was washing the mud over the area, gradually filling up the places, and so coal would be formed years ago. The same thing existed formerly, and the sea had covered forests with fine mud, and the quality of the coals depended on the kind of routine they were subjected to. With regard to the various qualities, they would notice that whilst the floor of the bed was always the same fire-clay, the roof varies a great deal. In some places it was a dense blue clay, in others a sandstone, and the beds themselves broken and shattered by some tremendous action by a marvelous and mysterious arrangement. If those strata had remained in horizontal layers they would have been far out of the reach of man, but by some mysterious power they are turned up and twisted and brought near to the surface. They were brought within reach because there had been wonderful agents at work which tore up the earth's crust, and there are no strata so ancient but had been brought to the surface at some point. Such had not resulted from any volcanic action, but from shrinkings and contractions which the earth's crust had undergone."

A NEW PHOTOMETER.—A new pocket photometer has lately been described to the French Society of Photography by M. Schutte. The instrument has the form of a small telescope. Putting the eye to the narrow end and looking through at a light, one sees a small, luminous circle, on which is detached some figure in black. On turning the wider part of the instrument, successive numbers are seen, and the higher the number the weaker is the light perceived, and at length it quite disappears. This effect is obtained by means of leaves of waxed paper, the number of which increases with the figures. Thus a weak luminous source does not allow one to see the same number as a strong one, and the variation between the figures increases with the difference in intensity. The instrument can be used for determining the time of exposure in photography.

CLIMATIC CHANGES FROM COAL BURNING.—Mr. H. S. Eaton, President of the British Meteorological Society, estimates that the heat developed from the present annual consumption of 5,000,000 tons of coal on the metropolitan area of 118 square miles, and from all other artificial sources, would suffice to raise the temperature of a stratum of air 100 feet in depth resting on that area 2.5° every hour. The climate of London has been greatly modified during the present century by its great growth in population and corresponding consumption of fuel.

CARBONIC ACID IN AIR.—The open air commonly contains about 3.34 parts, by volume, out of 10,000; according to Pettenkofer any excess over 1 part in 1,000 is unwholesome. E. Schulze thinks Pettenkofer's limit is too low. In a club room he found 37 parts of carbonic acid, and in a school room from 14.4 to 35.6 parts out of 10,000.

Theory of Luminous Flames.

Dr. Karl Hinmann has published an elaborate discussion on this subject, in which he concludes that the theory of Davy must be altered, but need not be replaced by a new hypothesis. From a discussion of the work of previous observers, and a variety of experiments on the diminution and restoration of luminosity in hydrocarbon flames, and on the distance between flame and burner, he arrives at the following conclusions, as stated by the *American Journal of Science and Arts*:

1. The fact that a gas flame does not rest upon the burner, nor a candle-flame upon the wick, as also the fact that a flame never directly touches a cold body held within it, is to be explained by the cooling action exercised upon the gas by its surroundings. The combustible gases are cooled throughout a definite space below their ignition-temperature; the flame is therefore extinguished. This conclusion is opposed that of Glochmann.

2. The very considerable distance noticed between the burner and the flame of a gas issuing under high pressure, or mixed with a large column of an indifferent gas, cannot be accounted for on the grounds put forward by Bonevides. The production of such a distance is much rather to be traced to the cooling action of the stream of gas and of the outer air, and perhaps more especially to the fact that the velocity of the stream of gas in the neighborhood of the burner is greater than the velocity of propagation of ignition within the gas.

3. In order that other circumstances conditioning the effect may be removed, the velocity of propagation of ignition must be equal to that of the gas-stream at the point, situated some distance from the burner, where the flame begins.

Determination of the velocity of ignition should be made under these conditions for different gases, and since this magnitude is a function of the difference between ignition and combustion temperatures, conclusions may be drawn from such experiments regarding the relations existing between these points.

4. The velocity of propagation of ignition may be easily determined for solid and liquid combustible bodies; and the numbers so obtained may be regarded as comparative quantitative expressions for the liability to ignition of these substances.

PREHISTORIC MICA MINING.—In a paper read before the New York Academy of Sciences by A. A. Julien, on prehistoric remains in western North Carolina, a minute delineation was made of an extensive series of ancient excavations extending from Mitchell county southward into Georgia. These cuttings were evidently executed for the purpose of mining for mica and steatite—an industry still actively prosecuted in the region. The coarse granite strata containing the mica are divided into soft and hard bands, which have influenced the character of the mining both in prehistoric and present times. The ancient workings have been discovered in the soil veins, and consist of two classes. In one deep shafts have been found, sometimes containing tools; and these are ascribed to the Spaniards or to still later adventurers. The other class consists of open excavations, occasionally connected with small tunnels; and these are pronounced undoubtedly of prehistoric origin. Ashes have been discovered in some of the mines, showing the use of fire, as in the tunnels of Lake Superior mines. From appearances it is judged that vast quantities of mica have been taken out in prehistoric times; and it is considered that in these mines the source has been discovered of the mica plates extensively used in tombs of the Mound Builders of the Mississippi valley.

SPECTROSCOPIC EXAMINATION OF THE RAINBOW.—Taking opportunity, lately to observe with a Nicol's prism an uncommonly fine rainbow, which spanned the Oesthal in Baden Baden, *Nature* says: "M. Schiel found that with the prism in a certain position, the colors disappeared completely, and the prism was pretty dark. But on turning it through 90°, the bow appeared again in all its brilliancy. The rainbow is, therefore perfectly polarized light. Several rainbows observed since have shown the same behavior; but apparently only a very bright colored rainbow presents dark on the field of vision with the corresponding position of the prism."

FORMATION OF SULPHUR SPRINGS.—M. E. Plaugaud found near the source of a mineral spring, strongly impregnated with sulphur, a number of fine convolve, which he washed carefully and left in a flagon of ordinary water. About eight days afterwards, wishing to re-examine them, he was struck with the strong sulphurous odor which escaped the water. He then instituted experiments, which led him to conclude that sulphurous mineral waters owe their formation to the reduction of diverse sulphates, under the influence of living bodies, which act as ferments.

STAR-TWINKLING AS A SIGN OF RAIN.—Humboldt observed that in tropical regions the approach of rain is often announced by the twinkling of stars near the zenith. Montigny observed the intensity of the twinkling for 230 evenings, and found that it increased if a storm or a barometric depression was approaching. When rain is foreboded the glimmer is especially strong.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

THE ADVANCE BONANZA.—*Alpine Chronicle*, April 21: The Advance mine continues to develop grandly, and everything relating to the work in and about the mine is progressing satisfactorily. Three shifts are working in each drift, and a No. 2 Root's blower gives excellent air in the mine. The west drift is 80 feet in the ledge, and the whole face in pay ore. The foot-wall not yet reached. The north drift, running in the eastern casing of the ledge, is in 35 feet—all in pay rock—from which point they are cross-cutting east and west, and have already run 16 feet in good paying ore, the westerly face containing high-grade ore, the quality improving as it approaches the ledge proper. Having visited the mine this week, we can assure our readers that the Advance ore body is simply immense, and were it on the Comstock, the stock would go up to the highest figure. The company will put its mill in good order as soon as possible, and expect to be shipping bullion before the first of June.

O'HARRA FURNACE.—It is gratifying to know that the O'Hara champion furnace, recently put in operation at the Exchange mill, has proved a success and been accepted by Manager Chalmers.

AMADOR.

OLIVE.—*Amador Ledger*, April 21: Sinking continues on this prosperous Drytown mine. The shaft is now down 70 feet, the ledge varying from four to seven feet. It is a noteworthy circumstance that the rich specimens which marked the claim in the earliest stage of its development, are no longer met with. The gold now appears to be more evenly distributed through the quartz, but little free metal being discernable, nevertheless the rock is expected to rival that of the first run, which gave up \$18 to the ton. John Greenwell is general Superintendent, with A. J. Burns as foreman. The Bonanza mill is engaged for another crushing of the rock in May.

YELLOW JACKET.—This claim is the south extension of the Crown Point ledge, at Drytown. A limited amount of work has been done, the dirt and rock taken at various points yielding several dollars to the pan. So far work has been prosecuted at a considerable elevation above the creek, and it is thought probable that when the level of the stream is reached a permanent ledge will be struck.

YORK'S GRAVEL CLAIM.—The clean-up on this mine, at Butte City, for a run of 30 days, was finished this week. The result is between \$1,500 and \$1,600 in gold. This is considered satisfactory, though not so good as the sanguine pictured.

COMET.—There is no doubt that an important strike has been made on this mine. We were shown on Saturday a sample of rock taken from the shaft that morning. It was that dark-looking character, full of sulphurets, with one or two patches of coarse gold.

OSIDA.—Twenty stamps are kept running steadily on rock from the lower levels. The old shaft is being repaired, and sinking will be the next thing in order. The Onida takes rank among the largest mines in the county, giving employment to a small army. The ore has chiefly been of low grade, and the nature of the ground being such as to require heavy and frequent timbering, involving much expense, the proceeds have mostly been swallowed up for working expenses. The lowest level is 1,100 feet down. It is now proposed to go 200 feet beyond this.

WHEAT.—The first clean-up of this mill was made this week. The precise amount realized is not yet known, the returns from below not having been received. From the quantity of amalgam shipped, it is safe to estimate the total yield at \$5,000, an average of \$13 to the ton.

CALAVERAS.

MOUNT TOLSON.—*Calaveras Chronicle*, April 21: A contract has been let to sink a shaft in a Mount Tolson mine, Jesus Maria district, 50 feet deeper, with the privilege of 100. Should the ledge show well upon the completion of the sinking, 25 more stamps will be added to the battery and hoisting works put up. We learn that the Baron von Gleichenberg has assumed the duties of Superintendent.

BLAST.—A blast of eight barrels of powder was set off in the Yelch mine on Monday last, doing good execution. **READY TO CRUSH.**—Gamble & Co., at Railroad Flat, have out quite a quantity of rock, which is to be crushed in Clark's mill. Everything is in readiness to commence hauling, and the stamps will probably be set at work Monday. Clark's mill has lately been thoroughly overhauled and repaired.

GRIN MIXT.—The work of running the 1300-ft level in the Grin mine is progressing. The ledge showed 15 feet wide in the cross-cut near the shaft, but as the level is run it narrows. The rock obtained so far is not first-class, but, as in the levels above, it will undoubtedly improve as work progresses.

EL DORADO.

GOOD NEWS.—*Mountain Democrat*, April 21: Arrangements have been consummated for a transfer of the Pacific mining property in the points of Placerville, from the hands of the present owners, an English company, to a new company, one-half of the stock of the latter to be held here and one-half by San Francisco capitalists. When it is understood that the same parties who control the St. Lawrence mine will control the Pacific under the new management, the public will feel assured that the Pacific "means business." As a measure of prudence, and to infallibly establish what is already beyond reasonable doubt, one extensive crushing of ore from the Pacific mine will be made at the Brewster mill, and if that realizes expectations a large 20-stamp mill, with all of the latest improvements, will be immediately erected on the Pacific ground.

NEW DITCH SYSTEM.—The Park canal and mining company, successor to the old Eureka ditch company, is inaugurating a new system of ditches which will afford adequate supply of water, not only for their own mine at Dry gulch, but for the large belt of auriferous gravel lying further to the west. A ditch nine miles in length will take up the water of the North fork of the Cosumnes and carry it into Camp creek, above the Baltic mill. A five-mile ditch will then take it over to Park creek, where the company have two of the finest reservoir sites in the mountains. From Park creek a ditch already constructed will carry it to the summit of the divide between the Cosumnes and Webster creek. With the aid of the Sly Park and Hazel Dell reservoirs for storage purposes, the supply of water will be made continuous throughout the year, and we may confidently look forward to a rich return from the mines of that portion of our county.

LAWRENCE.—The Lawrence mine next Monday week. Simultaneous with the sinking of the main shaft from the 800-ft level, they have been running north from the old workings on the 300-ft level, at which point they have opened up a large body of fine ore, apparently extending indefinitely to the northward, and already demonstrated as having an extent of 130 feet up and no working. There are now about 300 tons of this ore on the dump and the work of extraction goes bravely on.

EXCELSIOR.—The flume of the Excelsior mine is being extended across the Diamond Springs road, through a heavy cut, to Slaughter House ravine. The extension will make this flume more than a mile in length.

INYO.

MINNETTA MILL.—*Coso Mining News*, April 21: From R. C. Jacobs we learn that the mill at the Minnetta mine started up on the 17th instant, on a batch of 20 tons of ore, simply as an accommodation to some prospectors at work on their mines near Snow's canyon. The ore is very rich, and Mr. Jacobs thinks it will yield \$200 to \$300

per ton. The owners are Messrs. Woodman, Higgins, Gannon and others. As soon as this batch is worked, Mr. Jacobs will start the mill on the regular contract with the Minnetta company, which will keep the mill running steadily for six months. He expects to clean up \$1,600 to \$2,000 every 24 hours. The ore, so far as tested, averages \$100 per ton.

NEW COMPANY.—A company has been formed in New York to mine and mill in Lookout district. The parties are expected here next week. They own some very rich mines in the vicinity of Snow's canyon, and are now having small batches of rock worked at Jacobs's mill, as a test prior to beginning work on a grand scale.

MINNETTA BELLE.—This mine, under the management of Mr. C. S. Peck, the new Superintendent, is looking well. Three men took out 50 tons of ore last week, which will go from \$100 to \$150 per ton. The mine is being worked in a new place, and is said to far exceed any opening heretofore made.

CONTRACT LET.—*Inyo Independent*, April 21: Last week Mr. Elsbeth, pursuant to instructions from the company below, let a new tunnel contract on the Kearsarge mine, and the work of driving it is now going on. It will be remembered that the contract on the original tunnel was thrown up last winter, having then been driven about 150 feet. The new tunnel begins about midway of the old one, diverging at almost an angle of 40° and is expected to strike ore in 50 feet.

GRASS FLAT.—The Union Con. company have effected a general reduction of 50 cents per day on the wages of all of their employees—superintendents, furnace men, engineers, miners and laborers. So far as we have learned none of the men have quit in consequence.

NEVADA.

NEW LADDER STRUCK.—*Grass Valley Union*, April 25: Harsch and Wiley have struck some very fine rock north of Cincinnati hill, and think they have the main ledge running through that vicinity. The ledge appears to be large and contains good sulphurets, and free gold is visible in the rock. This ledge is near the famous ground called the "Never Sweat," and when this ledge was worked several years ago, Jas. W. P. considered the name Never Sweat not appropriate, but a good burlesque. A great many shafts have been sunk in that vicinity, and found only indications. If Harsch and Wiley are correct about being on the main ledge, they are owning a valuable property.

PLACER.

YOU BET MIXT.—*Dutch Flat Forum*, April 19: The Nece & West and Waloope companies turned off last week and made a general clean-up. The results are reported to be very good. The water has been turned on and washing again resumed. The Nevada company and Hussey company continue to wash under favorable circumstances.

LOWELL HILL.—Work in the Swamp Angel mine is being prosecuted under favorable circumstances. As the mine advances new drifts are being opened, which look and prospect well with an assurance of paying regular dividends.

LITTLE YORK.—The Empire and Christmas Hill companies are making splendid headway in washing. The ditches continue running full.

REMINOTON HILL.—Ground sluicing continues in the Rhode Island mine without abatement. The result is said to be good. Both the Rhode Island and the Wide West mine, the distance between the two now being 170 feet, which block of ground will be left solid, with the exception of connecting air drifts, until the boundary line of the mine is reached, it being a distance of 2,100 feet. The gravel taken therefrom continues to be exceedingly rich. A drift is being opened east of tunnel No. 2, to test the width of the channel, and breasting out of the same will be commenced immediately.

FALL CREEK.—The Wood & Porter claim is located on Fall creek, being one and a half miles west of where the Culbertson grade crosses the stream, and nine miles north of Emigrant Gap. It contains 40 acres of ground, the gravel having an average depth of 70 feet, and has sufficient elevation above the stream to insure its successful working by hydraulic, under which process it will be a remunerative investment. This has been proven by prospecting the gravel by ground sluicing. Fall creek, at this point is quite rich, the gravel being about 10 feet deep, but there is not sufficient grade to work it otherwise than to pick and shovel it into sluices, and as this ground will have to be worked before any hydraulic is done, the same is now progressing under slow but paying circumstances, and will take about one year to complete. Our informant, Mr. Wood, one of the owners, thinks that profits enough will be realized to fit up and put the mine in condition for hydraulic. There are also several other mines in this vicinity, which are thought would pay well if properly worked, as the prospects in several instances are said to be promising.

RATN.—*Dutch Flat Forum*, April 19: Since our last we have been favored with heavy showers of rain, which filled the various ditches to overflowing, and deposited several inches of snow on the mountains. The Baker claim had its shaft plugged by a blast last week, and did not succeed in opening it till yesterday. The extent of the work necessary for accomplishing this object can be better realized when we state that it not only was the 90 feet of shaft filled with gravel, but it was covered over to a depth of 70 feet with gravel and boulders. It is clear now, however, and is expected that nothing will be continuing to work the mine, excepting when it is necessary to turn off to break up boulders and the chunks of cement below. The Star & Union continues washing nights, and removing boulders in the day. The Southern Cross and Polar Star claims are in the same fix as the Baker was. In the latter the tunnel is plugged, and an extra string of pipe is being extended down the incline so as to wash the debris away from below. The Pacific claim is refitting and moving the pipe so as to attack another point of promising gravel. As Gold Run the Big Bonanza, Hogskin, North Star and Illinois claims continue washing. The Cedar claim, belonging to the Gold Run hydraulic mining company, limited, cleaned up on Tuesday, with very satisfactory results, considering the character of the gravel that is available.

AT THE FRANKLIN.—As the work advances, the effect of the new plan can be readily seen. The gravel is thoroughly pulverized, and melts away like snow before the streams directed against it. The large derrick, under the supervision of Mr. J. J. Brady, is kept at work all the time removing the boulders that accumulate. The gravel is improving in appearance, and Mr. Teaff expects a better clean-up this time. In every respect the work at this mine, under the able management of Mr. Teaff, is progressing rapidly in the most favorable manner.

PLUMAS.—*Plumas National*, April 21: Another gang of Chinamen have been put to work in the Golden Enterprise claims, near Spanish ranch, and Mr. Jack informs us that he intends to extend his big flume as fast as the cut is opened. The work is progressing very bravely, and by the last of July will have the head of the flume in pay gravel. As the flume is made double, and as there is always water enough to run one side of it, we shall look for "Uncle Dick" to have his pockets full of "dust" this fall.

QUARTZ.—The recent discovery and sale of the Ellis ledge on Soda creek has caused an excitement on the other side of the range, and many are now coming every day. Everybody has the quartz fever, and old and young are in the mountains from daylight till dark, searching for "croppings." It is said that so strong is the mania that ranchers are expecting trouble to find farm hands. Numerous locations are being made daily, and occasionally one that has much real merit in it. There is no doubt but that some valuable quartz property will be developed, and that the "fever" will bring forth many good results.

SIERRA.

RICH FIND.—*Mountain Messenger*, April 21: On Tuesday last the people of Forest City were electrified by the news of the striking of a rich quartz ledge in the North Fork company's new tunnel. So far as prospecting at this writing, the ledge is about four feet wide, carrying a vein of arsenical sulphurets about six or eight inches wide, besprinkled with free gold. A ton of such rock, as the specimens we have seen would yield probably \$25,000 to the ton, perhaps more. It is confidently anticipated that the company will get enough out of this find to pay all expenses incurred in opening their claim. The lead is a blind one, having a heavy body of cement over it. The foreman, Watson Bayles, said that if the vein continued he could get a ton of the sulphurets out in a day.

SCALE'S DRIFTING.—The Cleveland & Sierra hydraulic company are cleaning up with prospects of good returns. They put up a new and powerful water derrick, but cannot use it this season. Fair play will reap a golden harvest this year. Everybody is at work. This is one of the most prosperous little mining towns in the county. Water season will probably be short.

LOW.—The incline of the Iowa is down about 500 feet. Seventeen men busy outside and underground. Everything is in excellent order. Repairs being made as needed. A contract for 600 cords of wood to be let soon. At foot of incline it is proposed to run a branch tunnel into the hill, a second to the right, some 80 feet, and then off at right angles to the front. We trust that the Iowa boys will soon realize the handsome dividends that should reward their perseverance and hard work. Their efforts will result in the opening of innumerable new adjoining claims, as this is believed to contain one of the most extensive gravel deposits in Sierra county.

GRASS FLAT.—Pioneer company have worked off two large claims this year, and are now cleaning up with prospect of good pay. Employ 15 men.

ST. LOUIS.—Morgan & Donahue's claim will do as well as usual this year, notwithstanding the light snow fall. Cleveland company's contract with the company's contract with W. H. Prosser, Esq., of 100 feet tunnel, nearly completed. Empire company paying larger dividends than ever; working 100 men. The Empire company are daily approaching the ground of the Fashion and Sierra Extension companies, and the latter are much encouraged by their future prospects. Sears Union water company are still plying away at the banks, with fair prospects of doing well.

NEWARK.—No Plus Ultra company are in nearly 3,000 feet. Intend soon letting a contract to extend the tunnel or raise, the supposition of many being there is gravel overhead, with prospect of its being good. North America company are opening double track in 1,700 feet—run mules—150 men employed. Bright prospects of good returns. M. Schofield, Esq., Superintendent. McQuestin still works the gravel, etc. Everything has been rebuilt. Swiftsure company are running a new tunnel above the old, making a connection between the two for air, when they will be taking out pay. Roach & Sayers intend opening their claim soon.

GIBSONVILLE.—Michigan company are completely fitted up—in good gravel, but rather hard upon the main lead of the channel opening out. W. B. Russell, foreman; six men employed. Union company are working 43 men, obtaining 100 cords of gravel in over 3,000 feet of good, soft gravel. F. Salter, foreman. Gravel Hill hydraulic company washed off two claims. Good pay was found last year, and they expect to do as well this season. Eight men employed; more needed soon for cleaning up. Nat Hersom, foreman. Keifer & Emerton are working eight hands; good pay. Chaledon company are employing about 60 hands; tunnel in 2,500 feet; paying well. John Johnson, foreman. The gravel is of good quality and rest, is now enjoying flush times again. About \$10,000 is paid out monthly for wages by the mining companies hereabouts, which makes money very plentiful and times lively. The prospect is that they will continue good for an indefinite period, and also improve very much in the years to come.

PORT WINE.—This place changes less of all the north to the south, and there's no hope, and there may possibly, even with the present gloomy outlook, be a bright future in store for Port Wine. Union company are running a prospect tunnel into Bald hill. Chances favorable. Monte Cristo company are taking out pay. Indian Queen company are realizing wages. Highland Mary company are still running a hard bedrock tunnel, the present length of which is near 700 feet. Pay gravel is supposed to be only a few feet ahead.

TRINITY.—*New River*, Trinity Journal, April 21: We understand that considerable activity is being manifested in this part of the county—water rights located and improvements of a permanent character being made. From the character of the gold found there in former years, it would seem as if the deposits could not have been exhausted by the limited population which found its way over the New River mountains. Fifteen years ago the New River country was a pretty prosperous one. There was a large population, Pony creek, Virgin creek and other branches of the main stream, and "big chunks" abounded. The hard winter of 1861 blocked the roads, and many had to come out where provision could be had, and this was followed by the Indian troubles, which continued for years, and effectually scattered the people of New River. The bed of the stream has been almost wholly given up to Chined of late years, but there are many high banks and bars which would seem ought to pay well for working. No doubt if the improved machinery in use among the miners in this part of the county was introduced in that region and put to work in some of the numerous bars or flats which line the stream, New River would show some claims worth owning.

Nevada.

WASHOE DISTRICT.

BELLISH.—*Gold Hill News*, April 25: The material encountered in the face of the east drift on the 1800-ft level is gradually softening and is of a much more favorable kind.

BEST & BELCHER.—The south cross-cut, No. 3, near the south line, on the 1700-ft level, is in a distance of 230 feet, the face in vein matter. Cross-cut No. 2, near the center of the mine, on the same level, is in 176 feet the average rate of progress of these drifts is about five feet per day.

CALEDONIA.—Sinking the shaft has been resumed. ATLANTIC CON.—The tunnel is being pushed rapidly ahead, following the vein, almost the entire face in ore.

CROWN POINT.—Yesterday afternoon the advance drift in the face of the east drift on the 200-ft level broke through the vein porphyry in a sedimentary formation through which the drift has been running for the past week, and tapped a strong flow of scalding hot water. Knowing the fearful pressure of water likely to be encountered when the ledge was tapped, Superintendent Samuel Jones had taken every precaution to draw the water gradually and prevent the flooding of the mine. Fearing that the fierce current would break through the drill hole, it was at once partially plugged and work in the face of the drift temporarily suspended, until the supply of water began to lessen. The distance between the 2000-ft level and the 1700, the next level above, is 300 feet perpendicularly and nearly one-third more when we take into consideration the inclination of the ledge. This gives a fearful pressure, but the Superintendent having a great deal of experience in the past in this character of work, determined not to let the flood get the best of him if precaution can prevent it. Large sized Cameron pumps are used to hoist the water from the 2000 up to the 1700-ft level, where it is carried in sluices through the Belcher combination pump shaft. The pumps are running this morning at the top of their speed and are keeping the water well under control. Should the water show a gain on the pumps, others ready to insert. The Belcher combination shaft is down 1,970 feet.

BELCHER.—Daily yield, 55 tons of ore. The ore is being crushed as fast as it is extracted, and will yield a net profit which will more than pay the running expenses of the mine during the month. The net bullion production of the mine for March was \$25,000, which amount will be greatly increased by the April returns. The new pumps are now taking the water from the Yellow Jacket, Crown Point and Belcher mines, and handles it with perfect ease.

JEWICK.—Daily yield, 450 tons of ore, keeping the mills crushing to their fullest capacities. The ore stops on the 400, 600, 700 and 800-ft levels are showing finely and yielding good milling ore at all points. The vein matter on the 1150-ft level thus far encountered is of a much livelier character than was that of the levels above as the same distance from the vein.

YELLOW JACKET.—The foundations for a large and permanent building are being laid at the new shaft. This building will be erected so as to entirely inclose the present works.

HALE & NORCROSS.—The pumps have been kept steadily at work at the average rate of six and a half strokes per minute for the past week, and have during that time been making a steady and constant gain on the flow. The temperature of the water at the bottom ranges from 140° to 150° Fah. The temperature of the air in the main incline varies from 96° to 100°.

CON. VIRGINIA.—Daily yield, 450 tons of ore. The ore stops on the 1650-ft level continue to open up finely and are yielding rich ore. The mills are kept steadily running up to their full crushing capacities. The face of the south drift on the 1650-ft level, running to connect with the deep winze, continues in rich ore. The stops on the 1550-ft level continue to yield good ore, and the upraise in that portion of the mine shows the ore prospects to be of a much more favorable and lasting character than has heretofore been expected.

CALIFORNIA.—Daily yield, 500 tons of ore. The mills have all been steadily running during the week, with the exception of the Con. Virginia mill, which was delayed 36 hours by the breakage of the crank of the driving engine. The ore breasts are showing splendidly at all points, and the yield of bullion, notwithstanding the delay of the Consolidated mill, is already in excess of that for March. This insures the payment of the regular dividend in May.

GORT & CONLEY.—The pumps are kept steadily running about 11 hours out of every 24. The machinery is all working splendidly.

OVERMAN.—The south drift on the "1300-ft level" is advancing, the face in a fine character of quartz. Preparations are being made to sink a winze on the ore below that level.

SOUTH COMSTOCK.—Bottom of shaft still in good sinking ground, with encouraging prospects. It is well timbered and in good condition for active work in case the expected good ore developments should be encountered.

OPHIR.—Daily yield 30 tons of ore. The ore is being crushed at the Windfall mill and is yielding about \$40 per ton. An air-connection has just been completed between the 1000 and the 1300-ft level, which greatly facilitates getting at the ore, and will enable an increase of 40 tons per day.

JOHN THOMAS.—The face of the main drift at the 600-ft level shows very good looking vein of low grade ore, which is expected to lead to something better before long.

JULIA.—The main south drift, on the 1800-ft level, is steadily advancing, the face in ore which appears to be gradually widening and increasing in value as the drift progresses. The improvement in the character of this ore is a great encouragement.

MEXICAN.—The upraise from the 1305-ft level is making excellent progress, the entire face in quartz of a fine character.

SOLID SILVER.—The cave mentioned last week in the main adit or drift northward has been properly checked and secured, the debris cleared away, and the upraise to explore the merits of the ore exposed by it above the tunnel is making good progress.

CHOLLAR FORT.—Daily yield 100 tons of ore, the average value of which is \$25 to the ton.

ALTA.—Sinking the shaft is making the best of progress, the ground in the bottom being softer.

SILVER HILL.—The south drift, on the 650-ft level, is showing some fine quartz and ore.

LADY WASHINGTON.—The quartz in the face of the north drift, on the 800-ft level is becoming more concentrated and is of a much more lively and healthy character.

JAY COX.—The north drift on the 1800-ft level is steadily advancing, the face in vein matter mixed with quartz of a lively encouraging quality.

SUTRO TUNNEL.—Total length of tunnel to-day, 16,627 feet. The face of the header is in hard ledge porphyry, with seams of decomposed quartz and clay, which material is difficult and unfavorable for both drilling and blasting.

NORTH CON. VIRGINIA.—Sinking the shaft is being pushed ahead with all possible vigor.

MINT.—The water is being kept down in the shaft by the use of the tanks.

EUREKA DISTRICT.

TUP. BULLWACKER MINE.—*Eureka Sentinel*, April 21: In the early days the Bullwacker was one of the celebrated properties of this district. It has a shaft to the depth of 320 feet besides other improvements. Large quantities of valuable ore were extracted near the surface, but for the last two years it has not yielded much. Lately Geo. W. Farrell, a thoroughly practical miner, took a lease of the mine for nine months. Going down the shaft about 100 feet he discovered what he supposed to be indications of ore, and at this point began operations. He had only proceeded a few feet when he came on what promises to be a regular bonanza. Assays obtained from the ore yesterday gave \$75 in silver and 65 per cent. in lead. This is certainly very encouraging, and if the prospect holds out it will not be long until the Bullwacker again takes rank as among the big things of the great East.

TUSCARORA DISTRICT.

LOCAL NOTES.—*Tuscarora Times*, April 14: The Grand Central will start up in a few days. Peter Nicholson has a contract to sink 100 feet on the Argenta. Work on the Hornet mine will be commenced as soon as the company can get a donkey engine on the ground. Work on the De Fries is progressing most favorably, and the ore body is being exposed. Capt. Williams, Superintendent. Mr. Wm. Hamilton supercedes Mr. Duval as Superintendent of the mill. Mr. Duval is called back to the Leopard mill. Developments in the Grand Prize are very flattering. The future prospects of the mine was never better at any period of its history.

WHITE PINE DISTRICT.

AS RICH AS EBERHARDT.—*White Pine News*, April 21: The old saying of the ancient White Pine is about to be proved in the early times when the famous Eberhardt mine was producing quantities of the richest silver ore the present century has produced, it was common to hear the hardy miner on Treasure hill speak of his last strike as being as rich as Eberhardt. Mr. Sam. Paul has really developed a body of ore to the southward of the original Eberhardt mine, which he has opened since the halcyon days of White Pine, named the Keystone, and on which he has done but assessment work for the last five years, which is the "same old stuff." Mr. Paul and his son are taking out ore that will work at least \$7,000 per ton. Paul is a mill man and a practical miner, who has constantly been working mines and mills since White Pine was discovered, and for years before in California. Who knows but the old times may come again in White Pine district. Nothing so encouraging has happened for some time as the opening of this body of ore in the Keystone mine.

Arizona.

WEAVER DISTRICT.—*Arizona Miner*, April 13: A company of miners are sinking a shaft in Weaver gulch, half a mile south from this town, and have discovered that, what is commonly called "bed-rock" in this district, is nothing more than a cap of slate, from three to seven feet thick; and beneath this slate are, already, layers of gravel and cement. Their shaft is now down about 80

THE ENGINEER.

Problems for Engineers.

Dr. Siemens made an address at the late meeting of the British Iron and Steel Institute, which is one of the most able and interesting we have read for a long time. We propose to quote a paragraph in which he hints at what is within the possibilities of the future in the way of turning to profit the great force of cataracts and transmitting it to distant workshops. He said: "The advantage of utilizing water-power applies chiefly to continental countries, with large elevated plateaus, such as Sweden and the United States of North America, and it is interesting to contemplate the magnitude of power which is now for the most part lost, but which may be, sooner or later, called into requisition."

"Take the falls of Niagara as a familiar example. The amount of water passing over this fall has been estimated at 100,000,000 of tons per hour, and its perpendicular descent may be taken at 150 feet, without counting the rapids, which represent a further fall of 150 feet, making a total fall of 300 feet between lake and lake. But the force represented by the principal fall alone amounts to 16,800,000 horse-power, an amount which, if it had to be produced by steam, would necessitate an expenditure of not less than 266,000,000 tons of coal per annum, taking the consumption of coal at 4 pounds per horse-power. In other words, all the coal raised throughout the world would barely suffice to produce the amount of power that continually runs to waste at this one great fall. It would not be difficult indeed to realize a large portion of the power so wasted, by means of turbines and water-wheels erected on the shores of the deep river below the falls, supplying them from canals cut along the edges. But it would be impossible to utilize the power on the spot, the district being devoid of mineral wealth, or other natural inducements for the establishment of factories. In order practically to render available the force of falling water at this, and the thousands of other places under analogous conditions, we must devise a practicable means of carrying the power to a distance. Sir William Armstrong has taught us how to carry and utilize water-power at a distance, if conveyed in high-pressure mains, and at Schaffhausen, in Switzerland, as well as at some other places on the Continent it is conveyed by means of quick-working steel ropes passing over large pulleys. By these means power may be carried to a distance of one or two miles without difficulty. Time will probably reveal to us effectual means of carrying power to great distances, but I cannot refrain from alluding to one which is, in my opinion, worthy of consideration, viz., the electrical conductor. Suppose water-power to be employed to give motion to a dynamo-electrical machine, a very powerful electrical current is the result. This may be carried to a great distance through a large metallic conductor, and there be made to impart motion to electro-magnetic engines to ignite the carbon points of electric lamps, or to effect the separation of metals from their combinations. A copper rod of three inches in diameter would be capable of transmitting 1,000 horse-power a distance of say 30 miles, an amount sufficient to supply one-quarter of a million candle-power which would suffice to illuminate a moderately-sized town."

"The use of electrical power has sometimes been suggested as a substitute for steam-power, but it should be borne in mind that so long as the electric power depends upon a galvanic battery, it must be much more costly than steam-power, inasmuch as the combustible consumed in the battery is zinc, and a substance necessarily much more expensive than coal; but this question assumes a totally different aspect if in the production of the electric current a natural force is used which could not otherwise be rendered available."

THE ISTHMIAN CANAL.—We read that the construction of this canal work on both sides of Lake Nicaragua will require a total of 20 lift locks of 107 7-10 feet average, which can be distributed advantageously at proper distances apart. A tide-lock is supposed necessary on the Pacific coast, and the indentation of Brito must be made entirely smooth in order to effect a safe entrance or exit from the canal. This coast is so favored by fine weather as to render a harbor for vessels awaiting transit not necessary, but should a harbor be desired, San Juan del Sur is not five marine miles from Brito, and is a good and sufficiently commodious harbor. Commander Lull estimates that the cost of the construction of this work, allowing the usual 25% addition for contingencies, is nearly \$65,000,000. The Commissioners appointed by the President, appreciating the difficulties, delays, and uncertainties that are inseparable from great works, regard \$100,000,000 as a possible expenditure for the completion and effectual working of a ship canal having a depth of 26 feet. Should this sum be sufficient for the construction of the great work, it is plain to all who are conversant with the products of California and Oregon, and their demands from Europe and our Eastern coast, that even with a very low rate of tolls, as compared with the Suez canal, the coasting trade of the products of the United States alone, or the products of both coasts seeking markets abroad, would make an outlay of \$100,000,000 remunerative as soon as the work was constructed.

New Style Suspension Bridge.

There has been a suspension bridge just finished at Pittsburg, Pa., which the *American Manufacturer* says is unlike any other similar structure in the world, and may be briefly described as follows:

The bridge consists of three spans. The center span is 800 feet and the end spans 145 feet each—the total length from back to back of the anchorage being 1,245 feet. The roadway rises from each end, and at the center of the channel is 83 feet above low-water. The saddles on top of the towers, upon which the chains rest, are 180 feet above low-water, and the deflection of the chain is 83 feet. The floor is divided by iron hand-rails into a 21-foot wagon-way, and two six and a half-foot sidewalks. The piers are built of Baden sandstone, laid in cement. The towers consist of four columns 30 inches square, braced together by lattice-work, and are of wrought iron, except the bases of the columns. The saddles on top of the towers are of wrought iron, and are on steel rollers, to allow for changes caused by variations of temperature, etc. There are two chains, one on each side of the bridge. The links are formed of from 11 to 14 bars, 20 feet long and eight inches by two inches to eight inches by one inch in size, and are connected by six-inch pin bolts, the same bolts also connecting the links. The bridge is stiffened by means of rigid chords, which extend (above the chains), at an undeviating angle, from the towers to the center of the middle span, where they are connected by a hinge, to allow for expansion and contraction. The material used: Timber in foundations, 4,442 feet, board measure; masonry in anchor walls, 10,868 cubic yards; masonry in piers, 7,507 cubic yards; iron in foundations, 12 tons; wrought iron in superstructure, 2,084 tons; cast iron in superstructure, 52 tons; steel in superstructure, 32 tons; timber in superstructure, 810,000 feet, board measure; number of links in the chains, 1,832. The cost of the bridge was \$525,000.

SUBMARINE FRESH WATER WELLS.—M. Toselli, of Paris, to whose inventive fertility are due some of the most ingenious apparatus yet contrived for submarine engineering, proposes to utilize the fresh-water springs at the bed of the ocean for the construction of mid-sea watering stations. The apparatus is in effect a portable artesian well, and consists of a heavy bell, sunk inverted over the spring, and carrying one end of an elastic tube, the other end of which passes through a hollow buoy at the sea-level, and delivers the fresh water at a height corresponding to that of the source of the spring. M. Toselli states that when he has been exploring the bed of the sea he has noticed water bubbling up through the sand, and on one occasion, in the harbor of Marseilles, measured the temperature of a thermal spring, over which his *talpa marina* was suspended. At the exhibition that is to be in 1878, M. Toselli will erect, by share-subscription, an immense aquarium, large enough to serve for experimental illustration of the numerous and most ingenious appliances he has devised in aid of this branch of engineering science.

PROPOSED IMPROVEMENTS IN VENICE.—Among the engineering projects of "New Italy," is one of Giovanni Antonio Romano, for restoring, at least in some measure, the commercial prestige of Venice. His plan embraces an extension of the railway to the eastern extremity of the island La Giudecca, the building of moles, embankments, wharves, storehouses, yards, docks, stations for passengers and freight, and the union of the State, the Venetian Commune and the Chamber of Commerce, in joint guarantees of bonds for construction, as well as in equitable division of the revenues. He represents Venice as the most accessible port for Switzerland and Western Germany, while it might treasonably hope to compete successfully for a large part of the commerce of Eastern Germany. If proper arrangements are made for deepening the channels and keeping them clear, the double approach by Malamocco and by S. Nicolò di Lido, will make the harbor one of the most accessible as well as one of the best in the world. Commercial enterprise, combined with a judicious and liberal policy in the removal of restrictions and in furnishing facilities for trading vessels, ought to invite to such a harbor a large traffic with America, Asia, Africa and Central Europe.—*Il Politecnico*.

THE DETROIT RIVER TUNNEL.—The committee, to whom was assigned the duty of receiving and examining plans and proposals for the construction of a tunnel under the Detroit river, reports to the Detroit City Council that four classes of plans or proposals were received: 1. For tunnels excavated by the usual process of drifting. 2. For tunnels excavated wholly or in part by means of caissons. 3. For submerged tubes, placed entire or in sections. 4. For machines for excavating. After a careful examination the committee were unable to recommend as feasible any but the construction by drifting or by caissons. They believe that the method by caissons is impracticable, the great difficulty being to make water-tight connections. As to the location they express no opinion, but recommend that the first step towards the building of the tunnel be the making of careful surveys of the river and tests of its bed. They believe that an immediate commencement would be decidedly in the interest of Detroit.

STEAM ON THE CANAL.—"W. W." writes to the *Inter-Ocean* as follows: "The Illinois boatmen have solved this problem, and practically demonstrated that steam power is far superior to horse power in every respect for canal use. The propeller and barge system has superseded horse-boats, and carry grain and lumber so cheap that the railroads cannot touch it. This great saving in time and cost of transportation is accomplished by running two boats with one crew. The propeller pushes the barge, which is fastened with rigid couplings, and holds the two boats as firm as one boat. In this way there is but one break in the water, and the two, when coupled together, run steady and steer easier than the propeller alone. The propeller and barge clears from \$300 to \$500 per trip, when a horse-boat can't clear a dollar. The propeller and barge are perfectly independent. They help themselves in the canals, rivers and harbors, and the instant they are boarded proceed without looking for teams, tugs and waiting on other captains' orders. The Illinois Canal Commissioners' report of 1876 shows that nearly all the freighting is done with steam canal-boats. They also say that the propeller and barge doubles the capacity of the canal. The tolls on the Erie canal are reduced to only a half mill per 1,000 pounds per mile on all kinds of grain, while the Illinois canal-boatmen must pay two mills per 1,000 per mile on grain."

THE HOOSAC TUNNEL COAL ROUTE.—A dispatch from Scranton, under date of the 8th inst., says: "The joint committee of the Massachusetts Legislature on the Hoosac tunnel, accompanied by C. F. Young, General Manager of the Delaware and Hudson Canal Company, and a number of railroad officials, after a brief glimpse of the anthracite resources of the Lackawanna valley, left Scranton by special train for Binghamton this evening, and will proceed to Buffalo to-morrow over the Erie railway. They speak favorably of the proposed route of the Boston Hoosac tunnel and Western railway, and the prospects are that the project will be carried out at an early day. It will form a new outlet for Scranton coal to Boston and the principal cities of the Merrimack valley, and will connect with the Delaware and Hudson Canal Company's road at Schenectady, affording easy access to all its branches."

TELEGRAPHIC CABLE BETWEEN FRANCE AND ALGERS.—The President of the French republic signed a decree containing his approbation to a treaty passed between the Minister of the Interior and M. d'Erlanger for the establishment of a new telegraphic cable between Marseilles and Algiers. This cable will be placed in position before the Eastern Telegraph Company at the end of April, if the weather permits. This will be the third wire between Algiers and France; the first was laid in 1870 between Marseilles and Bone; the second between Marseilles and Algiers in 1871; the third, that which has been conceded to, will be laid between Marseilles and Bone.

A Rich Old Mill Site.

A few months ago Harrison Gray purchased the wooden shell of the old Union mill, in Gold Hill, opposite the Fountain house, for \$1,000. The mill having been dismantled and the machinery all taken away, the owners thought they were getting a good price for the rotten lumber, and probably laughed in their sleeves at Mr. Gray's greenness. The purchaser immediately put some men to work at the south end of the mill, taking up the flumes and sluices, and came upon the hole in the ground where the waste had been allowed to run when the mill was in operation. This hole had been made at this place because a tunnel was known to pass within a few feet, and the refuse, being in a liquid state, would flow off through the tunnel. The flumes had no sooner been removed than the presence of quicksilver was made apparent. Closer examination revealed the fact that a space of ground, about four by five feet, was permeated with small globules of pure quicksilver, carrying a heavy percentage of gold and silver. This ground was all dug up and sluiced, until a shaft 25 feet deep and six feet wide had been dug, when a connection was made with the tunnel, and a large deposit of quicksilver was found, in such purity that it can be raised to the surface by shovelfuls. The only preliminary work necessary is to carefully skim the surface ground and put it out of the way, when there lies revealed a genuine quicksilver and gold mine. How much of a deposit there is has not been ascertained, as the parties at work there are very reticent, but it is known that between \$8,000 and \$10,000 has already been taken out and sold. A great part of the amalgam carries a higher percentage of gold than of silver, because the mill was running in the early days of mining on the Comstock, when the ores were worked for the gold alone and the silver was allowed to flow off. There is no doubt but that the deposit will be found to continue to the bedrock, which is probably 50 feet deeper than has yet been attained in the tunnel. For about three months there were five men employed there, and the yield was about 60 pounds of amalgam per day, but since connection has been made with the tunnel only two men have been employed, who take out about 40 pounds of quicksilver per day on an average. Parties who are anxious to get old mill sites off their hands will probably be more careful in future and examine them well before disposing of them.—*Virginia Chronicle*.

The Blue Gravel Country.

Last Monday, in company with a friend, we visited the new mines in the neighborhood of Nelson Point. Coming back over the Middle Fork bridge, the trail leads down the river a half mile to the Blue Gravel company's new works. The present company purchased the claim from the original locators last year, and, thoroughly satisfied with the prospects developed by the first tunnel, have since been engaged fitting up the mine. They will do their work from a large shaft, 80 feet in depth, and considerably above the high water-mark of the river. A ditch dug from Willow creek furnishes the necessary power to run a "hurdy wheel," which does the pumping and hoisting. Between 300 and 400 feet above the shaft-house a capacious reservoir has been built, and from this the iron pipe conveys the water to the wheel, the pressure being 180 feet. An inch nozzle is used on the pipe, and with this pressure the little 14-foot wheel "hums like a top." The water is pumped from the bottom of the shaft and empties into a tunnel, which carries it out into the river. It may be well to state that the bottom of the blue-gravel channel is several feet lower than the present river channel, which makes it necessary to work through a shaft. The pump works splendidly, and will clear the mine, at present, in 15 minutes, of the water which comes in a day. The dirt is hoisted into cars, which run on to the "cage," and for a smooth working arrangement in the hoisting line, we never remember to have seen this one equaled. One man is all that is required to manage the machinery and attend to the cars. The touch of a lever sends the cage and car down the shaft, and at the bottom the car is run to the drift for its load and back to the cage. Another touch of the lever, and it comes rapidly up the shaft, stopping just at the right place to join the track to the outside track, and the car is pushed to the dump, which is only a few feet away. By using two cars and two men above, we are assured that the machinery will keep 100 men at work in the mine below. The car brings up 2,500 pounds of gravel at a load. The wash-flume extends down the river from the shaft-house, and a capacious reservoir supplies the water. A waste-flume from the upper reservoir keeps the lower one full. Everything about the works indicates that the company are making arrangements "to stay," and intend to be thoroughly prepared before going into the drifts. The plans were made by Mr. John Porter, and the work has been entirely under his management. He is surely a mechanic, and a good one, and the machinery, although new, runs as regularly and smoothly as a clock. The whole cost of the improvements up to the present time will not exceed \$6,000. Work was to commence in the drifts on Tuesday last, and the force of miners will probably be increased as fast as room is made for them below. We have often spoken of the rich prospects of this mine, and have every faith that the company will prove it to be one of the best in the northern part of the State.

After a couple of hours pleasantly spent in looking over this mine and improvements, we crossed the hill to the adjoining claim, the Franklin. Here we found the Superintendent, Mr. Knapp, who, with an extra man or two, is keeping the water pumped from the shaft, and awaiting orders from headquarters below. The Franklin shaft is now down about 80 feet in the lava cap which covers the blue gravel. They expect to have to sink about 60 feet further to find bedrock. A splendid steam engine furnishes them with pumping and hoisting power, and Mr. Knapp, who is a practical engineer, manages it with the ease which an old-line stage driver would a "mustang." The water raises about eight feet an hour in the shaft when the pump is not running. Everything looks like business around the Franklin works. Several hundred cords of wood are piled up and ready. Mr. Laoy, of San Francisco, one of the principal owners, is expected every day, and the work of sinking will soon commence. There is little doubt but that the gravel will be found, and the company have decidedly good prospects for a very valuable mine. We have an abiding faith in this section of our country, and predict that the two companies now at work will, during the coming summer, demonstrate that the blue-gravel strike at Nelson is the most important gravel discovery ever made in Plumas.—*Plumas National*.

THE SESPE OIL REGION.—Captain Westley Roberts, Superintendent of the Los Angeles and other oil claims located on the Little Sespe in town on Tuesday, and reports everything working smoothly in that section. Work on the road to these claims has been rapidly pushed, and a good wagon road is now completed to the Los Angeles claim, to which the company expect soon to obtain a patent. Several shafts have been sunk on this claim, and a good quality of oil struck. A tunnel is now being run into the side of a mountain, which already yields between two and three barrels of oil per day, of a fair grade. There is now on the ground a tank with a capacity of 500 barrels, and 750 feet of pipe have been put down. We are informed that a complete outfit of drilling apparatus has been ordered by this company at the East, and is now on the way out. The outlook for the speedy development of valuable oil territory in the Sespe region is certainly encouraging.—*Ventura Free Press*.

The Chloriders.

What the early miner, with his pan and rocker, seeking after gold in the shallow gulches or crevices of bedrock laid bare by rushing waters, was to the early days of life in the California mines, so is the chlorider of eastern Nevada to this section, with this possible difference, that the gold was easier to find and required less labor in the seeking than the bright silver concealed and distributed through veins of ore. But there is the same independence of calling, a throwing off of the yoke of daily wage, an element of glorious uncertainty that knows not its ultimate reward, but is ever cheered by seductive hope and a chance to do better than the servile crowd who prefer four dollars per diem and a surety of a pay-day monthly. The chlorider is not at his best, in Kureka, as the character of our ores do not promise great gains without steady and well-directed development, and it takes capital as well as labor to prosecute work to any extent. Still, Prospect mountain furnishes a limited field for the independent miner, and numberless locations are worked, and the accumulation of ore sold to the different smelting furnaces by companies of three or four sturdy fellows who rely on their superior knowledge and capacity for selecting and developing these small properties, and the consequent larger returns for their labor.

There is one district in the county where the chloriders exist *pure et simple*. We refer to Mineral Hill. The deposits in that district are in a limestone formation and occur in nests or cavities in the rock. Outside of the first discovery, which was the largest ever found on the hill, and which paid enormously for a time, there has never been any large deposits met with, although the hill is permeated and honey-combed with small streaks and cavities, containing, when found, masses of decomposed ores and chlorides that assay away up in the hundreds. Here is the chloriders' paradise. Whether he holds ground of his own, or on the other hand, as is the custom to a large extent, leases it for the consideration of a percentage of the net returns to the owners thereof, the process is the same. All that is necessary is the presence or a thin clay seam or a mere stain in the hard limestone to encourage these hardy miners in their labors, for they know that by following it through the rock that it will eventually widen out into a cave that is sure to contain more or less ore, and nine cases out of ten the ore is of so high a grade that even a ton of it will repay for the labor expended. It does not take much ore at from \$1,000 to \$2,000 a ton to pay wages to a couple of men for a year's work, and if, as is sometimes the case, there are eight or ten tons in the deposit, small fortunes are realized. The excitement and uncertainty of this branch of mining is very seductive, but it is a fact that in every instance where it has been followed perseveringly the reward has been greater than could have been realized in any field that unaided muscle could have entered. There are some 75 men engaged in the work at the hill, and we venture to say that a more respectable or intelligent set of miners cannot be found in any part of the world.—*Eureka Sentinel*.

Resources of Eastern Oregon

That eastern Oregon is gradually looming up as one of the best fields in the country for the investment of capital cannot be questioned. Her mines, her soil, the vast extent of rich grazing lands, the forests of fine timber in many sections, with unequalled water-power facilities all combined to make this country one of the most desirable for profitable labor that the sun ever shone upon. In the natural course of events it must be impossible for such a region to remain occupied by a sparse population for any very great length of time. When we reflect upon the fact that in the East and West the army of unemployed men is numbered by hundreds of thousands, and that the number who plod along from year to year and make but a bare livelihood, is still greater, we find no element of comfort in contemplating the existence of that shortsighted policy, dictated by legislative parsimony which is instrumental in keeping these vast unproductive fields in the condition they are at present. With even limited means and a small stake, men of energy could find locations in eastern Oregon and Idaho that with moderate diligence and toil, would, in a few years, place them beyond the reach of want. But the leading source of wealth in that section of the country to which we designed to call attention at the present time is undoubtedly to be found in its magnificent mineral resources which present a most promising and inviting field for the capitalist. With such mines as the Monumental, the Virtue, and those at Connor creek and other parts of eastern Oregon, there is a foundation from which increased wealth, population and prosperity must be an established certainty, if a system of liberal development be pursued. We regard the outlook for that section of the country as most promising. Many of the gentlemen who are interested in these mines seem to be made up of the right kind of material and with their go-ahead instincts the country will soon take a fresh stride forward. The mining interests of eastern Oregon are certainly looking up, and we congratulate all interested upon the near approach of more decided prosperity.—*Owyhee Avalanche*.

USEFUL INFORMATION.

Market for Petroleum.

The fact that the Eastern petroleum producers are making a market for their oil in the East Indies, should remind our oil men that the East Indian demand is theirs by proximity. We find the following in the *Iron Age*: "The steamer *Spartan*, which sailed from New York recently, for various ports in Java, is said to be the first steamer dispatched from New York for the East Indies by way of the Suez canal. The venture is not only novel as to the route, but is otherwise a novelty. Her cargo is nearly 400,000 gallons of refined petroleum; the first cargo exclusively of oil ever loaded in an ocean steamship. It is packed in 10-gallon cases, enclosed in wood. The steamer will stop at Gibraltar and Port Said for coal, and is expected to complete her voyage in 40 or 45 days. There has recently sprung up a lively demand for petroleum in Java. This caused large shipments to be made during January and February in sailing vessels that will require four or five months to complete the voyage around the Cape of Good Hope. The cost of the oil was at that time 35 cents a gallon, and with the freight and insurance it will be landed in Java at 39 to 40 cents. Since then petroleum has declined. The cargo of the *Spartan* cost but 23 cents a gallon, and, although the freight by steamer is much more than by sailing vessel, it can be landed in Java for 29 or 30 cents a gallon. Thus the cost is 10 cents cheaper than the cargoes previously shipped, whilst, if all goes well, the owners of the steamer's cargo expect it to arrive out before the others, and thus reap a large profit. By May 1st the steamer ought to be at Javan ports; but the sailing vessels cannot get there before the middle or close of the month. These facts lend additional interest to the voyage."

TO RENDER PLASTER-CASTS WATER-PROOF.—Mr. R. Jacobsen gives in a German paper, the following method for preparing gypsum molds so that they will permit being washed: "A neutral soap of stearic acid and caustic soda is prepared and dissolved in about ten times its weight of hot water. The molds or objects are either coated with, or immersed in this solution. By this procedure the color or the object is not affected, it is rendered impervious to moisture, and permits the object to be washed, even with lukewarm soap water; since stearate of potassium is only soluble in hot water. Soap water is entirely superfluous for washing gypsum casts; warm water is all that is requisite. Ordinarily, molds, etc., are cleaned of dust and dirt by means of soap water. This removes the dirt, but leaves, in its place, a film of soap, which most readily collects and retains dust. This same difficulty is presented by gypsum that has been impregnated with a solution of alum and stearine. A coating made with a solution of stearate of alumina in benzole behaves in a similar manner. The gypsum can also be made impermeable to water by saturating it with a solution of oleic acid in benzine; this should be but slightly colored and oxidized. This solution is to be applied to the object when cold, and in such quantity as to completely saturate the gypsum. These objects are not to be cleaned with soap water, since this would take up the oleic acid, but should be wiped with a cloth, moistened with the acid. The first described method gives the best results, and is especially to be recommended in voluminous castings."

NEW USES FOR ROCK-CRYSTAL.—In a recent note to the Berlin Chemical Society, says the *Journal of Chemistry*, Herr Stein proposes some new applications of this substance. It is very suitable for balance beams and scales. These should be very light. Now rock-crystal has a sp. gr. of 2.65, and so it is nearly as light as aluminum (2.61). But its superiority to aluminum and other substances lies in its not being attacked either by acids or bases, or by air and its moisture at ordinary temperature. It is rigid, and does not bend with ordinary weighting; the limit of elasticity is near the limit of fracture. Again, divided circular discs for use in telescopes, theodolites, quadrants, and the like, might be made of rock-crystal, which is very unalterable. Rock-crystal may also be used to make an invariable normal thermometer (for which a prize has been offered by a Prussian society). The crystal is bored out and polished, and the open end bored wider for the mercury reservoir; in the outer end is inserted an airtight conical stopper of rock-crystal. By means of a piece of iron in this stopper it is moved with a magnet under the air pump when the thermometer is being filled. In free air, the thermometer remains closed by the air pressure itself. Such an instrument does not alter either in length or width.

EFFECT OF SUNLIGHT ON FLOUR.—It is maintained, says the *Millstone*, that the inferior quality of certain kinds of wheat and rye flour is frequently due to the action of sunlight on the flour; even when in bags or barrels the gluten experiences a change similar to that occasioned by heating in the mill. The tendency thus imparted to it, to become lumpy, and to form dough without toughness, is similar to that of moist grain, or of flour when it is too fresh, or made from grain ground too early, or when adulterated with cheaper barley meal. Such flour can be improved by keeping some weeks.

CLEANING WATCHES.—A perfect cleaning of the pieces of a watch after repairing is an absolute necessity, not only for preserving the parts, but also for preventing the rapid deterioration of the oil, which is the inevitable result of bad cleaning. Several watchmakers have noticed that the oil is preserved intact longer after washing with soap, if well done, than after cleaning with benzines, etc., though in some instances, it may be that the latter process was not properly performed. However, the following is the method adopted for some years by M. A. Bertrand: Dissolve in about a quart of rain-water a piece of Marseilles soap, about one and a half inch square, pared very fine, and add a piece of black soap the size of a hazel nut. Boil, filter through a linen rag, and bottle the liquid. When required for use pour a little into a capsule and place the parts (excepting those fixed with gumlac) in it, boil it slightly, and having put back the liquid in the bottle, pass the parts through rain-water, slightly boiling, and then plunge them in alcohol. On taking them out, dry them with a linen rag. By this means the pieces are much better cleaned than they would be if benzines were used. Should the polished wheels turn a little brown, it may easily be made to disappear by passing lightly over the stained portion, and without touching the steel, a pencil-brush dipped in water mixed with oxalic acid (oxalate of potash, commonly called salts of sorrel), and dipping in water and alcohol, if necessary, it may be touched up with a dry chamois leather.—*Revue Chronometrique*.

SOLVENTS OF INDIA RUBBER.—The following upon the solvents of caoutchouc or india-rubber is very valuable: Of the solvents of caoutchouc, its distillate, caoutchoucine may be placed at the head of the list; the others best known are pure chloroform, carbon disulphide, rosin, oil and coal naphtha, rectified oils of turpentine, gutta percha, tar, lavender, sassafras, ootene, rosemary, amber, ambereupion, terebene, benzine— $C_{10}H_8$ —hydrochlorate of terebene, benzole— $C_{10}H_8$. Anhydrous oil of turpentine dissolves 49% of caoutchouc. A mixture of 6% to 8% of absolute alcohol and 100 of carbon disulphide is an excellent solvent. Sulphuric ether, which alone is but a poor solvent, dissolves rather more if about 5% of anhydrous alcohol be added thereto. Hot alcohol dissolves out about 4.712% of a soft resin. It is sparingly soluble in hot fused oil—hydrate of amyl $C_{10}H_{21}HO$; readily at a gentle heat in melted hog's lard or in very hot whale's oil. After swelling up in oil of turpentine or in naphtha it is soluble in hot linseed oil.

MAKING WOOD STRONGER.—Soaking wood at 80° to 100° C. in linseed oil for two or three days increases its resistance to fracture. Throwing the pieces to be treated into a kettle, in which linseed oil is being boiled, and leaving them in it for a few days, is better still. This is a good remedy when the wood has to be exposed to moisture; when it is to be kept in a dry place, it is better still to soak it in a boiling solution of glue. This penetrating the pores, makes it stronger still.

GOOD HEALTH.

Sprains.

EDITORS PRESS.—An extract from *Hall's Journal of Health*, which appears in your paper on the subject of sprains and how to treat this ailment, brings out this correspondence from one who is not a graduated M. D., but has from his youth given considerable attention to the medical and healing art, and would like to speak of sprains and some other matters pertaining to health, while your correspondent believes that the time has arrived to freely discuss the subjects herein presented. And the writer thinks that he may truly be called a "natural physician," who is the parent to nine very healthy children, and in his own house he has in general been the family doctor. The method of treating sprains, as published, is some respects is well; but I would not advise the application of a stream of cold water to the affected parts, because cold applications often prove very injudicious and injurious to the wounded limb.

In bad cases of sprain about the ankle joints, where dead blood immediately settles, and, of course, swellings inevitable, the part becomes heated and this useless blood must somehow be removed. Hence we advise the patient to keep quiet, remove this collection, guard against fever in the parts, and then the patient is soon out of danger. An application of cold water may reduce a swelling, or relieve pain momentarily, but a reaction usually happens where the cold stimulants are thus applied. Soon after treatment blood centers in those parts which become overheated and dry, the tendons are stretched to their utmost capacity, while fevers and excruciating pains follow.

The patient does not recover until the swellings and pains are removed. Our practice of bathing the parts in water heated to 112° is highly beneficial, and as soon as removed from the bath wipe over, manipulate and dry quick. Then cover with flannel or other bandages, and repeat the process at least three times each day. The cold shower produces heat, while the warm bath and manipulation tends to remove the fever and pains.

Take leaves from the green bark or 'striped

maple' bush, or liberal slices of salt, fat pork, and bind on over the region of pain and swelling. Either application is highly recommended to sweat out the secretions and fever; it removes hard swellings and gathering or pustulation, if applied in season.

After the part has been immersed or showered, either with cold or hot water, it is more beneficial to dry off by the hand movement, passing down or outward. This will restore severe cases to strength and health.

S. W. JEWETT.

Bakersfield, Cal., April 17th, 1877.

HEALTH IMPROVEMENTS IN GREAT CITIES.—On this subject Dr. Richardson, F. R. S., has recently delivered a lecture at the London Institution, in which he gave further illustration of the high views he entertains in regard to house sanitation. He considers that for purposes of health the houses in England require to be rebuilt or remodeled, from Land's End to Hebrides. Dr. Richardson entered into the history of ventilation from the time of Stephen Hales, in 1733, to the present day, and explained the different discoveries that had been made in the various branches of science bearing on the health of towns, all modes of construction were of necessity imperfect. He called attention to the influence of water, dampness, light and darkness, etc. The effects of light deserve special notice. Having got from India some poison of the cobra, on ivory points, he discovered that on some of those which had been exposed to the light, in a glass bottle, the poison had become inert, while on others that had been wrapped in paper, in the same bottle, the poison retained all its deadly activity. He hence argued that, if sunlight exercised such power on the poison of the cobra, it might by analogy destroy the poison of small-pox, scarlet fever and typhoid. He considered that pure air and water, freedom from damp, pure daylight and equal temperature were essential.

DRINK AND DISEASE.—A recent number of the *Lancet* gives some curious calculations which have been made of the proportional amount devoted by the workmen of Birmingham to the support respectively of their liquor saloons and of their hospitals. The figures bear something like the ratio of 30 to one. Fifteen thousand dollars is contributed annually by them to the medical institutions of the town, and \$450,000 is spent in drink. The *Lancet* further asks: "What proportion does the contribution of the workmen bear to the total expenses of the hospitals? and what proportion of the work of these medical institutions is occasioned by the drink on which they spend so much?" Commenting on the state of the case, the writer says: "We remove every obstacle to as free a consumption of liquor as is consistent with the maintenance of equilibrium, and then, with a benevolent appropriateness, we provide hospitals in which the consequences of drink may be recovered from, or ameliorated." The corrective suggested for this state of affairs is, that the drink sold within a certain area should be so taxed as to defray the expenses of skilled treatment for those whom drink has incapacitated for their work.

DOES MILK CURDLE IN THE STOMACH?—The moment milk enters the human stomach the digestive fluids change it into curd. The cheesy part is separated from the whey, or watery part. We often hear mothers say when their infant vomits up curd, that their milk does not agree with it, that its stomach is sour and curdles the milk, and the curd is very hard. The truth is that the milk in the stomach always curdles before it digests. If it did not curdle it would prove that the stomach was weak. Those infants who are fed at regular intervals are less apt to overfeed than those who are fed at irregular periods. We have found that infants nursed at intervals of two hours are much more apt to suffer from indigestion. Some mothers may ask, why is human milk more digestible than cow's? The principal reasons are two: first, the amount of curd is greater in cow's milk; and second, the curd is harder, i. e., the casein from human milk is more porous, and is on this account more easily dissolved and digested.—*Herald of Health*.

FRUIT FOR A SUMMER DIET.—The *Herald of Health* makes the following timely remarks: "Now that the warm season of the year is at hand, it may be worth while to call the attention of our readers to the fact that, if they wish to keep well, they should add as much fruit to their daily food as possible. It will save doctors' bills, and, what is more important, much illness. Of course there are many who cannot, or think they cannot, eat fruit. The cause often is a spoiled stomach. In such cases it takes time and care to habituate this organ to the change, and sometimes it cannot be done at all. Leaving out such cases, we advise the liberal use of fruit from this time on, wherever it can be obtained."

PRECAUTIONS IN SCARLET FEVER.—The funerals of those who die of infectious diseases should be strictly private. Disinfect the clothes, bedding and room by sprinkling them with a solution of commercial carbolic acid, two parts to one hundred parts of water, or other disinfectants may be used in a similar way. Let the door be closed for several days. Sulphur may be burned in the room sufficiently to fill it with sulphur four times a day. Continue this for four or more days. Then strip off the paper, scrape the walls and ceiling, and whitewash them. Scrub the woodwork with strong soda and a solution of carbolic acid.

OLD NEVADANS.—We have received a card announcing the second re-union of "Old Nevadans," at Badger's park, Oakland, on Saturday, June 9th. The occasion will doubtless be very enjoyable to all of old Nevada memory. Full particulars concerning the re-union can be gained on application to the Secretary, C. C. Leavitt, at the Custom House, San Francisco, or P. O. box 987, San Francisco.

WM. M. DONNELL, an old resident of Kern county and one of the discoverers of the Big Blue mine, died in Inyo county last week. At the time of his death he was constructing the Minnietta mill; he met with an accident some time since by the upsetting of an amalgamating pan, and received internal injuries from which he died. He was at one time a merchant in Tuolumne county.

A TEMPERANCE organization has been formed in Washington under the name of "Mrs. Rutherford B. Hayes Temperance Society." Resolutions were adopted indorsing the sentiments of Mrs. Hayes in regard to the use of intoxicating liquors at State dinners, and similar occasions.

FRANK LESLIE and wife and a party of artists and literary men have arrived in San Francisco. It is the intention to remain in this city and State for some time to photograph, write up and sketch everything of note. They are staying at the Palace.

Blasting in Mines.

There is scarcely a week passes that we do not hear of accidents by blasting, in which loss of life occurs. In nine cases out of ten these accidents are due to carelessness; the men apparently forgetting that they are dealing with a deadly explosive. In tamping, the greatest care should be taken, as it is then that explosions most frequently occur.

With Black Powder.

Let the charge be put into the hole; not all at once, but whilst it is being done settle it down two or three times with the swabstick, and when all in, ram it well down with the same tool—not with the iron ramming bar—and cover it tightly and firmly with a piece of dry clay. This done, at once dip the end of the swabstick in water, or better still into the wet sludge that has been made in the process of boring, and with it free the sides of the hole from the dust of the powder, which must of necessity have adhered to them in pouring the charge, and which if not removed will be likely, by a spark from the ramming bar, to carry fire. Then wipe out the hole well with the wet swabstick.

Having done this, put in a large layer of fine, properly prepared tamping, and swiftly and carefully settle it down and "floor" it with the ramming bar alone, using no hammer for the first layer.

A large layer should be put in, because if the first layer be a small one, it will be more liable to be forced down by the ramming bar and disturb the powder; settle down the first layer of tamping in this way, and then, with impunity, the hammer may be used, taking care at the same time to keep the ramming bar free from the safety fuse. It is more important than many suppose that proper material for tamping should be used.

In Europe when working in hard, fiery ground, careful workmen carry tamping with them from home daily, so as to prevent accident. There seems to be a general idea that tamping needs to be driven with great force with the hammer, so that the mallet is sometimes used; but this has been fatally proved as not necessary, for if the hole be judiciously placed, even the hammer, generally speaking, need scarcely be used. On the first layer of tamping being hammered down, explosions frequently occur, and such accidents are generally fatal.

Thus far we have spoken of common black powder; but as Giant powder is used in the mines on this coast to a great extent it is necessary to refer to that also. In charging the hole with

Giant Powder.

Cut the cartridge into sections two or three inches long, and ram each section well home with a wooden tamping bar. Cut the end of the fuse square, push the cap on it until it reaches the fulminate, and then with a pair of nippers press the edge of the cap into the fuse, and in wet holes rub some grease or wax around the cap to make the same air and water-tight in the fuse. To insure a perfect blast, the cap must be squeezed tight to the fuse, for, if loosely put on, the extension will not be complete. Push the fuse, with the cap attached, down the hole until the latter rests on the powder; then put about one inch of loose powder down the hole and press lightly around the cap, so that the cap and not the fuse is imbedded in the powder. Then fill the hole with water, or sand, or clay, or use no tamping at all, as desirable; or a priming cartridge may be used, which means about one inch of cartridge, smaller in diameter than the bore hole, into which the cap, with the fuse attached, is inserted, the whole tied together with a string, and then let the priming cartridge down the hole until it rests in the powder; when loose powder is used, put down small quantities at a time and ram it well home, and use a tin tube with a funnel mouth, to prevent the powder from adhering to the bore-hole. It is of the greatest importance that only the cap, but never part of the fuse, should be on the powder, as the burning of the fuse ignites the powder and burns all up above the cap, before the explosion takes place. From the great strength of this powder, excellent execution is done without tamping it, for certain kinds of work. Experience shows, however, that when well tamped much more work is done, the amount of power gained being in proportion to the excellence of the tamping. The first four or five inches should be tamped lightly, but with the balance no more than ordinary care need be taken.

Should the fuse fail and a shot not explode, remove the tamping to within four or six inches of the powder, put in a heavy primer, and its explosion will set off the main shot. This item should be properly borne in mind and it will prevent many accidents. On no account ever try to pick out a shot of Giant powder, as it is always attended with danger. The No. 2 Giant, used for bank blasting, coal mines, medium hard rock, etc., is charged the same way as above, with the exception that its explosive properties are weakened when brought in contact with water, therefore greater care should be observed in charging wet holes. However, in wet holes a primer of No. 1 powder will always insure a blast. Another caution which should be im-

pressed on miners, is that they should never, under any circumstances, attempt to pick out a charge of frozen Giant powder from a drill-hole, as it is highly dangerous. If these little matters are well attended to and ordinary care taken, there is no fear of explosion and loss of life; and it seems strange that the miners themselves should be as careless as they are, when their own lives are at stake as well as the property of others. Of course, accidents will sometimes occur in spite of all care; but their number can be materially reduced by proper precautionary measures.

Ancient River Channels.

Theory of their Formation.

In our last issue we gave the result of an interview with Mr. H. S. Jacobs, who has lately made an extended trip in the gravel mining regions of California. Regarding the manner in which the channels of the buried rivers were formed, as well as the character of the streams themselves, and the agencies most active in filling them up, Mr. Jacobs entertains opinions not altogether in accordance with the more commonly accepted theories. The channels of these old rivers, he believes, were eroded by fluvial and not by glacial action. These rivers, though of great magnitude and running swiftly, were not remarkable for their length. They had their sources, like the modern river system, in the valley of the Sacramento, and did not head in the far north, traversing some thousands of miles in their course, as some writers on this subject hold; their theory being that the enormous boulders formed in the channels of these buried rivers could have been brought down only by a vast, swift rushing volume of water, and that they must have come a great distance to have been rounded and polished as we now find them. In the great width of the water-worn bedrock, as disclosed by hydraulic and drift operations, we find, as these theorists alleged, further evidence of the immensity of these pliocene rivers. But as this might have been produced by these streams shifting their channels, it does not conclusively prove for them an extraordinary width.

How the Boulders and Gravel were Produced.

This entire country was once submerged by the sea, as is shown by the marine fossils scattered over it. The volcanic action that produced the Sierra Nevada gradually raised the whole country above the surface of the ocean, after which the ancient rivers began to form, wearing out in course of time their present channels. After these were eroded, volcanic and other dynamic movements ensued, crushing the quartz veins that thickly ribbed the Sierra to its top and grinding them into fragments, accumulated along the mountain sides great masses of this gold-bearing detritus. Some of these convulsions, occurring periodically and with great violence, so tilted up the westerly slope of the mountains that immense quantities of these boulders and this auriferous gravel, rendered smooth and sound by previous commotions, were suddenly swept into the old river channels running not far below, filling them up and forcing the water further over towards the west, where it formed for itself a new channel. Through the repetition of this process the several old river beds, forming an irregular and somewhat complicated system, as we now find them, were produced.

The Outpourings of the Volcanoes.

In the meantime, the volcanoes along the crest of the Sierra for a distance of several hundred miles, belched forth at intervals showers of ashes, which, falling into the torrents along the mountain sides, were carried down and deposited in the channels of the rivers, already partially filled up with gravel, clay and boulders, forming with the alumina and magnesia brought down the masses of pipe clay with which the auriferous material is interstratified or overlaid. Following these outpourings of ashes and this flow of other matter, came floods of lava and conglomerate, which, running down the mountain sides, covered up, above a certain line of elevation, both the pipe clay and the entire country, in many places to a great depth.

Other Examples.

The alumina and magnesia, being the lightest materials in the interior of the earth, would naturally be on top of the boiling mass that filled the volcanic craters, and, hence, the first to flow out. Of this fact, Mr. Jacobs, during a visit to the Sandwich islands, learned from an eye-witness a striking confirmation, which occurred during an eruption of Mauna Loa, in the island of Hawaii, where a stream of this material, forcing an orifice through the lip of the crater, shot out like the arch of a rainbow, and, passing over a number of persons without injuring them, fell upon others further down the mountain side with fatal effect. Mr. Jacobs has examined the gold-bearing gravel deposits of Australia and believes them to be coincident in chronology and to have been formed by the same agencies as were those of California.

It is expected that the Suto tunnel will reach the Comstock lode some time in February next.

Early History of the Eastern Slope—No. 5.

The Pioneer Officials of Nevada—James W. Nye.

The following reminiscences, connected with the history of the early officials of Nevada, Territorial and State, may not be without interest at the present day, as some of these personages have since acted a prominent part in public affairs, while others have earned for themselves a national reputation in the walks of literature, a good many of their number having also passed away.

James W. Nye, first Governor of the Territory, and one of the two Senators first chosen to represent the State in Congress, was a native of the State of New York, where he had always lived until he came to this coast. He was a lawyer by profession, and a politician by every instinct and impulse of his nature. At the bar he stood well as an advocate, more especially in criminal cases, in the conducting of which he was remarkably successful, having been engaged in many legal contests with the ablest criminal lawyers of the State. Numerous anecdotes, illustrative of his astuteness in this branch of practice, are related of him, some of these being equal to the best stories told of the American bar. He could be forcible, humorous or pathetic, as occasion required, his style of oratory, both on the stump and before a jury, being peculiarly happy. He never lost his entire self-control, nor suffered his temper to become in the least ruffled. However much his ire might be excited, he never seemed to be angry. He had a way of illustrating his subject with familiar allusions and anecdotes, often quaint and homely, of which he had always a full supply, and possessed the faculty of relating in a manner that never failed of appreciation, whether uttered before the elite of San Francisco, or the rough miners and bordermen of Nevada.

Nye was appointed to the position of Governor by President Lincoln, with whom he was personally intimate. He was a man of powerful build, bold in speech, and brave as a lion—qualities that Lincoln, though himself a quiet and peace-loving man, greatly admired in others.

About the time of the breaking out of the war, Nye, happening to be in Washington, met at one of the leading hotels there a party of Southerners, one of whom, in the course of a general conversation on politics, made some remarks exceedingly disparaging to the courage of the North. Without making any reply, and almost before the words were out of the fellow's mouth, Nye, who had the arm of a Hercules, drew off and struck him such a blow as knocked him senseless, and, for a time, threatened to prove fatal. The man was surrounded by his friends, all, no doubt, well armed, but they prudently refrained from attacking his assailant, who was not only unarmed, but without an acquaintance in the crowd.

This incident coming to the ears of the President is believed to have had something to do with the appointment of a Governor for the new Territory, known to be full of sympathizers with the Southern cause, many of them open and defiant secessionists and all requiring to be sternly dealt with in order to prevent their precipitating a conflict in a country not only without the presence of United States troops, but enjoying scarcely more than the form of a local government. As subsequent events proved, no better choice for the position could have been made, the spirit of disloyalty, before rampant, having been effectually repressed and the affairs of the new Territory well administered by Mr. Lincoln's appointee. Not only so, but Governor Nye was efficiently active throughout the whole period of the war, arousing and uniting the people by those stirring and eloquent appeals, and those lofty outbursts of patriotism, that, being continued after he took his seat in the Senate, gained for him the appellation of the "Gray Eagle from Nevada;" distinguished members of that body having been known to remark that one of Nye's speeches in the Senate was worth a regiment in the field.

Having represented the State for two terms in the Senate, this able and big-hearted man withdrew from public life, and, going East, spent thereafter most of his time in Washington, until about the year 1875, when a painful malady, affecting both his physical and mental health, compelled him to make his home with an only child, a daughter living near New York. Softening of the brain having soon after supervened, he was placed for a time in an institution especially designed for the treatment of this class of disorders. Experiencing no permanent relief he was taken again to his home, where he remained, tenderly cared for until the early part of the present year, when, at the age of about 60 years, his spirit was, by a peaceful and painless dissolution, released from a body that could no longer entertain it well. With the exception of Baker, the demise of scarcely any public man on this coast has been, by the intelligent masses, more deplored than that of Nye; his talents, intelligence and patriotism, his genial disposition and fine social qualities having gained for him friends and admirers amongst all classes. Thousands, both in California and Nevada, have heard of his death with regret, deepened into sorrow, because of the clouded condition of his brilliant intellect before the close of his earthly career.

That Curious Ore from Arizona.

In a recent issue we mentioned the receipt from a correspondent in Arizona, of some curious ore, which attracted considerable attention there, both from its richness and mineralogical peculiarities. It was micaceous iron ore, containing both gold and silver. As there is a remarkable combination of metals not heretofore found, we turned some of the specimens over to Mr. Henry G. Hanks, the chemist and assayer in this city, knowing that his well known zeal in this direction would cause him to make a thorough examination and analysis of this curious ore. Mr. Hanks thought at first that it was a new mineral, but the microscope has proven differently, as the following letter from Mr. Hanks will explain:

EDITHS PRESS:—The sample of silver ore you placed in my hands for examination is identical with a specimen sent to me from Arizona, by Winslow J. Howard, of Prescott, who, in a letter describing the location and source of the interesting mineral, desired me to give it a thorough examination with a view to determine, if possible, the source of the silver, which it was found to contain in considerable quantities.

No mineralogist, in examining this mineral, would suspect the presence of silver in it, yet the assayers of Arizona—where already have congregated some of the best assayers on the Pacific coast—have united in pronouncing it rich in silver. The following extract from the *Arizona Miner* of February 24th, gives an idea of the mine in which the mineral is found and also the result of the assays referred to:

"The Sumner is better known to the public as the plumbago, stove-polish or micaceous iron mine, than by its proper name, and is situated about a mile south of the Senator gold mine, of S. G. Fredericks & Co., and three-fourths of a mile east of the Davis mine, 15 miles south of Prescott, on the very head of the east fork of the Hassayampa. Messrs. Demoché & Bigelow have been working on the mine for two months past, and have run an open cut into the vein, to cross-cut it at right angles, 50 odd feet in length; the last 26 feet being in the vein, five feet wide and 24 feet deep, and they have not yet reached the hanging wall of the ledge. The whole of the vein matter is permeated with streaks and threads of mineral, all carrying more or less gold and silver, which all run into one well-defined pay streak, which is encased in soft, green soap-stone, and varies in thickness from the surface to the bottom of the cut mentioned from two to 11 inches, the thickest portion of the ore being the richest.

"The following assays are from average samples of the ore as assorted on the dump, calculated per ton: No. 1. Silver, \$296.57; traces of gold. No. 2. Silver, \$122.51; gold, \$1.25—total, \$123.76. No. 3. Silver, \$72.90; gold, \$5.02—total, \$99.27. No. 4. Silver, \$43.98; no gold. No. 5. Silver, \$4.70. No. 6. Silver, \$3.14.

"The above assays were from Mr. Blake, the Nos. 5 and 6 being ore taken from the threads mentioned outside of the pay streak, and the four first from the ore stacked up for reduction, as are the two following by Mr. Kelley: No. 1. Silver, \$113.13. No. 2. Silver, \$181.

"A choice lot of ore was sent to the Pinal company's works at Walnut Grove, from which Mr. Geo. T. Hogle made an assay, which yielded in silver, \$2,252; gold, \$25; total, \$2,277, which is the highest we have heard of from this very peculiar ore.

We are informed that Mr. Kelley has made tests of the ore for the purpose of ascertaining the proper method of working, and has reported that it is not milling ore—a fact rather discouraging to the mine owners, for though the average value of the assays would leave a margin if it could be worked at the Senator or Aztlan mills, near the mine, it will hardly stand transportation 30 miles to the Agua Fria smelting works, and the charge of \$75 per ton for smelting. Specimens of the ore have been sent to San Francisco for analysis."

My first step on receiving the ore was to verify the silver determination of the Arizona assays. The result of my assay from a carefully prepared average showed the presence of 84 ounces to the ton of 2,000 pounds.

A chemical and physical examination shows the mineral to be the variety of hematite known as micaceous iron. This mineral containing silver is, as far as I am informed, unknown to science. A chemical analysis would, no doubt, warrant the announcement of a new mineral species; and I will not deny that I selected the name "Arizonaite" from many others as being both appropriate and euphonious, should the mineral prove to be new; but a microscopic examination showed me at once the source of the silver, and that instead of being a new mineral species, it was only a mechanical mixture of two well known minerals. The plates of specular iron are interstratified with a yellow amorphous mineral, which is probably iodyrite or iodide of silver. The quantity of the silver mineral is in such small quantities that I have not been able to isolate the iodine, but its appearance under the microscope and the indirect reactions obtained leave but little doubt. When larger quantities of the mineral can be obtained it will be interesting to determine the silver mineral with certainty. A better example of the importance of the microscope in the determination of mineral could scarcely occur. Iodide of silver has been found in the Cerro Colorado mine in Arizona, as stated in "Dana's Mineralogy."

Items of Interest from the Mines.

We give below items of interest from prominent mines, most of which are collated from letters of the respective Superintendents on file at the offices in this city:

There is still a heavy flow of water from the 650-foot south level in the Comanche, and also in the stopes and breasts.

The Hale & Norcross, Savage and Gould & Curry are still fighting the water.

They expect the 1750-foot level station in the C. & C. shaft to be set in about the 1st of May.

The cross-cut in the bottom of the winze of the Modoc now shows the ore to-day to be 17 feet wide, with the face still in fine ore. Work is slow as they have to hoist the ore 108 feet by hand.

The drifts in the 1700-foot level of Best & Belcher are being pushed ahead as fast as possible.

They are hoisting 250 tons of ore per day from the 1650-foot level of the Con. Virginia and expect soon to increase this amount.

In the Gila mine the shaft has passed through the porphyry and is now in the red conglomerate which overlies the lime.

The Golden Chariot is running on custom ore until the road will admit of hauling. Developments in the 6th cross-drift of the mine promise an extensive body of ore.

The face of the main drift 2900-foot level of the Crown Point mine is in low grade ore.

Last clean-up of the Eureka (G. V.) mine was 230 ounces of amalgam.

The ore body in the Electric is still 20 inches wide.

On the 22d inst. they had 35 feet to sink in the Ophir main incline to reach the 1900-foot level.

The indications for ore in the Eureka Con. mine continue encouraging.

In the Justice the 700 and 750-foot levels, the lateral drifts, present their usual fine appearance as well as the ore-producing stopes from 400 to 800-foot level.

The Belcher is taking out the usual amount of ore, which will pay a little more than the whole expenses of the mine.

They have 250 tons of ore at the mill and 150 tons on the dump at the Grand Prize mine.

Improved Lubricating Cup.

The accompanying cut shows Johnson's patent lubricating cup for journal boxes. The lubricator consists of a cylinder truly bored, to which is fitted a piston. The piston is forced

JOHNSON'S LUBRICATING CUP.

downward by means of a threaded stem passing through a removable cover or cap, with a hand-wheel on the outside. The lower end of the stem is made conical and fits a conical seat in the piston. The conical end is longer than the thickness of the piston and projects a short distance below it, thereby allowing the piston to drop if by any means the journal should become heated; an air hole in the cover, in that case, allowing air to pass through the piston.

These lubricators are neat, compact and well made. To apply these lubricators a thread is cut on the nipple and screwed into the cover of the journal. Before opening the cup for filling, the piston should be withdrawn to the top of the cup, then remove the cover, fill the cup, replace the cover, set down the piston by means of the hand-wheel until there is a pressure on the grease. Any kind of grease or compound of proper density can be used. It is a well known fact that by using any compound that by its density is retained on the journal, a large percentage of the cost of lubrication can be saved. By using these lubricators, a denser and cheaper compound can be used, than can be made to feed automatically. These lubricators are not claimed to be automatic feeders; the hand-wheel has to be moved downward, and no rule can be given as to the length of the intervals, as that depends upon the amount of friction and quality of the compound used. The engineer or person using the cups can easily regulate that according to circumstances. The lubricators are made and sold by the inventor, Geo. C. Johnson, Bracket street, Portland, Me.

Mechanical Defects in Micrometers.

(Read before the California Academy of Sciences, by Prof. George Davidson, U. S. Coast Survey.)

Some years since, I detected an apparent irregularity in the value of different parts of each revolution of the micrometer screw, and the irregularity or error was sensibly the same for each and every revolution. This peculiarity can be detected in regular astronomical observations by observing upon an object, for instance a close circumpolar star, with the micrometer placed systematically at different parts of each turn or revolution of the screw. It cannot be shown at observations at the whole turn only. It may not be shown by observations upon each half turn; but when observations are made at each fourth or fifth of each turn through a series of turns, the peculiarity of error is developed.

One or two hypotheses has been proposed to account for the error, but they were unsatisfactory, and I am led to the main source of error by careful examination, experiment and study. I found other sources of error, but none that gave a periodicity similar to that which I am about to describe. For example: the frame moved by the micrometer screw and carrying the micrometer thread, did not move smoothly and regularly in the micrometer box, $A A A A$, so that I saw a split in the frame at each angle, and thus formed the four light springs, $I I I I$. These press sufficiently against the sides of the

IMPROVED MICROMETER.

micrometer box to insure steady motion forward and backward.

In my examination of the working parts of the micrometer, the bearing, $a a'$, showed clearly that the shoulder, $b b'$, of the micrometer screw touched it in one place extending through an arc of not over 40° . Now it is evident that, notwithstanding such a projection as x may exist on the bearing, $a a'$, yet if the shoulder, $b b'$, were in all its parts a plane at right angles to the axis, c , as indicated by $b c$, and also if C fitted perfectly into $A A$, then the movement of the frame, $B B$, by the turning of the micrometer screw would, *cateribus paribus*, move uniformly throughout every part of each revolution.

But with such a projection as x existing, and likewise any inequalities existing in the plane of the shoulder, $b c$; and also, if the plane of the shoulder, as in the line, $b b'$, not at right angles to the axis of C ; then irregular movements of the micrometer thread, m , will take place, and these irregularities will be systematic for each and every turn.

If instead of the elevation, x , on the bearing surface, $a a'$, a depression existed under conditions analogous to those specified, then irregular movements of the micrometer will also take place. With a projection, x , on the bearing surface, $a a'$, suppose the plane of the shoulder is $b b'$, not at right angles to the axis of the micrometer screw and that for illustration, it stands as in the drawing, whilst the micrometer thread is standing at m . Now revolve the micrometer to the right one-half turn, until b' is placed over x . Did no projection, x , exist, the

micrometer frame would have been drawn downwards one-half the distance, a part of the threads of the micrometer screw, and the micrometer thread, m , would have been brought to m' ; under such conditions, the transit of a star over the thread at m and m' would have given the value of one-half revolution of the micrometer screw.

But the projection, x , existing, and the half turn being made, the part of the shoulder at b' is brought over x , and the micrometer screw, E , together with the micrometer frame, $B B$, is brought down bodily a distance equal to the height of x , so that the micrometer thread is not moved simply from m to m' , but from m to m'' , and the transit of a star over the thread at m and then at m'' would have given an erroneous value of the half-turn of the micrometer screw.

And similarly we might follow the movement of the micrometer through the other half of the turn, and in fact through every part of the turn. Also, we could trace the analogous action had there existed a depression, x' , instead of the elevation, x . The case I have presented is the simplest exhibition of this mechanical defect. It becomes complicated when a series of irregularities exist on the bearing surface, $a a'$, and in the shoulder, $b c$, of the micrometer screw. This examination and this explanation of one fertile source of irregularity in the value of the micrometer divisions in every turn suggests that the shoulder, $b c$, should be larger than ordinarily exists, and that in the final touches to the micrometer by the maker, the shoulder $b c$, should be ground upon the bearing surface, $a a'$, when the screw is in the position it will occupy when at work. Ordinarily the bearing surface is brass and the shoulder steel; but it appears to me that the bearing should be agate and the shoulders of steel.

It also suggests the idea that in all slow motion screws and in all tangent screws this source of error is more than likely to exist.

It will exhibit itself in tangent screws by the unequal and irregular action so frequently experienced by the observer when making the final touches to the delicate pointing upon a very small and sharply defined object.

In some observations upon *Ursa Minoris* to determine the arc value of the micrometer divisions, the time of the star's passage across the micrometer thread was noted when the screw was at the zero of each turn at the 25th, the 50th, and the 75th division. The following results were obtained from means of nearly 38 transits.

From the 0 division to the 25th, 44.2 sec.; from the 25th to the 50th division, 45.4 sec.; from the 50th to the 75th division, 39.2 sec.; from the 75th division to zero, 35.0 sec.

As the value of one revolution of the micrometer screw represented nearly 45° of arc, this time interval reduced in the proportion to the whole time interval would represent an arc, the following values:

From zero to the 25th division, 12°
From the 25th to the 50th division, 12.5
From the 50th to the 75th division, 18.8
From the 75th to zero, 9.7

With these data, and knowing the number of threads of the screw to the inch, we can readily compute the height of the irregularity. In other cases it was about the 1-2,600th of an inch.

Were it practicable to observe every eighth of a turn of the micrometer, still more accurate results could be derived for the proper correction necessary at any given reading from 0 to 100 in each turn.

But I suggest a much simpler, more available and probably a more satisfactory method by adjusting the micrometer over a finely ruled glass plate, and making a series of readings upon each line of the plate with the micrometer. These will not give absolute values of the error in the screw, but they will afford relative values throughout, and these relative values can then be applied to the absolute value obtained by astronomical methods for each whole turn.

It is not overlooked in this method of determination that the micrometer movement used to make the original rulings upon the glass plate may itself have a systematic error depending upon similar causes.

But upon making measures upon different parts of the ruled plate, its consistency may be determined, and, if found perfect, the method is open to no objection. It is a possibility, but barely a probability, that the micrometer screws may have the same systematic error, and the value of the telescope micrometer thus appear uniform. This may, however, be tested by reversing the ruled plate and making the measurement as before.

Asbestos is now used for a great many purposes, and nature seems to have formed it to be specially adapted to man's necessities. For steam pipe and boiler coverings it is unexcelled, and as a roofing material it is found a first-class article. It is used also as a base for paint, and the paint manufactured from it has a permanency of color and beauty of finish which is surprising. These paints are placed on the market ready prepared for the brush, in all shades. Asbestos is the best non-conductor in use and is made into covering for hot air and steam pipes, boilers, etc. Thompson & Upson advertise in another column a variety of asbestos materials.

It is generally believed that the great mining suit between the Richmond and Eureka Con. mining companies is in process of compromise.

The Proposed Ohio Bridge Law.

The Joint Committee of the two houses of the Ohio Legislature, appointed to investigate the Ashtabula accident, has reported a bill "to secure greater safety for public travel over bridges," which imposes certain restrictions on the construction of bridges, and gives directions concerning their inspection thereafter, such as have never been established by law in this country heretofore, we believe. The first section provides that all railroad bridges on standard-gauge roads shall be proportioned to carry the following loads per lineal foot for each track, in addition to their own weight:

Span.	Load per ft.
7 1/2 ft. (or less).....	9,000 lbs.
10 to 10 1/2 ft.....	7,500 "
10 1/2 to 12 1/2 ft.....	6,700 "
12 1/2 to 15 ft.....	6,000 "
15 to 20 ft.....	5,000 "
20 to 30 ft.....	4,300 "
30 to 40 ft.....	3,700 "
40 to 50 ft.....	3,300 "
50 to 75 ft.....	3,200 "
75 to 100 ft.....	3,100 "
100 to 150 ft.....	3,000 "
150 to 200 ft.....	2,900 "
200 to 300 ft.....	2,800 "
300 to 400 ft.....	2,700 "
400 to 500 ft.....	2,600 "

In all bridge trusses, of whatever length, the several members in each panel shall be so proportioned as to sustain, in addition to its share of the uniform load, as above stated, such concentrated panel load as is provided by the bill for a bridge of a length equal to the length of the panel.

Section two provides that every railroad bridge shall be so constructed as to be capable of carrying on each track, in addition to its own weight, two locomotives coupled together, each weighing 91,200 pounds on the drivers, within a space of 12 1/2 feet for each locomotive, followed by cars weighing 2,250 pounds per lineal foot covering the remainder of the span. The loads named in Section one must not strain any part of the material beyond one-fifth of its ultimate strength.

Section three prescribes that all highway bridges shall be constructed to carry the following loads per square foot:

Span.	For heavy traffic.	Other bridges.
30 ft. (and less).....	110 lbs.	100 lbs.
30 to 50 ft.....	100 "	90 "
50 to 75 ft.....	90 "	80 "
75 to 100 ft.....	80 "	75 "
100 to 200 ft.....	75 "	70 "
200 to 400 ft.....	65 "	50 "

The floor-beam strength of each floor-beam for each wagon way of bridges in cities and near large manufactories shall be not less than 13,500 pounds; for other bridges, not less than 11,250 pounds.

Section four provides that the stress on the best quality of wrought iron used in bridges shall not exceed, in tension, 10,000 pounds per square inch for long bars or rods, and 8,000 pounds for short lengths; and against shearing, 7,500 pounds. For the best quality of wrought iron in beams, the strains must not exceed, in compression, the following:

Length in diameters.	Minimum strain.
	Square ends. Round ends.
10.....	10,000 lbs. 7,000 lbs.
10 to 15.....	9,000 " 6,500 "
15 to 20.....	8,000 " 6,000 "
20 to 25.....	7,500 " 5,500 "
25 to 30.....	6,500 " 5,000 "
30 to 35.....	6,000 " 4,500 "
35 to 40.....	5,500 " 4,000 "
40 to 50.....	5,000 " 3,500 "
50 to 60.....	4,500 " 3,000 "

If iron of inferior quality be used, the stress shall be proportionately less.

Section five directs that cast iron be used in compression only, and in lengths not exceeding 20 diameters, with the same stress as prescribed for wrought iron in the act: "In shapes other than square or cylindrical, whether wrought or cast iron be used, the stresses shall vary accordingly."

The greatest allowable strains per square inch on wood in bridges is given in Section six as 1,200 pounds for oak and 1,000 pounds for pine, in tension; and for these woods in compression, according to their lengths in diameters, as follows:

Diameters.	Strain in Compression.
	Oak. Pine.
10.....	1,000 lbs. 800 lbs.
10 to 20.....	800 " 700 "
20 to 30.....	600 " 500 "
30 to 40.....	400 " 300 "

Section seven makes it the duty of railroad companies or other corporations erecting a bridge for public travel, by contract or otherwise, to keep on the spot a competent engineer with power to reject any piece of material which may have been injured or may be imperfect from any cause.

Section eight provides that all bridges used for public travel, of more than 15 feet span, or having a truss shall be inspected monthly by some competent person in the employ of the corporation owning the bridge, "for the purpose of seeing that all iron posts are in order, and all rivets screwed home, that there are no loose rivets, that iron rails are in line and without wide joints, that the abutments and piers are in good condition, that the track rails are smooth, and that all wooden parts of the structure are sound and in proper condition, and that the bridge is safe and sound in every respect." This inspector is to report once in two months.

Section nine provides for the inspection of highway bridges.

Section ten requires that all railroads in the State, within 60 days after the act goes into effect, shall report to the Railroad Commissioner a detailed statement of all bridges on their lines of more than 15 feet span, or having a truss.

Section eleven directs that the Governor, on the nomination of the Railroad Commissioner, shall appoint "some competent expert, at a salary not exceeding \$3,000 a year, who shall have cognizance of the construction and maintenance of every bridge intended for public travel in this State, and who shall hold his office for the period of five years, unless sooner dismissed by order of the Governor for reasons affecting his efficiency, in which case such reasons shall be given in writing by the Governor." This expert must pass an examination as to his competency before a committee of three members of the American Society of Civil Engineers. He will be subject to the direction of the Railroad Commissioner.

Section 13 directs that all persons having in charge the letting of a contract for a bridge of more than 35 feet span, shall submit to this expert a strain sheet and drawings of the proposed structure before work on it is begun, and the expert "shall certify its correctness, if correct, and make such alterations as may be necessary, if faulty in design or scanty in materials, according to the standard prescribed in this act; and on the completion of such bridge, said expert shall critically examine the work in all its details, comparing and verifying the sections on the strain sheet with those of the actual structure, and if these last are insufficient, forbid the use of the work till the bridge is made sufficiently safe and strong."

Section 15 directs that there may be an appeal from the decision of the expert to the Railroad Commissioner.

Section 16 provides that the Railroad Commissioner shall stop the running of trains on railroads which neglect or refuse to comply with the act, and provides punishments for false reports, etc.

Section 17 provides that the standard loads of narrow-gauge roads may be 30 per cent. less than those prescribed for other railroads.—*Railroad Gazette.*

Treating Base Metal Ores.

"Stewart's New Process."

We take from the *Colorado Miner* the following description of the process now employed for treating base metal ores in Colorado:

The difficulties encountered in treating refractory or "base metal" ores by amalgamation is generally owing to the presence of the following minerals, termed "base metals," viz.: iron, copper, lead, zinc and antimony; and, in roasting gold and silver ores of this class, as ordinarily conducted by the addition of common salt for the purpose of converting the silver to a chloride, the base metals are changed to the condition of sulphates, sulphates, oxides and chlorides. While the oxides of iron, copper, zinc, etc., are not soluble in water, yet when they enter the pan or barrel in presence of metallic iron and the undecomposed salt and sulphate of soda coming from the furnace, there is formed soluble iron, copper, zinc, lead, etc., which in presence of metallic iron are precipitated, and assist in sickening the mercury and in the decomposition and loss of the same, and while a simple hot water leaching would remove the soluble chlorides and sulphates, yet the oxides will, as before stated, remain in the pulp and do their proportionate share of harm. Experience has proven the fact that, when the base metal salts are kept in solution, or are thoroughly and effectively removed from the roasted ore, the gold or silver amalgamate readily and completely; and as amalgamation is the most economical method known of gathering the gold and silver in a convenient form for reducing to metal, it is not a matter of surprise that so much time, money and skill have been devoted to the object of amalgamating closely; that is, to extract the noble metals to within a close per cent. of the ore contents, by means of mercury.

The Hunt, Douglas & Stewart bath of protochloride of iron and chloride of sodium, when used in wooden vessels and at a temperature of 160° to 180° Fah., (and with or without the use of sulphurous acid or fumes, according to the nature of the ore,) acts upon the oxides of iron, copper, zinc, etc., converting them to soluble chlorides. The oxychloride and dichloride of copper, which are insoluble in water, are also attacked by the bath and rendered soluble. The chloride of lead which is soluble in water, is also soluble in the bath. So that not only all the base metal salts which are soluble in water, but also those which are not, are by the bath converted to soluble salts and are held in solution during the amalgamation of the silver or gold, and are afterward readily removed from the ore. Not only this advantage is gained, but the oxychloride and dichloride of copper, which are so destructive to the mercury and a hindrance to the amalgamation of the gold and silver where water and metallic iron are used, are, by the use of the bath, made to do good service, as the copper, salts and mercury decompose the sulphides and sulphates of silver, and chloridizes the same, increasing the yield of the silver above the furnace chlorination; also the copper is saved at an expense of a little more than the cost of old scrap iron.

The mechanical appliances employed, and recommended by Mr. Stewart, are as follows. A store tank for holding the bath. Purvine wooden pans and settler, a large filter tub for filtering out the chlorides, sodium included, some precipitating tubs, an evaporator and a washing pan for gathering the mercury, before allowing the pulp to pass into the creek.

The roasted ore (containing copper either naturally or artificially mixed) if brought to the

pans, and charged with a supply of the bath from the store tank, the pans being in motion, no water as in ordinary amalgamation, is used. About two hours is allowed for heating and chloridizing, the mercury is then added, and in six hours the whole is discharged into the settler. If the pulp is not thin enough in the settler, more of the bath liquor is added. In about seven hours the mercury and amalgam is drawn off and put into straining sacks, while the pulp and liquor is put into the filter tubs. From these filter tubs all the soluble base metals are filtered out by the addition of more bath liquor. Hot water is then added which filters out the salt. The liquors from the filter tubs are conducted through tubs for precipitating the copper, etc., then to the evaporator and store tanks for use again, while the ore or pulp from the filter tubs, after being thus cleansed of copper, soluble base metals and salt, is discharged into the washing pan for gathering the remaining mercury and is then run into the creek as worthless.

In the application of this process to amalgamation it will be observed that two very important results are secured, which renders amalgamation a perfect success either on raw or roasted ores, while without it, amalgamation cannot be so considered. First: The Hunt, Douglas & Stewart bath of protochloride of iron and chloride of sodium, used at from 15° to 20° Baume, or over, dissolves and holds in solution the base metals, while nothing but the silver and gold are precipitated by the metallic copper and mercury, hence the mercury is not decomposed or floured by the base metals, and a saving is thereby effected; also the silver and gold are nearly pure. Second: When the liquor and pulp are discharged from the settler into the filter tub, the base metals (including the copper) are filtered out, and also the chloride of sodium, all of which are saved by precipitation; the copper in its place, and the chloride of sodium, iron, zinc, etc., in their places, and these chlorides are used again for chloridizing fresh charges of ore; so that a close extraction of the silver, gold and copper is obtained, the loss of mercury is reduced, and a great saving of salt is effected.

The extra expense for labor over ordinary amalgamation will not exceed one dollar and a half per ton of ore, which is compensated by the copper, salt, mercury and additional amount of gold and silver obtained; sufficient in many cases to pay the whole expense of reduction as ordinarily conducted. The process has been used with gratifying results in this city, and is being applied at other places. The right to use the same will be granted at reasonable prices, and purchasers will be provided with complete specifications and plans of the plant required, and full instructions for working the process. Any intelligent workman can learn it in a short time, as it is exceedingly simple, and but little machinery used.

The Big Horn Country.

There seems to be no longer any doubt that the Big Horn country will be fully explored the coming summer, as expeditions are already fitting at Rawlins, Laramie, Corinne, Omaha, Grand Island and Sidney to go to the headwaters of the Big Horn river and prospect the country. It was Father DeSmet, we believe, who first told of gold deposits in the Big Horn country, and from that day to the present moment that region has been looked upon as fabulously rich in gold and silver. Numberless expeditions have been fitted out having for their objective point the Big Horn mountains, but none of them ever found the promised land. Like the fable of Captain Kidd's buried treasures, the failure of one party only makes others more anxious to discover the truth or falsity of the supposed gold fields. We trust that all of these parties will succeed in reaching the enchanted region, and that the Indians may not give them any excuse for leaving until the character of the country and its value are fully established. The discovery of really rich mines in the Black Hills gives much encouragement to the belief that the wonderful tales told by the Indians and old trappers are not idle boasts. It is probable that the soldiers will keep the Indians so busily employed in looking after their own safety that they will have little time to devote to scalping prospectors, and once in the mountains the danger would be a great measure lessened. These expeditions may not find gold, but it will be the means of opening up the country to settlement, for where a country presents the agricultural and pastoral advantages that the Upper Big Horn valley is known to possess it cannot long remain unoccupied. So that whatever may be the result of the expeditions now forming for exploring that region, the final result will be beneficial to Montana, as the settlement of the Big Horn would open up a new and short thoroughfare from Montana to the Union Pacific which would shorten the distance to the East at least 500 miles over the present route by Corinne, and that, too, over a much better country. If good mines are discovered it would be the best thing that could possibly happen to our Territory, as a railroad would be certainly built from Cheyenne to the mines, and there would be a good prospect of its being continued to the business centers of Montana.—*Helena Independent.*

It is said that Victor Hugo looks hale and strong, and attributes his health to his love of cold water and open windows.

The Soap Mine.

A correspondent of the *Ventura Free Press* gives the following concerning the operations of the Rock Soap Company, whose mine is in that county: The company commenced the year under embarrassing circumstances, having contracted previously to ship the rock to a second party in San Francisco, who was to manufacture and sell the article independent of the company. Under their contract, the amount of crude rock to be supplied was limited to one ton per month. The company took the manufacture of the article into its own hands some time in June and used in the first three months over four tons of the rock. The shipments for the last three months amount to 14 tons—an actual increase in the shipments of nearly four tons per month. The sales the past 10 months aggregate nearly 40 tons. The company have not only advanced by their enterprise the commercial interests of our county, but they have made improvements at the mine and in the facilities for getting out the rock. They have constructed a good wagon road two and one-half miles over a rough mountain region from the coast, at considerable expense, so that now the rock is hauled direct from the mine to the wharf. They formerly packed it down to the stage road on donkeys.

Notwithstanding the prospects of a dry year, the company are confident the manufacture and sale of their soap will continue to increase even more rapidly than last year. Agencies have been established in England, France and Germany, and the shipping at San Francisco is accepting it as the finest salt water soap in use.

The future of our county will be greatly brightened by the development of this one interest. The inexhaustible mountains of the material, and the hauling, the shipping and the quarrying will afford employment and business for all time. This, with our oil wells, will most certainly aid in the rapid settlement and permanent development of the county and southern California.

The Curry Pumps.

The pumps of the Gould & Curry are at work and behave like veritable old-stagers. They were first run on one-foot, then on two-foot strokes, and so on to the full stroke of eight feet. These strokes were made at first only once in two minutes, then faster and faster, up to eight strokes per minute. They are capable of being run to 12, but will not be required, unless more water is encountered, to run more than two or three per minute. The pumps are 14 inches in diameter and eight-foot stroke, and therefore capable of discharging between 60 and 70 gallons per stroke, and if run to their full capacity, can hoist from the 1700-foot level 750,000 gallons every 24 hours. The engine is a compound horizontal, with an initial cylinder of 27 inches in diameter and an expansion cylinder 48 inches in diameter. These cylinders are both attached to one piston rod, from which connection is made directly to the bishop-head of the bob, thus doing away with all the friction and liability to break of intermediate gearing. The engine is controlled by the Davy differential valve, whereby it can be made to make one stroke in ten minutes or 12 strokes in one minute, or any required number of strokes between these two extremes. The economy of the construction of engines in this manner will be apparent when it is considered that the engine consumes no steam when not in motion, and makes the stroke just as quickly when running slow as when running fast. The engine has been constructed and put in place under the supervision of W. H. Patton of this city, civil and mechanical engineer, and constructing engineer of the Consolidated Virginia, California, Belcher, Savage, and other mines, who has put up several similar engines on the Comstock, every one of which works admirably.—*Virginia Enterprise.*

A NEW DISTRICT.—The *Los Angeles Express* says: A valuable discovery of rich ores has been made on the backbone between the Colorado desert and the valley of that name. The first discovery in the district was made four years ago by John Bullock, the discoverer of the celebrated Castle Dome mines on the Colorado. The name of the district which was organized about two months ago, is the "Southern Pacific Railroad District." Nat. Small, an old Comstock miner, station keeper at Canyon springs, has been a leading spirit in the opening of this district, together with Hank Brown, a veteran stage man and freighter between Southern California and Arizona. The situation, etc., of the principal mines is as follows: Nineteen miles northeast from Canyon springs station, and 35 miles from Dos Palmas station, on the Southern Pacific railroad. A salubrious situation, not more than a hundred degrees average range of thermometer, 2,512 feet above the level of the sea. A good road leads from the railroad station at Dos Palmas to the mines. It is six or seven miles from the mines to the springs on the "bench," where a large flow of water is obtained—a sufficiency of wood is to be had for mining purposes to a considerable extent. All the ledges show a slate and granite formation, and have footwalls of the same.

We can recommend the New York watch, of Springfield, Mass., as A 1.

Steam Engines & Boilers,

NEW AND SECOND-HAND.

One Patent Straw-Burning, Portable En-
gine, (new,) fire box boiler, the best
Portable Engine on the coast; built
by Ransom, Sims & Head, Ipswich,
England.

One Steam Fire Engine, second-hand,
in excellent condition, with 200 feet
leather hose, very cheap, just the thing
for a small town. Button & Blake,
builders, Waterford, N. Y.

One second-hand Stationary Engine, 14x30
inches, link motion, with or without
hoist gear.

One second-hand Stationary Engine, 8x20
inch, with or without hoist gear.

One Upright Boiler, Horizontal Engine
on wheels, Eastern make, 7x12.

One Upright Boiler, Horizontal Engine,
San Francisco make, 6x12.

One small Stationary Engine, 3½x7 inch.

One Steam Boiler, 40 inches diameter, 16
feet long.

One 8x10 Straw-Burning Portable Engine.

One Stationary Engine, 8x16, and Boiler,
with pump heater, fire front and smoke-
stack, complete.

One Traction Engine, three wheels, rub-
ber tires, double cylinder, 6x10 inch;
Thompson's patent, D. D. Williamson,
builder, New Jersey.

Various other second-hand Engines and
Boilers for sale cheap.

San Francisco Pioneer Screen Works,

J. W. QUICK, MANUFACTURER,

Several first premiums received
for Quartz Mill Screens, and Per-
forated Sheet Metals of every
description. I would call special
attention to my SLOT CUT and
SLOT PUNCHED SCREENS,
which are attracting much at-
tention and giving universal
satisfaction. This is the only
establishment on the coast de-
voted exclusively to the manu-
facture of Screens. Mill owners using Battery Screens exten-
sively can contract for large supplies at favorable rates.
Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

the first-class appointments of the house, make it a favorite with the traveling public.

DEWEY & CO. PATENT AGENTS.

Office—224 Sansome St., San Francisco.

PATENTS obtained promptly; Caveats filed expeditiously; Patent-reissues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph. Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Soliciting Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in Patent business, enable us to abundantly satisfy our patrons, and our success and business are constantly increasing.

The shrewdest and most experienced inventors are found among our most successful friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

DEWEY & CO., Patent Solicitors.
San Francisco, 1877.

The Triumph of Art in Railroad Travel.

Year by year we note the footsteps of progress in many directions. In no direction is progress more palpable than in the facilities offered the railroad traveler of the present day. Looking back but a few years, we can see the toiling mail-like advance made day by day by the emigrant's wagon, as it was slowly but surely drawn toward sundown by the patient ox, or the slowly moving farm horse; then came the old-fashioned stage coach; following closely, we had the canal packet; then the steamer on the lakes and rivers; then the locomotive engine and the stage, like car. Now! the palatial coach, and more than palatial drawing room and sleeping car. Yet, not satisfied with these, that marvel of mammoth Western corporations, the Chicago & North-Western Railway, as we stated some weeks ago, has developed hotel cars that will, for elegance, usefulness and real comfort, eclipse everything of the kind that has been hitherto placed in service on any road. Some of our readers seem to have some doubts about the merits of hotel cars, or their superiority over the so-called dining car, that is run for a few miles on some roads. "I am not so sure about that," said one of our friends, as he had finished reading our first article about these hotel coaches that are to be run on the Omaha and California line of the Chicago & North-Western Railway, "I am not so sure I would care to take my dinner in any car, no matter how much like a palace, while running at the rate of 40 miles an hour." It is a saying, "that the faster you run the safer." Why, last June it will be remembered, that this road hauled from Chicago to Council Bluffs, in less than ten hours, the now celebrated "Jarrett and Palmer Train." On that train was a hotel car, not as large, with less wheels under it, poorer springs, and in no way as strong and easy for riding in as these new cars are to be, and yet, Mr. Jarrett said "while on the Chicago & North-Western line, running at an average rate of 50 miles an hour, we took our breakfast as comfortably as we would at Delmonico's, in New York."

It is well known that the Chicago & North-Western Railway is built over the most favorable line as to grades that could be found between Chicago and the Missouri river, with but few curves; its track is mostly of heavy steel rail, gravel ballasted, with wide roadway, giving it permanence and solidity—it is as smooth as a floor; all its cars strong; with plenty of wheels under them, and with springs so adjusted that the usual "bouncing" and oscillation is reduced to the minimum. We observed in an ordinary car the side motion and rising and falling of the car was less than half an inch, and sometimes scarcely perceptible. We believe it will be found that a person will sit in these hotel cars and eat or write as comfortably as he could at his desk or table at home; thus we choose to call the triumph of art in railway travel.

We learn that this new line of hotel cars is being pushed to completion as fast as the full force of workmen in the Pullman shops can do it. We shall be certain to see them in a few weeks.—Cedar Rapids Republican, Feb., 1877.

Canadian Patents for U. S. Inventors and Patentees.

It is only recently that the Canadian Government has granted patents to United States citizens. In consequence hereof the many immensely valuable inventions patented in this country are now patented in Canada. Patents are much sought for and are readily disposed of at fair cash prices. In our country about three-fourths of all manufacturing is based upon patents, especially in the New England States no manufacturing business of any consequence is started without being protected by such. Our neighbors across the border have not been slow in observing and learning that inventions and patents are the foundation of all prosperity in manufacturing purposes. Hence all our patents for labor saving and agricultural machinery and innumerable improvements in home comforts meet a ready market in Canada. Inventors and Patentees should therefore not delay to secure their patents in Canada; many good inventions are already pirated by Canadians, who, against law and right, appropriate United States inventions and have them patented in their own name. After a patent is granted it is extremely difficult to prove who is the first and original inventor. Therefore, inventors and patentees to be safe, you will have to secure your patents in Canada without delay. We have facilities for securing Canadian patents second to none. Our charges for securing Canadian patents are only \$65, which is from \$10 to \$20 lower than other solicitors. A model is required.

Inventors and patentees! do not delay and lose your opportunity. Things may change. With model and description of your invention send us \$25, and we will prepare all drawings and documents and forward them to you for signature. In about 30 to 50 days we can return your Canadian patent.

DEWEY & CO.,
Patent Solicitors, S. F.

ROASTING OF GOLD AND SILVER ORES, and the Extraction of their Respective Metals without Quicksilver, 1870. It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. Price \$2.50 coin, or \$3 currency, postage free. Published and sold at this office.

Superior Pianos for the People at Popular Cash Prices.

More than TEN THOUSAND prosperous families on this Coast need Ten Thousand GOLDEN PIANOS to make TEN THOUSAND HOMES MORE PLEASANT AND ATTRACTIVE.

Prices of good Pianos have long been too high. Our people could not afford to buy them. But many will find it not only pleasant but profitable to purchase

The Brilliant and Durable GOLDEN PIANO

Which we now offer the readers of this paper

At Greatly Reduced Popular Cash Prices.

We Guarantee them to be as represented, of superior tone, finish and durability.

Samples can be seen by calling at this office. We keep no expensive sales-rooms and attendants.

We shall sell none but superior and desirable instruments, but give our customers the benefit of prices far below any before offered on this side of the Continent.

Prices of the Golden Piano:

The Golden Piano, \$500	\$350
(UPRIGHT—C.)	
The Golden Piano, \$375	\$300
(SQUARE—No. 1.)	
The Golden Piano, \$500	\$350
(SQUARE—No. 2.)	
The Golden Piano, \$600	\$400
(SQUARE—No. 3.)	
The Golden Piano, \$800	\$450
(SQUARE—No. 4.)	

We invite our readers who wish to look at Pianos for themselves or friends, for immediate or future purchase, to call and examine our samples.

Those who cannot call will be supplied with further descriptions and recommendations by sending to this office.

To Ship and Engine Builders, Steamship Companies, Etc.

Mining and Other Companies.

California and Arizona Mining Company—

Location of principal place of business, 507 Montgomery Street, San Francisco, California. Location of works, Mohave County, Territory of Arizona.
Notice is hereby given, that at a meeting of the Board of Directors, held on the third day of April, 1877, an assessment (No. 2) of two cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin to the Secretary, at the office of the company, 507 Montgomery Street, San Francisco, Cal.
Any stock upon which this assessment shall remain unpaid, on the thirtieth day of May, 1877, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the fourth day of June, 1877, to pay the delinquent assessment, together with the costs of advertising and expenses of sale. By order of the Board of Directors, T. E. JEWELL, Secretary.
Office, 507 Montgomery Street, San Francisco, California.

California Fruit Growing Association.—

Location of principal place of business, San Francisco, California. Location of property, El Dorado county, Cal.
Notice is hereby given that at a meeting of the Board of Directors, held on the 14th day of April, 1877, an assessment, No. 4, of \$2.00 per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary at the office of the company, 331 Sansome Street, San Francisco, Cal.
Any stock upon which this assessment shall remain unpaid on the 21st day of May, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before will be sold on Saturday the 9th day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, HORACE JONES, Secretary.
Office, 331 Sansome Street, San Francisco, Cal.

Consolidated Bonanza Silver Mining Co.—

Principal place of business San Francisco, California. Location of works in Eagle and Washoe Valley Mining District, Ormsby county, State of Nevada.
Notice is hereby given, that at a meeting of the Board of Directors, held on the 19th day of April, A. D. 1877, an assessment, No. 1, of 10 cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary at the office of the company, No. 19 First Street, San Francisco, California.
Any stock upon which this assessment shall remain unpaid on Tuesday the 29th day of May, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday the 5th day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, WM. MARTIN, Secretary.
Office No. 19 First Street, San Francisco, Cal.

Dolores Consolidated Mining Company.—

Location of principal place of business, San Francisco, California. Location of works, Dolores Mining District, Esmeralda County, Nevada.
Notice.—There are delinquent upon the following described stock, on account of assessment (No. 1) levied on the seventeenth day of February, 1877, the several amounts set opposite the names of the respective shareholders, as follows:
Name. No. Certificate. No. Shares. Amount.
Blasdel, H. G., Trustee..... 16 10,000 \$1,000 00
Blasdel, H. G., Trustee..... 17 5,000 500 00
Blasdel, H. G., Trustee..... 18 5,000 500 00
Blasdel, H. G., Trustee..... 19 5,000 500 00
Drexler, L. P. & Co., Trustee... 8 25,000 2,500 00
Fry, J. D., Trustee..... 7 10,000 1,000 00
Keene, J. R., Trustee..... 9 10,000 1,000 00
Talbot, W. C., Trustee..... 3 100 10 00
And in accordance with law and an order of the Board of Directors, made on the seventeenth day of February, 1877, so many shares of each parcel of such stock as may be necessary, will be sold at public auction at the office of said company, on Monday, the sixteenth day of April, 1877, at the hour of two o'clock, p. m. of said day, to pay said delinquent assessments thereon, together with costs of advertising and expenses of the sale.
J. W. CLARK, Secretary.
Office, 418 California street, San Francisco, California.

POSTPONEMENT.—The sale of the above described certificates of stock is postponed from the 16th day of April, 1877, to the 16th day of May, 1877, and will then take place at the same hour and place as above named. By order of the Board of Directors. J. W. CLARK, Secretary.

Excelsior Silver Mining Company—Prin-

cipal place of business, San Francisco, Cal. Location of works, El Dorado District, Lincoln County, Nevada.
Notice is hereby given, that at a meeting of the Board of Directors, held on the twenty-fourth day of April, 1877, an assessment of ten cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold and silver coin, to the Secretary, at the office of the company, 305 Post Street.
Any stock upon which this assessment shall remain unpaid on the twenty-fifth day of May, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the eighteenth day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale.
W. A. KOLLMYER, Secretary.
Office, 305 Post Street, San Francisco, Cal.

Mariposa Land and Mining Company of

California—Location of principal place of business, San Francisco, California. Location of works, Mariposa County, Cal.
Notice is hereby given, that at a meeting of the Board of Directors, held on the 28th day of March, 1877, an assessment (No. 1) of one dollar per share was levied upon the capital stock of the corporation, payable immediately in United States currency, to the Secretary, at the office of the company, Room 33, Nevada Block, No. 309 Montgomery Street, San Francisco, California, or to the Assistant Secretary, at the office, No. 8 New York Street, New York.
Any stock upon which this assessment shall remain unpaid on the Thirtieth day of April, 1877, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Monday, the Twenty-eighth day of May, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.
LEANDER LEAVITT, Secretary.
Office, Room 33, Nevada Block, No. 309 Montgomery St., San Francisco, California.

Taylor Mill and Mining Company.—Prin-

cipal place of business, City and County of San Francisco, State of California. Location of works, Garden Valley Mining District, El Dorado County, California.
Notice is hereby given, that at a meeting of the Board of Directors, held on the twenty-ninth day of March, 1877, an assessment of Twenty cents per share was levied upon the capital stock of the company, payable immediately in United States gold and silver coin, to the Secretary at his office, No. 607 Montgomery Street, in the City and County of San Francisco.
Any stock upon which this assessment shall remain unpaid on the ninth day of May, 1877, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Friday, the twenty-fifth day of May, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

ARITHMETIC MADE EASY.

ROPP'S

EASY CALCULATOR

Is a new publication that must prove of incalculable benefit to Farmers, Mechanics and Business Men. It is so rapid and original as to startle the most scholarly, and yet so simple and practical that the most illiterate in figures can instantaneously become his own accountant. It enables thousands to accomplish in a minute what they could not learn to calculate in many months.

The first part contains an entirely new system of tables, which show at a glance the exact value of all kinds of Grain, Stock, Hay, Coal, Lumber, Merchandise, etc., from one pound up to a car load, and for any price that the market is likely to reach; the interest on any sum for any time at 6, 7, 8 and 10 per cent.; correct measurement of all kinds of Lumber, Saw Logs, Cisterns, Tanks, Granaries, Bins, Wagon Beds, Corn Cribbs; a Time, Wages and many other valuable tables.

The second part is a practical arithmetic, and embodies a simple mechanical principle which enables any one familiar with the fundamental rules to become a lightning calculator; and by which over two-thirds of the figures and labor required by the ordinary methods, and fractions with their intricacies, are entirely avoided.

The work is nicely printed on fine tinted paper, is well and elegantly bound in pocket-book shape and is accompanied by a Silicate Slate, Memorandum and Pocket for papers. It is by far the most complete, comprehensive and convenient pocket manual ever published.

Price, bound in Fine English Cloth, \$1.00.

Sent direct from the Eastern publisher, postpaid, on receipt of price, by P. O. order, registered letter, or receipted by express. Address

J. B. REYNOLDS,

(Room 10,) 320 Sansome Street

THE O'HARRA

CHLORIDIZING FURNACE

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this Process:

Two cords of wood at \$6.....	\$12.00
Two fires at \$4.....	8.00
1,500 lbs of salt at 1¢.....	22.50
Wear of shoes and power.....	1.50

Cost for 15 tons.....	\$44.00
Cost for one ton.....	2.93

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in the Peavine District. For further information, apply to

PICKERING ENGINE GOVERNOR.

VALLEJO FOUNDRY, October 17th, 1876.
Messrs. NEYLAN & YOUNG, San Francisco,
Agents for "PICKERING GOVERNORS."

Gents:—The 10 two-inch Improved Speed Adjusting Governors I bought of you this year for my patent Straw Burning Threshing Engines give splendid satisfaction. They far surpass for regularity of speed any Governor that I have ever seen, and I have seen all the best kinds; I have seen the main belt fly off the pulley several times this season while threshing, and the engineer did not discover it, so perfectly was the speed maintained, until he was told of it; this I consider something wonderful; I consider the Governor absolutely perfect, so far as speed is concerned. I bought and put on to one of my engines a Shive Governor, to see which was the best, and after one season's trial I have no hesitation in saying they are far superior to any other Governor that I have seen or used. I wish you would send me the lowest price that you can furnish 25 Governors for next season's engines.
Yours respectfully,
J. L. HEALD.

The only Governor that has received awards at each of the International Exhibitions. American Institute Fair, New York, 1865, Two Medals; Mechanics' Institute Fair, Baltimore, 1865, Silver Medal; American Institute Fair, New York, 1869, Two Medals; International Exposition, Paris, 1867, One Bronze and Two Special Medals; International Exposition, Vienna, 1873, Medal of Progress and Decoration; International Exhibition, Philadelphia, 1876, Medal and Diploma.

PATENTED CAST STEEL SHOES AND DIES.

Guaranteed Cheaper than the Best Iron.

IMPORTANT NOTICE.

Reduction in Price from 16 Cents
to 12 Cents Per Pound.

Owing to our largely increased business, the present low price of iron from which our Steel is manufactured, and the improved facilities for casting and forging, we take great pleasure in announcing that from and after this date we will supply our IMPROVED CAST AND FORGED STEEL SHOES AND DIES FOR QUARTZ MILLS at twelve cents per pound, delivered at San Francisco or Sacramento, instead of sixteen cents, as heretofore.

We also furnish Steel Plates for Blake and other Ore Crushers, Steel Gut Gearing, etc., for Mills and Hoisting Works, Steel Pan Shoes, Battery Cams and Tappets, etc., etc.

Address all orders, with dimensions or drawings, to

\$1,000 Challenge Ore Feeder,

AWARDED FIRST PREMIUM

At the Tenth Industrial Fair of the Mechanics' Institute.

It may be considered as now fully demonstrated, by careful and long-continued experimentation, that the plan upon which a perfect ore feeder must be constructed is that of the carrier, and not that of the shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply dropped. Spasmodic or jerky contrivances will not answer the purpose.

REFERENCES.

A letter received from the Julian Mill, Newcastle, says of the Carrier Feeder: "It is the most perfect Feeder we have ever seen; don't see how any mill can do without them."—A letter from Mr. C. G. Belding, of Amador County, speaks in the highest terms of them.—Two of the machines were shipped to the Bunker Hill Mill, also Gover Mill, Amador County.—Mr. Stevenson, of Boston Mill, Gold Hill, Nevada, says they are the best Feeder he has ever seen.—Soulsby Mill, Tuolumne County.—California Company, Nevada City.—Omaha Gold Mining Company, Grass Valley.—St. Patrick Mill, Placer County.

\$1,000 CHALLENGE.

Backward in Coming Forward.

C. P. Stanford Fails to Come to Time on the Challenge of \$1,000 to Test the Merits of His Ore Feeder as Against Mine. The Challenge is Still Open to Him or any one else. GENTLEMEN, Put up or Shut up.

A letter has been received from the Crescent mine, Plumas County, in which it states that the Tulloch is a failure as against the \$1,000 Challenge Feeder of Hendy's.

We warrant the machines to give perfect satisfaction, and to be a better and more durable Feeder than any other in the market, and will sell them as cheap as any other of its class.

VOLUME XXXIV.
Number 18.

Walker's Compound Steam Pump.

We give on this page, engravings illustrating the Walker patent compound steam pump, recently introduced on this coast by Parke & Lacy, agents. This pump delivers a constant stream, and can be worked either with steam or compressed air, having many special advantages over ordinary pumps. The sectional view is that of an ordinary piston pump. The other engraving represents a new pattern, plunger pump, arranged especially for underground mine work, in dirty water. Messrs. Parke & Lacy have had the pattern pump made especially for mining purposes to meet the requirements on this coast.

The mechanism of this compound pump can readily be understood from the sectional view. The elongated piston has two ends provided with packing, and has a cylindrical portion of a lesser diameter, extending between the two ends, the said portion being fitted to work steam-tight in a central partition in the cylinder; two annular chambers are thus formed into which steam is admitted to act upon the smaller areas of the piston ends, and it is afterward expanded into the spaces between the piston ends and the cylinder covers, to act upon the larger areas of the said piston; a double cylindrical valve regulates the movements of the steam, each half of it being formed with a passage to connect two ports through which steam passes from the annular space to the space between the piston and the cylinder head, and also with a passage which connects the larger steam space with the exhaust passage. Steam is admitted into a space between the two parts of this valve, and finds its way by suitable openings into the end spaces between the said valve ends and the valve box covers; the said end spaces are connected by passages with ports formed in the aforementioned partition, and as the piston moves to and fro, passages formed in the said piston establish a communication between the said ports and a port leading into the exhaust passage, thus relieving the valve from pressure on one end and causing it to be quickly pushed in that direction by the steam at the opposite end; the parts are all so arranged as to provide effectually for sufficient steam to cushion both the piston and valve so as to prevent striking under any circumstances.

The indicator diagram shown on this page was taken from one of these compound cylinders, and a study of it will demonstrate the economy of such a pumping engine. Experts will also notice the very short passage-ways for live steam between the valve and the high-pressure piston, insuring a small waste of steam from steam passages. Messrs. Parke & Lacy, agents for the Burleigh rock drills, air compressors and other mining machinery, 417 Market street, will furnish further information concerning this pump to those desiring it.

MINT COINAGE.—The U. S. Branch Mint, in this city coined in April 3,062,000 pieces of money, valued at \$4,326,000. The sum of \$2,880,000 of the amount was in twenty-dollar pieces.

ADVICES from Ohio state that 400 coal miners at New Straitsville, struck on Monday against a reduction in the price of mining to 30 cents per ton. Some trouble is expected.

MINING SUIT.—In the Twelfth District Court, H. S. Moore has brought suit against Isaac Yoakum, Sr., to recover possession of mining property in the Long Town mining district, Kern county, together with \$50,000 damages. The property consists of 1,500 feet of the Isabella vein, situated in section 22, township 27 south, range 29 east, and called the Isabella quartz mine. It is alleged that the defendant unlawfully ousted the plaintiff from the property in August, 1876. Before that time the plaintiff and one Henry Burdett were the owners of the

DECISION IN THE EMMA MINE SUIT.—The suit of the English owners of the Emma mine against Trenor W. Park and others, to recover the \$5,000,000 paid for it, alleging that there was fraud and misrepresentation of the mine, resulted in a verdict for the defendants. The verdict was received with demonstrations of delight, which, however, were speedily checked by Crittenden, counsel for the defence. Trenor W. Park, the principal defendant, sat in his chair almost powerless with emotion and the tears burst from his eyes. Having recovered himself

The Mining and Scientific Press.

We consider it nothing more than proper occasionally to call the attention of our readers and others to the merits of the MINING AND SCIENTIFIC PRESS. It is our endeavor to furnish as good a journal as possible to the industrial classes of the Pacific coast, and we are happy to feel that our endeavors are appreciated. The Press has a good circulation in every mining camp and town on the coast, and is looked upon as a necessity in the cabin of every intelligent miner who wishes to progress in his business. No issue is ever printed that does not contain some hint of value which can be profitably applied in the duties of every day life. We gather all the current mining news of the day and arrange it in such a shape that it is easy of reference and in a condensed form. All the new laws and decisions that are of interest to the mining community are published in this journal; and all the new processes in metallurgy and new systems in mining are fully described. In fact everything that will be of interest or value to the miner or mechanic is carefully looked after and furnished.

The Press is the only paper of its class published on this coast, and no miner or mechanic can afford to be without it. We take care to glean from foreign publications anything of use or value to Pacific coast readers, and keep track of all new inventions that will be likely to be serviceable to the intelligent and progressive readers of this coast. The Press has now been published so long that its proprietors and editors are fully aware of the needs of the community which it represents, and therefore everything is given in as condensed form as possible to suit a busy people who have no time to read a column when the information could be conveyed in a paragraph.

All our old subscribers who know the advantages of having the Press at hand and are familiar with its merits should take occasion to urge upon others the propriety of encouraging a first-class home industrial journal. There are many persons not now subscribers of the Press who would be benefited by weekly reading its columns. The attention of many of these, needs only to be called to the subject by some one familiar with the paper to induce them to subscribe. An illustrated journal of this character is an expensive one to publish, and all who are engaged in industrial pursuits on this coast should do their share towards maintaining a first-class paper devoted to their interests. Those familiar with the merits of the Press can do much to assist us in our work, with very little trouble, by calling the attention of their friends to it and occasionally writing for us. There are many things which come under the observation of the practical every day worker which would be to the advantage of others to know in the same business. To aid in the diffusion of knowledge is one of the duties of the citizens of our republic, and if such things are sent to us we will be pleased to do our share in the good work. Fine writing is by no means necessary; if the facts are sent we will arrange the matter for publication.

The present daily ore yield of the mines is as follows: Consolidated Virginia, 450 tons; California, 500; Justice, 450; Chollar-Potosi, 120; Ophir, 30, Belcher, 85. Total, 1735 tons per day.

SECTION OF WALKER'S COMPOUND STEAM PUMP.

SPECIAL COMPOUND STEAM PLUNGER PUMP FOR UNDERGROUND WORK.

suit, therefore, is to decide the ownership rights of the parties.

New gold diggings are reported in the Takon country, Alaska Territory, that will pay \$5 to \$10 to the hand. It is a pretty hard country up there though, unsettled, rough and expensive to live in. The miners can only work a few months in the year.

SECRETARY SCHURZ has appointed H. H. Bates, B. R. Catlin and B. C. Tiffany to the grade of principal examiners of patents.

with a notice of two more suits against him for alleged fraud in connection with the Emma mine company claims, in each an aggregate of nearly a million dollars, and one of them is brought, it is stated, by one of the witnesses of Park in the trial which has just closed.

THE last issue of the Oroville Mercury states that since there is no snow in the mountains the miners are turning their attention to the river. Doubtless more river mining will be done this year than during many previous years.

CORRESPONDENCE.

Mining in Elko County, Nevada.

[From Our Traveling Correspondent.]

(Continued.)

Brief allusions have been made from time to time to the value to be derived from good, cheap and convenient facilities for the reduction of the ores of our mines. Mills are everywhere in demand. More would have been built but for the chariness of capital in taking risks. This is not surprising. When chances are taken it is perfectly natural that the charges for reduction, or the price paid for the ore, should be somewhat in the ratio with the risks to be run. In the absence, too, of competition, it is a well established law that money has a tendency to take all the advantages wielded by the power it commands, within the bounds of what is believed, at any rate, to be promotive of its true interests or its further accumulation. On the other hand, labor is often suspicious. It is too ready to charge capital with exacting exorbitant rates, of not giving full returns, or not paying for ores purchased in accordance with their true value. In consequence of this war between conflicting forces many good mines go unworked, much valuable ore lies unsold on the dump, and the progress of many an excellent district is greatly retarded. Let the miner throw away his unjust suspicions and unreasonable expectations. Let the millman be satisfied to take some chances with the miner, allowing him an equal or proportionate share of the profits—if need be, securing some interests of his own, that he may not be at the mercy of the mine owner—and a new and powerful impulse would be given to the entire mining interests of the coast. It would be felt from California to Colorado, and from Montana to Arizona. A good custom mill seems to be much needed at

Cornucopia.

Had this want been in time supplied she would long since have turned out her rich ores, as the name implies, in great abundance. As now, with stocks at the lowest ebb, it may be aptly as well as literally translated with a little pardonable erring, plenty—in a horn; for as the shares of the principal mines are held largely at home, the depression is as sensibly felt and as plainly visible here as its gloomier counterpart on your more crowded streets.

The Main Mineral Belt

Extends two miles or more, from north to south, through porphyry, flanked east and west by a hard, ferri-ferrous syenitic rock, not unlike, in appearance, the dolerite in the vicinity of the Comstock. The main north and south lode, on which the Leopard and Hussey are located, hugs the western side of the belt, in close proximity to the syenite, while that occupied by the Panther and Tiger (names, by the way, a little too suggestive of the wild species of the genus feline), is, nevertheless, believed to be a true fissure, cutting across the porphyry at right angles with the general trend of the Leopard vein and the main mineral belt. On the surface ground, more particularly of the last named mine, the quartz and porphyry are almost a *fac simile* of those found on the Comstock. Here the yellow porphyry gradually changes as depth is attained to that peculiar blueish cast, so characteristic of the same as everywhere seen on the dumps of Gold Hill and Virginia City, coming up from the lower levels; while the quartz passes from the same well-known color of the surface rock to a fine white, except when it is streaked and shaded, as there, by the dark tints imparted by the black silver-bearing sulphurets. Other parallelisms might be drawn, but little less striking. The facts are thought worthy of mention, as nowhere in the State, or elsewhere on the line of our travels, has a similar co-incident likeness been observed. The ore croppings of

The Leopard

Are 300 feet in length and from two to seven feet in width, while the porphyry described, somewhat peculiar to this lode, is from 150 to 200 feet across. It is probably well known that the mine paid well from the very surface, having had many dividends with but few assessments. As it is the leading mine of the district, a little more of the usual detail as to workings will be allowable. The greatest depth by shaft is 600 feet. On the 200-foot level the ore commenced 75 feet north of the shaft, and was followed all the way south by a drift 380 feet, all of which has been mined. The ore was found on the 300-foot level opposite the shaft and a drift run of 180 feet. On the 400-foot level a drift of 232 feet has been run, the ore being reached at the distance of 75 feet south of the shaft, and still seen in the face of the drift. A drift south on the 500-foot level of 225 feet, struck the ore body 127 feet from the shaft, which is found pitching west. From this drift about 700 tons have been stoped. On the 600-foot a drift has been extended south from the foot of shaft 250 feet. A cross-cut, from a point 100 feet south of shaft, has been driven west 150 feet, and another cross-cut of 34 feet run west from a point 200 feet south of shaft. The east wall of ledge is supposed to have been cut on the 500-foot level, 70 feet east of shaft, but has not been

found at the greatest depth on 600-foot level. It is thought that the cross-cut of 100 feet on the lowest level is within 25 feet of the ore chimney, as some bunches of fine rock have been passed through—the quartz in the cross-cut assaying from \$144 to \$785 per ton.

Since Mr. F. F. Coffin, the present Superintendent, took charge last August, nearly 6,000 tons of ore have been extracted, giving sample assays of \$143 per ton.

The explorations leave large bodies in sight with indications of soon reaching a larger and richer bonanza than any yet discovered. Such at any rate is the hope. In connection with the property there is a fine 20-stamp mill for dry crushing, provided with one of White's roasting furnaces, the usual complement of pans and other required equipments.

The South Leopard,

Adjoining, Mr. J. A. Norton, Superintendent, has put up steam hoisting works. A shaft for prospecting the mine has reached the depth of 125 feet. Having passed some 60 feet through the iron syenite, it is now sinking in the porphyry, with a fair prospect of finding ore by going deep enough, or drifting far enough east and west, as the location is on the general line of the lode.

The Hussey,

Lying north of the Leopard on the same lode, has reached the depth of 500 feet, and is at present taking out a considerable amount of ore, with probably 300 tons on the dump. In the temporary absence of Mr. C. C. Perkins, the Superintendent, but few facts could be gathered—a matter to be regretted, as it probably stands next in importance to the Leopard, in view both of the extent of developments and the quantity and value of ore, hitherto extracted or in sight. The different classes of ore from the two mines are in most respects similar.

Fifty tons worked in February last yielded from \$130 to \$140 per ton, which may be taken probably as something like an average of the ore as it comes from the mine. Whether a sufficient quantity can be supplied to justify the erection of a mill was not learned. If not, the deficiency could doubtless be made up from the Panther, Fissure and other mines of the vicinity.

The Fissure Mine, (Hogle & Co.)

On Silver hill, nearly opposite the South Leopard hoisting works, has been opened on the surface at several points, and at one place for 50 feet in length and to the depth of 15 feet, from which ore is at present being extracted. The developments show a six foot vein with a direction northerly and southerly with the general course of the belt. The ore assays in silver from \$45 to \$210 per ton—the highest assay running \$18 in gold. A tunnel has already been driven 210 feet. An extension of 175 feet further will tap the ledge at 300 feet from the surface. The enterprise is looked upon as big with promise, with scarcely a shadow of doubt hanging over the result.

The O. K. Mine,

Owned by Messrs. John Campbell, M. Bisheoff and others is admirably situated for working on the crest of the mountain, 3,000 feet south of the Leopard and Fissure and on the same great mineral belt, as the formation, as well as the quartz is very similar in character. A tunnel cuts the vein at 55 feet from the surface, and two shafts of 50 feet are sunk on the croppings and lode from six to 12 feet. The south shaft struck a chimney of good ore near the surface. It is estimated to work from \$60 to \$75 per ton, and appears to have held out in value as far as followed. A new shaft is about to be lowered on the vein from the end of the tunnel to the depth of 100 feet and a drift run thence south along the lode with the double purpose of further developing the mine and at the same time prospecting the ground of the Winnemucca adjoining in that direction.

The last mentioned claim belongs to Messrs. Ottenheimer and Sullivan of Cornucopia, and has already been opened sufficiently to show a four foot vein of good looking quartz, with as beautiful a foot wall as one could well wish to see.

Returning to the more immediate neighborhood of the Hussey and Leopard,

The Panther

May be seen on a ridge which it follows to a considerable elevation from the west to the east for the distance of 1,500 feet. Powder has evidently not been burnt in vain. Many an effective shot has been heard.

At a point near the west end a shaft of 40 feet was sunk from which 30 tons were shipped, netting \$650 each. At the depth of 175 feet it appears to be a well defined fissure vein from six to 18 inches in width, the ore assaying in this part of the mine from \$200 to \$500 per ton. Considerable work has been done here in winzes and drifts. The vein has widened in places to two feet, and the ore at this (175 feet) level has changed from a chloride to a sulphuret of silver. As further sinking with windlass was impracticable at this point, work has been discontinued pending the erection of hoisting works.

The ore body developed at this end of the mine is 230 feet long, 135 feet deep and from six to 18 inches wide, giving an average for the quartz of \$75 per ton as it comes from the vein. The cost for extracting need not exceed \$6 per ton.

The openings in the east end are still more favorable, showing a vein of ore from 14 inches to four feet, assaying from \$145 to \$292, 40 tons from this quarter having milled \$220 per

ton. Drifting and sinking are being vigorously pushed in this locality, under the superintendence of Frank P. Willard, Esq., a good ore body being already developed here to the depth of 75 feet, the full length of drift as far as it has extended.

The Tiger,

Lying east of the Panther on the same lode, shows a width, where opened, of from four to five feet. Work will soon be resumed both upon it and the Constitution, a neighboring claim and each looked upon as promising. The Beaver, the Black Diamond, the Republic and several others in the vicinity, although at present idle, are also represented as giving flattering prospects. As not more than a half dozen claims are now worked in the entire district and but a comparatively small force on each, Cornucopia may be said to be rather quiet. The Leopard mill is in readiness to start up, and spring is fairly upon them. A much livelier time may be expected.

This is by far the best developed district in northeastern Nevada, and gives the finest indications for permanence and prosperity in the future.

Mr. T. J. Harlan, assayer for the Blue Jacket mill and mine, the property of Mr. Thos. H. Blithe, of your city, reports that the mill started up on the 1st inst., (April,) and has been running on a much higher grade ore than formerly. A pretty fair supply is in sight, and the outlook for the season good. A. C. K.

Montana Quartz Mines.

The Helena *Independent* has a very sensible article on Montana's quartz mines, and raises the question why there is so little bullion produced from the large number of rich lodes throughout the Territory. It is the old story of re-enacted operations, carried on by Eastern capital through inexperienced Superintendents and thoroughly incompetent persons. There are monuments of this species of folly scattered all over the country. Mills have been erected at a cost of hundreds of thousands of dollars where no mines of value existed, simply on the representation of parties who had "feet" to sell. This thing has been done time and again, and the only wonder is that these capitalists should continue to make the same mistakes after once being fooled. The fault is not in the machinery that the mills are not successful, but in the locations chosen and the incompetency of those in charge of them. To a great extent the cause for so many failures in the reduction of ores in this Territory is being overcome. The mills are getting into the hands of competent and energetic men who have lived in the country for years, taking note of the reasons for failure in others and profiting thereby. These men first find out whether there is plenty of ore to be had in the locality chosen before erecting a mill. If the millman has quartz property of his own, he first develops his lead sufficient, at least, to disclose an amount of ore to keep the works supplied for a length of time that will repay the cost of putting up the mill. And this is the true principle to go upon. The old maxim, "be sure you are right, and then go ahead," might be well applied to this subject, by changing the sentence to, "be sure you have the quartz and then put up your mill."

Take the mills of this camp as an illustration of this principle: of the four mills in operation, two were put up by parties owning lead property, with the express intention of treating their own ores. In both instances the owners had previously developed their mines enough to reveal a quantity of ore that would secure them against loss in their construction. Assays and milling tests of the ores were made and the value per ton ascertained, that there might be no cause for failure in this respect. The result is that the Burlington and Davis mills are running steadily, the latter not having shut down, only to clean up its boiler, since starting up three months ago. The yield of bullion is not positively known, further than that the owner seems to be perfectly satisfied, and continues to make improvements in and about the mill, and is pushing developments on his mine rapidly. Not a ton of ore has been crushed except from the Lexington lode. The Burlington mill, erected by Messrs. Young & Roubesh, to treat the ore from their claim on the Burlington lode, has done equally well since the works were completed. They made a couple of trial runs before the mill was wholly finished, and of course, made some stoppages during the time. For the past month, however, the mill has run steadily day and night, crushing from four to five tons every 24 hours, and saving a high per cent. of the assay value of the ore. All of the quartz crushed is taken from one claim on the Burlington lode.

The Dexter or Farlin mill, was built with the original intention of treating the ores from the Travona and Black Chief lodes, the property of Mr. Farlin. Owing to financial embarrassments, however, this mill was completed and started up under the control of W. A. Clark, treating ores of all grades of value and baseness. With what success these works have been run may be judged from the regular shipments of bullion made. Occasional breakages of machinery have occurred, causing short and temporary stoppages, but other than this the mill has been in operation steadily for 10 months. The Centennial mill was put up to do custom work, treating all classes of milling ore

found in this camp, and several lots from outside districts. These works were started and have since been kept in operation under many disadvantages, but have been in the main successful in the treatment of ores. With a few improvements and the financial affairs of the owner properly adjusted, the property would be, and is now, valuable. Owing to some contention between the managers and mine owners, there has been a scarcity of ore recently, but the works are now in operation, and giving fair satisfaction. Referring to the *Independent's* article, we endorse what it says in relation to mill-men and miners working together with harmony, and trust the advice will be heeded. We quote:

At the present time there are a number of really good mills in operation in the Territory and plenty of men who have already learned to treat the various ores in a practical manner, and to the profit of all concerned. It is the duty, therefore, of those who have lodes that can be worked with the outlay of limited capital, to keep these mills supplied with all the ores they can reduce. By doing this, mill-men can and will reduce the price of reduction to about one-half that now charged. They will do so because they can make money at low figures if their mills are kept constantly employed—nothing, if they remain idle half the time. Aside from this, the steady flow of bullion from the country will, in a short time, attract capitalists who are ever on the alert for a good investment, but a few bars every week or two will not have any effect upon them, and the closing of a mill, even temporarily, is bound to have a chilling effect upon any person who may have thoughts of investing in mines or mining machinery. The unceasing clatter of the mills and an uninterrupted flow of bullion, is the only argument that will induce capitalists to seek this remote region for the investment of their surplus funds. Therefore, every person in the Territory should put forth their best exertions to accomplish this object, and not, as is frequently the case, throw obstructions in the way of those who are doing all in their power to develop the country. Mill-men and miners should work together harmoniously, for whenever one prospers the other is certain to do the same.—*Butte Miner*.

ARIZONA.—We had the pleasure of meeting Mr. Dougherty, a very pleasant and well-informed gentleman and an old resident of Pioche, to which town he is now on his way. Mr. Dougherty and party left Pioche for Arizona fifteen months ago with a complete prospecting outfit and have examined the most of the mines in the territory since that time. He gives a very graphic and lucid exposition of its mineral resources, although somewhat skeptical as to the immense wealth that has been generally accredited to it. The party had a very thorough outfit, carrying with them a small chemical laboratory and testing all evidences of mineral deposits. They spent the most of their time in the Chiricahua mountains and have made some very good locations, rejecting anything that assayed under sixty dollars per ton. Mr. Dougherty explains that nothing can be promised as to the future of Arizona, from the fact that all the work done, as yet, is mere scratching on the surface, no mine having been explored to the depth of three hundred feet. If the deposits prove permanent it will be a very rich country, but in its present undeveloped state he is emphatic in his advice to the miner, mechanic and laborer to stay away from there. The most of the mining and manual labor is performed by the Mexicans, who are satisfied with a stipend varying from fifty to seventy-five cents per day.—*Eureka Sentinel*.

MINERAL GROUND IN DISPUTE.—The Loyal Lead mining company, whose property is situated near the town of New Chicago, in that rich mineral region known as the Lava Beds, after putting up a mill and doing some prospecting, quit work, and the ground remained idle for a number of years. Later, when the wealth of the Lava Beds was ascertained by actual working by outside parties, the Loyal Lead owners again figured on the scene, and secured an injunction enjoining the miners from working the ground. They next started work in running a tunnel towards the North Gover claim. A short time only elapsed before the workmen struck a quartz ledge five or six feet wide. And now comes the North Gover owners and claim the ground, commencing suit in the District Court for its possession. Some 50 injunctions were issued and served last week against the Loyal company and unknown claimants, and the place that 10 days back was alive with miners, is to-day silent and deserted, pending the result of litigation.—*Amador Ledger*.

IMPROVEMENT IN CAR SPRINGS.—According to a Newcastle, England, paper, the craft of railway spring makers is threatened with a very serious competition. A new circular spring has been invented; it is made entirely by machinery, and is said to be free from many defects of the present hand-made springs. The new springs are made of solid round bars of steel, highly polished, cut and bent into elliptical forms and bound together in sets to form springs. Four or five bars form the top and bottom of each spring; and it is intended as a further improvement to have a spiral spring, also machine made, to be placed at the centre between the top and bottom set of springs. This would act as a duplicate; in case of accident it would support the entire weight of the carriage.

MECHANICAL PROGRESS.

A New Military Invention.

The German General, Berdan, has devised a new distance calculator, or, in military language, "range-finder." When closed up ready for moving, says *Iron*, it looks like a sort of primitive chariot, mounted on two large light wheels and drawn by one horse. Two men ride upon the comfortable seat, the driver and the operator, and for the latter, so simple is the instrument that no special training is necessary, however desirable it may be that he should also understand the principle of trigonometrical science. When the range of any point is to be taken, before a battery begins to play, for instance, or a regiment to fire, the horse is slipped out of the shafts, and the body of the "chariot" then turned completely over on its axle. The frame, on which is built the seat, then serves as a firm and steady support for the instrument. The body of the vehicle is revealed as a box or case one meter wide, nearly two long and about a foot deep; and when its two opposite ends are thrown open, the instrument is ready for use. This consists, loosely described, of two parallel telescopes, about one and a half meters long, and very powerful, affixed to a frame which swings on a common pivot. The sight ends are just one meter apart, and this, of course, the best line of the calculation. One of these telescopes, the one at the right hand, is movable only with the frame, of which both form a part. This is first sighted on the object, and the frame is made fast, the first step being thus completed. The other telescope is adjustable further, on a pivot of its own, and by means of a small wheel is turned to the right angle of convergence with its companion—that is to say, until it covers the object. Now, having the base line and the angle of convergence, any surveyor could, of course, calculate the distance. But in General Berdan's instrument the wheel which adjusts the second telescope is marked off into meters, centimeters and milimeters, is covered by a little hand or pointer, and when the object is brought within the focus the pointer indicates exactly the distance. This is absolutely all there is of it. In two minutes the instrument can be unlimbered, put into readiness, and a distance found, less time therefore than a gun or battery is made ready. Then the two ends are closed, the body swung around into its place, the horse put into the shafts, the driver and operator mount the box, and away they dash to some other point.

OPPOSITION TO MACHINERY.—We are informed, says *Capital and Labor*, that in an eminent coach-building establishment, a short time ago, the principals desired to introduce an American machine for making the wheels. These, of course, have to be prepared and fitted together with the utmost accuracy; and the machine in question secured this so that any number of wheels could be turned out strictly to gauge. Some of the men engaged in this department were ready enough to work the machine, by which their own labor was lightened, and higher wages were secured to them. But as the use of the machine was contrary to the Trade Union rules, the men were ordered to desist. The machinery was therefore put aside. Since that time wheels made by similar mechanism have been imported from America, this being the only way by which the public requirements for light and strong wheels could be met. It is a curious fact that some of the English carriages exhibited at Philadelphia last year were mounted upon American wheels, which had been sent over from the United States to England, painted, and then returned with the body of the carriage for exhibition. We understand that large numbers of wheels are thus imported, which might have been made in England but for the insensate opposition to the use of machinery.

A BULLET-PROOF CAR.—There has just been completed at the car shops in York, Pa., says the *American Manufacturer*, the first bullet-proof car ever manufactured in the United States. The car is 31 feet long, eight feet high and furnished with all the latest improvements in ventilation, etc. The body below the windows is covered with three-eighth-inch iron manufactured at the Paxton rolling mill, Harrisburg, and the body above them is covered with three-tenth-inch steel. The windows can be closed with steel slides, and when they are shut down the entire car is bullet-proof. The interior is richly ornamented, and in appearance, inside and out, resembles a first-class passenger coach. It weighs about 6,500 pounds and was ordered by the Spanish government for use in Cuba.

WINDMILLS in Holland are about as high as an average church steeple. The arms or fans are of an enormous length, and carry 3,000 feet of canvas. And this is the machine that literally makes Holland. It pumps out the ocean when the ocean gets in. It saws and grinds. It does the lifting and the lowering. A family lives in the mill. In Holland there are full 10,000 of these mammoth structures. Some are built of brick, others of stone, many of wood. They turn slowly, but with great power; and there is seldom a serious or long continued lack of wind.

Iron Railroad Cross-Ties.

An interesting paper on the substitution of iron for wooden cross-ties, by L. S. Weyers, of Brussels, was communicated to the annual meeting of the British Iron and Steel Institute, March, 1877, and published in the *Iron and Coal Trades Review*. The writer gives some details in relation to the practical feasibility of promptly realizing this radical transformation, which, sooner or later, as the forests of the world disappear, will undoubtedly impose itself upon all nations.

He describes several kinds of iron ties that have been suggested, and finally decides upon one possessing these special advantages: 1. It does away with the use of wood in the construction of railroads. 2. It is easy of application everywhere, and can be adapted without special workmen. 3. The rails can be reversed at any time without difficulty. 4. The stability of the rail is great from the number of points of contact which exist between it and the chair. 5. The drainage of the middle track is as perfect as possible. 6. Repairs and renewals are of the easiest and simplest kind. 7. Transportation of material is facilitated, as only one sort of cross-tie is used for either straight or road. 8. The system adapts itself equally well to any section of rail actually in use. 9. Solidarity of parts is obtained without any excess of rigidity. 10. The number of various parts of the appliance is limited to a minimum, as it comprises only one cross-tie, one jawbone chair, two small washers and two bolts. 11. The economy in the laying and maintenance of the track as compared with other systems.

Blasting by Electricity.

The *Colliery Guardian* says: Last week a new phase of mining was introduced at the Houghton main colliery company's extensive works, near Barnsley, where two 15-foot shafts are being sunk in strata, which was yielding a great quantity of water, the greater part of which is now tubbed off. Dynamite is the explosive used here; a number of holes being exploded with the best time fuses at nearly the same time as possible; but the necessity of some more perfect arrangement of simultaneous blasting has long been apparent, the uncertainty of the time fuse even with the most perfect arrangements being very great. It was with this object in view that experiments were made with a new patent electric blasting machine, in connection with Captain Brain's electric fuses, these experiments being conducted by Messrs. F. W. T. Brain and T. Sleeman, on behalf of the Electric Blasting Apparatus Company, Cinderford, Gloucestershire. Most astonishing and successful results were obtained with this simultaneously firing nine holes in the bottom of the shaft, these being arranged in most practical form by Mr. Walker, the colliery company's manager, on a somewhat similar plan to that published by the Electric Blasting Apparatus Company. The output, which from this number of shots fired with the time fuse, had never exceeded 11 tubs, now yielded 47, and all the managers and others who were present concurred in the opinion that the great advantage accruing from the use of this simple apparatus could not be over-estimated. The experiments were witnessed by Mr. Thompson, General Manager of the company, Mr. Walker, the Resident Manager, and other gentlemen interested in mining matters.

RUSSIAN BOUNTY TO HOME MANUFACTURERS.—The *American Manufacturer* says: The Russian government, with a view to the encouragement of native industry, has passed an order that no contracts for railway carriages, locomotives or tenders shall be placed abroad beyond the number of the latter specified in the title deeds of certain companies. Premiums are to be paid to the machinists for the production of locomotives varying from 2,400 roubles to 3,000 roubles, according to the size. These premiums are to be payable for five years, but can only be claimed by firms which produce at least 30 locomotives per annum. During this period the makers will also be allowed to import steel, etc., duty free. The scale of prices for locomotives will be fixed by government, on the basis that the cost price of the Russian machines shall equal the price of similar machines abroad, plus the import duty, the premium not being taken into consideration in the calculation.

MINING THROUGH WATER.—One of the most interesting papers read at the meeting of the Iron and Steel Institute was that on the Chaudron method of piercing water surfaces in order to get at the minerals below them. By an ingenious arrangement of metal casing the effect of something like water-tight compartments is attained, the walls of the shaft are made impervious to the surrounding currents, and access is obtained through the midst of a layer of gravel permeated by water down to the layer beneath, rich in mineral formations.

CENTER DUMP CARS.—The Missouri, Fort Scott and Gulf road contemplate building some iron center dump cars for coal transportation in winter, and grain in summer. When used for the latter purpose they are to have tarpaulin covers. The model of their construction is similar to some cars of this class on the Baltimore and Ohio road.

A BILL has been introduced in the lower house of the Ohio Legislature to compel railroad companies to use self-extinguishing stoves on passenger cars.

SCIENTIFIC PROGRESS.

Origin of the Zodiacal Light.

Prof. Fairchild writes for the *Phrenological Journal* as follows: This vexed astronomical question has been recently reopened by one of our American physicists, who contends that the cone of illumination visible in the advance and recession of the sun, is caused by a section of the earth's atmosphere acting as a tremendous plano-convex lens condensing the solar rays in the form of a pyramid. This cone, as is well known, appears in this latitude most frequently in the spring and fall, when the atmosphere is extremely clear, and may be seen from eight to nine o'clock in the evening, and from three to five in the morning. That it is a phenomenon of solar action, is evident from the fact that its axis is always nearly parallel with a line drawn from the sun's center, in the same manner as the axis of the cone of light produced by a condenser, such as is used for microscope work, is nearly parallel with a line drawn from the light to the point or object illuminated. Its breadth at the base is usually about that of the tropical belt of the earth's atmosphere, and its apparent height is exactly such as would be anticipated under our theorist's view of the case. Of course, the surface of the earth reflects a vast amount of light at all hours in the day, and luminous results of this reflection may be rendered experimentally visible very readily, by observing it against a dark background, which, in the instance of the zodiacal light, is supplied by the shadow of the earth. The reader who is curious to calculate this problem more closely, may remember that the earth's diameter is to the sun's diameter about as 1 to 110, and the sun's diameter to the distance between the two bodies as 1 to 110—an odd coincidence in the figures merely. The length of the shadow cast by the earth at midnight can thus be easily ascertained, since it is simply the axis of an isosceles triangle, the base and angles of which are known. The zodiacal cones of light, one in the east, the other in the west, occupy the base of the conical shadow cast into space by our globe. The reader will readily see how this happens. The earth's atmosphere being about forty miles deep, an oblique section of it, in the form of a huge plano-convex lens, is the seat of all those gorgeous light and color effects that come on just after sunset and just previous to the sun's rising. In addition to prismatic or color effects, due to clouds and to varying densities, the whole atmospheric section transmitting the sun's rays obliquely has, according to our author, an action exactly similar to that illustrated by holding a convex lens near a dark screen, with the axis of the lens presented obliquely to the light. The theory is an ingenious one, and fully accounts for the phenomenon; but on account of a single yet unascertained point, opinion must be for the present suspended. It has been stated, not demonstrated, by spectroscopists, that the zodiacal light is not reflected sun light; and if this statement is verifiable, such an explanation as that just offered is, of course, inadmissible. The proposed new view is, however, so simple and so thoroughly in accord with the ascertained laws of optics, besides offering such a complete exposition of all the phenomena involved in the problem, that one would almost regret to find the statement of the single spectroscopist, who has ever tested the question, verified by subsequent investigation.

MUSICAL SOUNDS IN WOODS.—M. Decharme experimented a short time ago on the musical sounds given by metallic bars of different metals having the same dimensions. He has made similar experiments on different kinds of wood. Notwithstanding the diversity of the kinds of wood examined (38 species and 14 varieties), they were all found to give sounds comprised in the interval of an octave. The most grave sound is m_{14} , given by box; the highest m_{15} , given by Northern fir. M. Decharme gives a list of the sounds emitted by different woods between the two extremes. The range of sounds from the metals extended from 690 vibrations for lead to 2,762 vibrations for aluminum. Sounds from wood are comprised between those for brass, 1303.62, and aluminum, 2762. This is no doubt partly accounted for by the much less range of densities in woods than in metals. Still there are anomalies. Thus, the willow, which, after the poplar and certain firs, was the lightest of the woods experimented on, gives the same note (sol_4) as ebony, which is the heaviest after the the' and the palisander. It was difficult to appreciate the intensity and the duration of the sounds, but palisander, logwood, walnut, acacia were in the front rank in this respect. (The durations of the sounds did not exceed the fraction of a second 0.5, to 0.7, for the most sonorous palisander.) Northern fir and poplar had the clearest timber.

THE FACE OF VENUS.—Mr. Brett has been occupying a good deal of attention lately with a theory that the surface of Venus reflects light specularly, like a polished globe. It is curious that an idea so completely at variance with all the observed facts should have elicited so much discussion. It is easy to show that, if Venus did reflect in this manner, like a thermometer bulb, the image of the sun, which would be formed by the reflection, would be visible only in the most powerful telescopes, if at all.

CURIOUS EXPERIMENTS WITH A RAT'S TAIL.—In a paper read the other day to the French Academy, M. Bert tells how he has been trying to clear up some points in the transmission of excitations along sensitive nerves. The *Journal of Chemistry* says: He takes a young rat, skins a little piece at the end of the tail, and inserts the skinned part into a hole made in the subcutaneous tissue of the animal's back. The connection is completed with the aid of sutures and time, and the rat reconciles itself as best it may to wearing its tail like the handle of a teapot. After eight months the "handle" is cut in two. On pinching the part left in the back, the rat evidently feels pain, and tries to escape. It is thus satisfactorily shown that an excitation has traveled along sensitive nerves in the dorsal part of the tail, in a direction opposite to the normal, those nerves having united with dorsal nerves leading into the spinal cord. This sensibility in the dorsal stump of the tail disappeared in a day or two, and the nerves were found to be in a state of degeneration, owing to separation from their trophic centers. It might have been otherwise, it is thought, had the new connection been prolonged. The experiment, then, is supposed to prove that an excitation at a point of a sensitive nerve is propagated at once in both directions, centrifugal and centripetal; and the same holds probably for motor nerves.

THE TELEPHONE.—There is another claimant in the field for the honor of inventing the telephone. Dr. James Davis of Salisbury, N. C., writes to the *Raleigh Observer*, stating that his "phonetic telegraph," invented ten years ago, anticipated the discoveries of Messrs. Bell, Gray and others. Dr. Davis says that he made pen-and-ink drawings at that time, fully illustrating his invention, and that he described his apparatus to persons whom he names. He declares that his device covered the changing of air vibrations into those of electricity, and restoring the air waves after transmission; that his apparatus was more perfect than that which the present inventors exhibit, and that it could write or register the sounds in a distinct language. Dr. Davis is evidently under the impression that the telephones exhibited have not accomplished the last mentioned fact, but Mr. Gray described an addition for this purpose to his apparatus in the specifications of his English patent, and Prof. Bell is understood to have contrived something of the sort in connection with his sounding diaphragm at the receiving station.

LECTURE EXPERIMENTS.—Two neat and simple lecture experiments are described in foreign journals. F. C. G. Muller, to show that air has weight, proceeds as follows: A small quantity of water is boiled in a flask till the vapor wholly expels the air. A stopper, containing a small tube drawn to a point, is then fitted closely into the flask. The whole contrivance is then placed on a scale and exactly counterbalanced by weights. The lecturer then breaks off the point of the tube and puts the broken pieces back on the scale. By this time the flask is cooled, and as the air rushes in, the scale descends. Victor Meyer illustrates the increase of weight that occurs in combustion by means of a short candle balanced on a scale pan along with the following accessories: a small lamp cylinder surrounds the candle, so close that it will nearly touch its flame. In the cylinder there is a piece of wire gauze, which supports several pieces of caustic soda. The scale is evenly balanced when the candle is lighted, but after burning a while the oxygen absorbed in the formation of sodium carbonate causes the scale to descend.

ANOTHER NEW METAL.—This metal has been named Lavesium by its discoverer, M. Prat, in honor of Lavoisier. In color it resembles silver; it is fusible and malleable. Its crystals are colorless, and its distinctive characteristics, according to M. Prat, are—its silver color, the nature of its spectrum, the solubility of its oxide in ammonia, the peculiar color of its combinations with the ferro-cyanide of potassium, and with sulphureted hydrogen. With the spectroscopic metal gives twenty-three lines, several of which coincide with those of copper, whence M. Prat conjectures that copper may contain the new metal.—*Medical Examiner*.

CHEMICAL RESPIRATOR.—As an improvement upon the numerous respirators hitherto proposed for enabling the wearer to penetrate carbonic oxide, and other gases, left in cellars after explosions of fire-damp, Mr. W. H. Watson, F. C. S., of Beckermest, suggests a respirator containing solution of caustic potash in a tube, as devised by Mitscherlich and modified by De Koninck. Air containing a dangerous proportion of carbonic oxide is fit for respiration after passing through the potash solution. He thinks a valve arrangement might be used, to ensure inspiration of the cleansed air through the mouth, and expiration through the nose.

TRANSIT MEASUREMENTS.—The measurements of the transit of Venus photographs by Prof. Harkness, at Washington, are approaching completion. The reductions of star observations for time and latitude are nearly finished, and in all respects the work is in such a state of progress that it is hoped that the results of the American observations may be published before the end of the year. The work of the English, French, and Germans seems to be nearly in the same stage of forwardness. As to the Russians, we hear nothing yet.

The Society Islands.

We gave a few months ago a view of Tahiti, the largest of the Society Islands, with some notes concerning its soil and productions. We propose at this time to give little views of some of the other islands of the group. Such mention is just now timely from the fact that the first of the season's imports of Tahiti oranges arrived last week, and several cargoes are now due and daily arriving. These little islands, which do us the good service of sending fresh fruits to our markets at the time when our crop is nearly out of the way must possess much interest to all California readers.

The group of the Society islands lies in the South Pacific ocean (lat. 16° 18' S; lon. 148° 155' W), and is formed of two clusters of islands, one of which lies about 70 miles northwest of the other. They were formerly, and by some geographers still are, distinguished by the separate designations of the Society islands proper, and the Tahiti or Georgian islands. The latter are under the French protectorate and the former are independent. The French islands have an area of 453 square miles and a population of about 14,000, of whom 1,000 are immigrants, 400 soldiers and 600 foreign residents. The independent islands have an area of 213 square miles and a population of about 4,000. The islands are all surrounded by belts of coral reefs of various widths and extending from a few yards to five miles from the shores. There are many openings for the passage of canoes, and some large enough to admit ships giving good anchorage inside the reefs. There are small lakes and lagoons in some of the islands and all are watered by numerous streams upon the banks of which, or along the shores,

verdure even to the loftiest summits. The island, surrounded by a reef like Tahiti and others of the group, possesses many ports and good water in abundance. In the interior there is a lake which is navigable, which enables the traveler to explore the island easily. The land lies in slopes and contains many valleys which need only slight culture to be very productive. The mountains rise gently to the north of the island and the foothills are among the most fertile parts of the country. Below these are plains which are bordered by the productive regions. The general soil of the island is vegetable mold mingled with the alluvium washed down from the mountains and abounds in material for plant growth.

Working Low Grade Ores.

In 1875, H. Augustus Taylor & Son, conceived the idea of building a mill, in Georgetown, for the purpose of utilizing the low grade ores of this locality, which had for years been regarded as useless. The idea was not original, for the Terrible company had already demonstrated its feasibility, by erecting a mill and profitably manipulating the low grade ores from its own mine. The Silver Plume concentrating company had also taken steps in the same direction. Taylor & Son secured a desirable mill site in the upper part of Georgetown, just where the south branch of Clear creek comes dashing down through a narrow gorge. The water power secured by them had a fall of 300 feet—200 feet of which is now utilized. The Krom concentrator was selected by them as in their judgment the best machine, and the building and machinery was put up by a man who had the advantage of five years' practical experience in handling the Krom machine. We

Naturally all this raises a dust, and dust is known to contain infinitesimal particles of silver. But the dust is not lost; over each ore bin there is a gigantic pipe with a mammoth hopper turned upside down, and the dust naturally "goes up the spout," landing in a labyrinth of crooked passages, in which a succession of yawning bins are to be passed and into each of which innocent particles of the ore are liable to tumble. These great bins are four in number. The first catches the weighty characters in the confused crowd, the next those of a less substantial cast, and so on, until the poor dust, which escapes through the lattice-work in the tower is about as near worthless as can be.

Since this mill was built about 4,000 tons of nearly worthless rock have been handled, and the valuable ore scattered through it saved. When it began to grind and raise a dust, ore containing 50 ozs. per ton was worth \$3 per ton—it is now worth \$21.

But while this mill did good work, making good wages for itself, and helping the country, there was still a vast accumulation of dust and low grade zinc ore, which, while it contained a large amount of silver in the aggregate, was practically valueless, because none would buy and no process was ready to reduce the worthless truck or extricate the silver.

In this emergency the idea of a leaching mill occurred—a mill which would extract the silver from the low grade ore and make a profit in doing so. To carry out this idea involved an expense equal to that of the great mill already in operation, but the men who compose the Clear company thought they could see through it and did not hesitate.

The Leaching Mill

Stands just below the one above alluded to,

of a syphon, and transferred to the first of a row of eight tubs placed on an inclined plane, or rather steps, six inches high, and is allowed to flow through all, each being supplied by its next neighbor above. In these tubs copper plates are placed, which precipitate the silver, leaving it in a metallic form, ready for melting. There are three additional tubs filled with scrap iron, and here the copper is caught and the liquor passes into a well, from whence it is pumped up into the store-tanks and is ready for use again.

This ends the operation, with the exception of melting the silver, selling the copper as it is, and spending the money.

We should say that tailings, before being dumped in the creek, are thoroughly washed, and any residue of value saved.

This mill is in charge of Mr. S. H. Woodward, and from personal tests made at all the different stages of the operation, we feel satisfied that he is doing good work. He is assisted by eight men, can handle 10 tons of ore per day, and can profitably treat as low as 25-ounce ore. The mill is practically supplied from the waste of the concentrating mill, as the bulk of the ore treated has no market value.

The company also have

Sampling Works

And an ore market attached to the upper mill, and under the charge of Mr. R. G. Seymour.

Mr. W. B. Walters has charge of the

Concentration Department.

And from many years experience in Nevada and here, understands thoroughly the Krom machine. Mr. T. G. Negus has a general supervision of all three of the departments. He is a clear-headed, prudent man, enjoying the con-

VIEWS OF THE SOCIETY ISLANDS.

the inhabitants dwell. There is considerable variety of soil, the sides of the mountains being frequently covered with a thin layer of light earth. The summits of many of the hills have a thick stratum of red ochre or yellow marl, whilst the soil of the level tracts along the shores is a rich alluvial deposit, mixed with vegetable mold and is exceeding fertile. The climate is healthful and very mild, the range of the thermometer being inconsiderable throughout the year. Besides the breadfruit these islands produce almost every tropical vegetable and fruit, including some peculiar to the group. A few fruits and vegetables have been introduced from the temperate zone. The guava shrub, introduced from Norfolk, is now common and bears a profusion of fruit, upon which pigs and cattle feed with avidity. Garden produce is little cultivated and agriculture is very backward. A botanic garden, established by the French, offers seeds to colonists and natives; but there is but little demand for them and prizes offered to stimulate production were withdrawn in 1865 as useless. The spontaneous production of fruits seems sufficient for the natives.

Our illustrations show views of four of the islands as the names beneath the engraving signify. There is of course much uniformity among them all because of their similarity of origin and the remarks above apply to all of the group. The largest of the islands, next to Tahiti or Otaheite, which we described upon a former occasion, is Emeo. Concerning this island we shall add a note, translated from the writings of a French traveler:

The island of Emeo is, if possible, more wonderful in natural beauties and adaptations than Tahiti. To the one who approaches the islands from afar there appear rugged mountains with broken sides, but as one comes nearer the enchantment of the scenery increases. The mountains, of various heights, are mantled with

will not now give an elaborate description of this mill, as it has already appeared in the *Miner*, but merely remarking that it is designed to separate the valuable ore from worthless rock by means of machinery, and that the agent employed is wind instead of water—the specific gravity of the various particles of finely granulated ore acting quite naturally, causing all the good to be gathered into the granary, while the chaff is scattered to the four winds of heaven, or dumped into the creek. A casual glance suggests the following unscientific account, however.

Concentration.

The mill is built with a special view to the economical handling of the ore. The receiving floor is the third, and the work is chiefly done in the two stories below. The ore arriving on wagons or pack animals is dumped on this floor, and is afterwards led into a Blake crusher, passed through an automatic drier and landed in a hopper which feeds a powerful pair of modified Cornish rollers, landing in the basement, whence it is carried in an endless succession of little tin cups attached to a long leather belt, to the very top of the mill—six stories high—landing in a screen, just like an old-fashioned mill bolt. Three other screens exactly similar in shape are located below it, each of which gives a separate size, the general product being four grades of ore, ranging in a granular size from a bird shot down. Now, the ore is ready for the wind work, and all the individual particles start out with nearly equal advantage as to size. Four sets of machines are ready to receive it—each composed of three—two for preliminary and one for final separation.

This ends the process. The clean, valuable, heavy ore finds its way to the lower story, where it is carefully sewed up in canvas bags—and sold. The light, worthless rock and dirt wastes itself in the waters of Clear creek, or is hauled off to make sidewalks or street crossings.

and its machinery is propelled by a part of the same power used to run the upper mill. That is, the great pipe (which, with a diameter of 19 inches at the top and 12 at the bottom, and 200 feet fall, is able to take in nearly the whole creek), is divided and abundance of power supplied to both mills. Besides this another six inch pipe is taken from it for the benefit of the town in case of fire, and this additional pressure enables the Georgetown Water Company to "squirt" over the biggest block, as there is a plug at each corner.

The ore from the concentrating mill is conveyed to the leaching mill by means of a tramway, and is dumped on the drier close by the battery. Ten stamps, each running 120 drops to the minute, soon reduces it to an impalpable powder, and a conveyor and elevator silently deposit it in a big hopper at the top of the mill. On the floor below this there are four smaller hoppers, each immediately above a Bruckner cylinder, and so, by a twist of the wrist, each of these are charged with from 4,000 to 5,000 pounds of ore, and no one hurt. Zinc ore takes from 15 to 20 hours to desulphurize and chloridize. When this has been accomplished the ore is dumped into an iron car, which conveys it to the cooling floor. After cooling it is again taken upstairs by means of an elevator, and is deposited in a large hopper from whence it is taken to the agitators in batches of from 2,400 to 3,000 pounds. The agitator is a large tub, nine feet in diameter and six feet high, and contains 1,200 gallons hot Hunt, Douglas & Stewart liquor (or a modification of that patent medicine), and there it is tumbled about for five or six hours, all the time being kept hot by pipes conveying steam from a boiler in the adjoining room below.

The liquor now holds the silver in solution and the agitator is discharged into a similar tub below, called a settler. From this the clear liquor containing the silver is drawn by means

fidence of the company and the esteem of the general public. Mr. F. M. Taylor is commander-in-chief, and while he has a difficult task to perform, he seems to be perfectly master of the situation. Each of the three separate departments he keeps separate and distinct from the others. The concentrating mill is charged with all the ore it receives, and credited with what it prepares for market. Every ounce of silver which goes to the leaching mill is properly charged, and the bullion produced placed to its credit; so, also, with the sampling works.

The Clear Creek company have been a benefit to our town and a credit to the district. They have spent \$115,000 in building, and have given constant employment to a good many men. —*Colorado Miner*.

A NEW FRUIT SHIPPING COMPANY. —*The Call* says: "The newly organized Western Refrigerator Car Company, of San Francisco has elected the following officers: A. T. Spotts, President, Robert Williamson, Vice President; Bank of California, Treasurer; Bernard Lane, Secretary. Two cars belonging to the company, may be seen at the railroad depot, on Townsend street. They differ somewhat from those used by the Grangers. The shell of the car is about six inches thick. There then is an inch of felt lining, and, in addition, a four-inch padding of charcoal and an inner envelope of galvanized iron. The ventilation is through the roof, and it can be regulated at will. The ice-box is suspended and so arranged that air cannot enter to thaw the contents. Each chest has a capacity of one ton, enough for four days' service, and the temperature maintained ranges from 34° to 40°. One of the cars, grape-laden, was dispatched from Sacramento on 27th of Oct. last, and arrived in St. Louis, its destination, on 2d of Nov. Fruit was allowed to remain in the car until Dec. 7th, and when taken out was in as good condition as if newly taken from the vine."

Oil Fuels.

The discovery of large petroleum supplies on this coast render plans for turning it to practical account of wide interest. At a recent meeting of the Scientific and Mechanical Society, at Manchester, England, a paper on the "Combustion of Oils for the Generation of Steam," was read by Mr. Wm. Gadd, who said: "My special object is to describe to you an apparatus, which I believe successfully accomplishes the purpose, and from the use of which I hope to render the combustion of oils for the generation of steam a practical reality."

"The means employed in this method are of almost the simplest character possible, and consist of, first, an open vessel, by preference flat shaped, composed of fire-clay, or any other suitable material, which is placed upon, and covers, the fire-bars in an ordinary furnace. In and upon this vessel are formed projections, of a conical or other shape, as many as are found to be necessary; which projections have holes passing completely through them, so as to allow of a free passage of atmosphere for the supporting of combustion in all parts of the fire or flame. A range of steam pipes of small dimensions (half-inch gas pipes are quite sufficient) is laid along the bottom of this vessel, having fine holes pierced therein, at the required intervals, for the emission of numerous small jets of steam. This range of pipes is put in communication with the boiler, and regulated by means of a valve or stop tap. Another pipe is in communication with the cistern or reservoir of oil, and another with the water supply. The oil supply is made self-acting by means of a ball tap, which gives at once mechanical stocking of the simplest and most perfect character possible."

"Upon proceeding to start this apparatus, I first let into the vessel a little water, and then as much oil as will nearly bring the liquid to the top of the range of steam pipes, or, in other words, to the depth of three-eighths or half an inch, but either a greater or less depth will act about equally as well. I then light the oil, and when it is fairly started I turn on the steam; and according to the force and quantity will be the intensity of the flame produced, giving a very perfect combustion at all pressures. Of course, in starting a boiler when cold, it becomes necessary to borrow steam from another boiler for a short time, or to raise a few pounds of steam at the expense of a little smoke. The use of the water, which to some may seem strange, is of great service with the very heavy hydro-carbons, in assisting to produce perfect combustion, and act, as far so I can ascertain from prolonged observation and thought, in this way. The oil being the heaviest substance the water rises to the top, and thus retards the combustion of the oil, until it escapes through the water in the form of gas, or at any rate, until it assumes a much lighter form than it originally had; furthermore, the constant influx of atmosphere to all parts of the flame, produced by the action of the steam, has such a cooling effect on the surface of the liquid as to prevent the same from boiling, no matter how hot it is above. The retardation, I believe, assists very much the economical consumption of the fuel. But with some oils the water is not needed. In fact, the particular details of this method may be varied according to the character of the oils desired to be used. Thus I find it capable of adaptation to the light, as well as the heavy hydro-carbons."

A SALT MINING EXPERIMENT.—The *Reese River Revueille* says that the mining of salt from Spalding's salt marsh, in Smoky valley, will have taken a new departure, if an experiment now in progress proves successful. The salt is deposited on the surface of the marsh by evaporation, it is supposed. There is no water on the surface of the marsh, but at a depth of about four feet the saline water exists, and in the spring of the year the salt forms on the surface in a thin scale, which, being removed, another scale soon forms. The obtaining of the salt by waiting for the formation of these crusts is necessarily slow and tedious, and only admits of a yield of salt during the spring and summer months; and to obviate this, so that salt can be obtained at all seasons, the experiment is being tried. Several hundred feet distant from the salt marsh, there is a flat surface of clay that will hold water, and on this a boiler and pump have been set up. The pump is connected by an iron pipe with a reservoir dug in the marsh, the said reservoir being fed by ditches dug in the marsh to the level of the saline water. From the reservoir and through the pipe it is proposed to pump the water into the clay-bottomed receptacle, and there allow it to evaporate; and it is thought that the salt can thus be obtained much more cheaply and expeditiously than by the slow process heretofore employed.

SULPHUR CREEK MINES.—A Sulphur creek correspondent says: The Manzanita gold mine has been incorporated, and is at present reducing number one ore. There has been considerable prospecting going on lately. Tucker & Golding have taken up a claim, and are doing better than they expected. Wm. McCune has also located a claim on the old Sulphur works ground, and has good prospects. Wm. Cherry cleaned up his sluice boxes last Saturday, and netted in amalgam about \$200 for one week's sluicing. Considerable excitement is shown among the old settlers on the creek. Time will show that we have been working over good mines, not knowing their value.—*Columbia Sun.*

USEFUL INFORMATION.

Hints to Firemen.

The *Mechanical Journal* notes some good points in firing for steam boilers, which, although they may not strike the reader as new, may be of assistance to some amateur stokers: "An engineer should allow his fire to burn gradually when commencing to get up steam from cold water, as, by allowing the fuel to burn very rapidly some parts of the boiler become expanded to their utmost limits while other parts are nearly cold. Of course a great deal depends upon the time in which he has to raise his steam. An engineer should regulate his fire at a uniform thickness, and not allow any bare places or accumulations of ashes or dead coals in the corners of the furnace, as these places admit great quantities of cold air into the furnace and render the combustion very imperfect. An engineer should avoid excessive firing as much as possible, as it is attended with more or less danger, because the intense heat repels the water from the surface of the iron and allows the boiler to be burned. He should keep about three inches of anthracite coal and about five inches of soft coal on his fires, but he should regulate the thickness of the fire according to the capacity of the boiler. If the boiler is too small for the engine the fire should be kept thin, the coal supplied in small quantities and distributed evenly over the grate, and the grate kept as free as possible from ashes and cinders; but if the boiler is extra large for the engine, the thickness of the fire makes but little difference. If the fire becomes very low, he should neither poke nor disturb it, as that would have a tendency to put it entirely out; but he should place shavings, sawdust, wood or greasy waste on the bare places, with a thin covering of coal; then, by opening the draft to its full extent, the fire will soon come up. If it should become necessary to burn wood on a coal fire, it is always best to make an opening through the coal to the grate bars, so that the air from the bottom of the furnace can act directly on the wood and increase the combustion. He should give great attention to the regulation of the draft in the furnace, as it is one of the most important parts of an engineer's duties, for in fact it is next in importance to the regulation of the water in the boiler."

American Pottery.

The report of the Centennial Committee appointed by the United States Pottery Association contains some very pertinent observations, of which the following are selections:

It was remarked by many that no industry had made more rapid strides than American pottery, comparatively a new one in this country, and it will henceforth rank favorably with other manufacturing industries, and especially be looked upon as the most interesting of all. The porcelain exhibited by the Union porcelain works has been thoroughly tested and closely compared with French and German manufactures, and it has been conceded that the quality of this ware is not excelled by any, and second to none. The same is the case with stone china or white granite, and it may be safely stated that you have proven your ware to be superior to the English, so far as quality and color is concerned. Shapes also are, as a general thing, more uniform and suitable for the American market. The value of the display no one can estimate at present. This, however, is certain, no potter need hereafter sail under false colors, but proudly choose his own trade mark of American design. Agents of English potteries admit freely that the display of American crockery has damaged their trade considerably. Dealers generally becoming posted on this class of goods and knowing that at any time they can replenish their stocks, it is difficult to obtain orders for importation in advance. The ware has kept pretty free from crazing, and, with the exception of some cracked ware, an imitation of the celebrated Satsuma ware, and taken in mistake for crazed ware, stood the test well, and the jury on ceramics were obliged to change their views in reference to this matter. The Secretary at the same time took the liberty of exposing to the jury on ceramics crazed pieces of ware from all the leading potteries in England, thus proving that no manufacturer can prevent wares from crazing occasionally.

Artificial Ivory.

Two parts of caoutchouc are dissolved in 36 parts of chloroform, and the solution is saturated with pure ammonia gas. The chloroform is then distilled off at a temperature of 85° C. The residuum is mixed with phosphate of lime or carbonate of zinc, pressed in a mold and dried. When the phosphate of lime is used, the product possesses the nature of the natural ivory; this composition possesses the proper proportions of lime and of phosphate, and the caoutchouc takes the place of the organic material of the ivory; the other parts of the natural product are of little importance.

Our contemporary, *Les Mondes*, speaks of an artificial ivory manufactured in France, by M. Dupre, who uses simply a paste of papier mache and gelatine. Billiard balls composed of this material are much cheaper than those of ivory, and are sufficiently hard and elastic to with-

stand the most severe blow of the cue. They can be dropped from the top of a house, or struck with a hammer, without breaking. This same material can be used for many other purposes. Stucco work of the most complicated design, and the capitals of columns made of this material, can be colored to imitate the most precious marbles.—*La Nature.*

Influence of Pressure on Combustion.

M. Wartha has observed the burning of six stearine candles in free air, and in an iron case under a pressure of 1.95 atmospheres. They burned under this pressure with a flame nine to twelve cm. long, and gave much smoke; their luminous power diminished, while the flame assumed a yellowish-red color. The decrease of weight after one hour of burning was found to be less than in burning in free air. This last result is opposed to the observations of Frankland, who has affirmed that the consumption of the burning material of a candle, or the like, is not perceptibly dependent on the pressure of the medium in which the combustion occurs. It is supposed that the difference of pressure in Frankland's experiments (on Mount Blanc and at Chamouny) was not sufficiently great to give a distinct difference in consumption of the burning matter. M. Wartha further put a candle to burn under an air pump receiver, with special apertures, and, with increasing rarefaction, the flame was seen to enlarge, and its luminous power to diminish. At a pressure of 90 cm., the greatest rarefaction produced, the luminous power was quite gone, and the flame, which now assumed three-fold size, appeared to consist of three parts, an inner bluish-green cone with a violet sheath, and a weakly violet mantle. The diminution of the luminous power in this case M. Wartha explains by the fact that under less pressure less of the products of combustion are separated in the form of soot.—*Nature.*

A FRENCH INDUSTRY.—A peculiar industry has recently come to grief in Paris. An establishment was organized for the purpose of breeding maggots. The means by which the "god, kissing carrion" was encouraged in the process were very simple. Over the soil there were spread large quantities of stale fish, dead lobsters, odoriferous poultry, and other refuse of the markets, as much as half a ton of large fish being taken on the premises in a single day. This stuff was soon attacked by the maggots, which in turn were carefully picked out and packed in casks of galvanized iron, and finally were sold for fish bait and chicken feed. The remaining refuse was converted into manure. It may well be supposed that the neighbors objected to the smells from the establishment. Moreover, the production of maggots was not confined to the premises; the flies roamed around and deposited the larvae upon any exposed food in the vicinity. There was a little doubt as to whether the flies came within the scope of the sanitary laws, but at last the authorities ordered in the police and stopped the manufacture.

GOOD HEALTH.

Diseases Spread by Tailors.

We read in an English exchange that the other day a delegation from the Amalgamated Society of Tailors waited upon the British government in the person of Under Secretary Cross. Their object was to lay before him some facts in connection with what was called the "sweating system." One of the delegation said he had seen instances in which garments were lying on a bed in which fever patients were suffering. There were a great many instances in which such things had taken place. They considered that if an employer got people to take work home, he should be bound to get the place to which it was taken registered, and hoped Mr. Cross could see his way clear to make it imperative that every house used as a tailor's workshop should be so registered by the employer. A delegate from Manchester gave the results of visits to 1,000 homes where this work was carried on, and stated that the condition of things was something deplorable. In some cases four or five persons were in a room nine feet by 12 feet. Sometimes people were making these garments in the midst of their domestic arrangements. From the facts that had come under his knowledge, he had no hesitation in saying that the state of things required alteration, and that the people engaged were in a most unhealthy condition. They found somewhere near 1,300 people engaged in this way, and all the surroundings of the place were such as would foster and spread disease. Another delegate said in some instances in London a man and woman would be at work in a small room at the top of a house in which they lived and slept. This people occupied in this were so crowded together that the places could not fail to foster and spread disease. While people went to large shops with showy fronts, they did not know that the clothes they purchased were made in close and unhealthy rooms. He knew a case in which, while the body of a child, who had died from small-pox, lay dead on the table, and two other children lay sick with the disease; the man and wife were at work in the same room, and 12 fashionable coats were in the room, which would be sent all over the town. Mr. Cross said he would introduce a bill after Easter to cover the case.

Mental Influences on Health.

Novice writes to the *Phrenological Journal* as follows: Probably there is no hygienic means that has a greater sanitary influence than that of a cheerful and well-tempered mind; and perhaps nothing exhausts the vital energies and disorders the bodily functions so effectually as a fretful and irritable mentality. Let the passions be our servants, and it is well; but let them be our masters, and they will not only rule, but ruin us. The moral and intellectual faculties have a powerful sustaining and preserving influence over the life forces. All who have ever felt the holy influence of love, and the blighting tendency of hatred, cannot fail to appreciate this part of our subject. The passions should be regulated and controlled. They are not to be abhorred, nor an attempt made to annihilate them. There is no faculty or propensity given us that will not contribute to our good when properly used. The use of every human endowment is good; their abuse is evil. A reasonable exercise of the emotions has a beneficial effect. Fame, wealth and power, may honorably command our aspirations. When such is the case, the exertion of the mind and exercise of the body necessary for their attainment are generally rewarded with energy, spirit and health. Let it be known that the legitimate use of all our powers, whether of body or of mind, is conducive not only to our health, but also to our highest good.

Those who have been blessed with health almost all of their lives may think the regard enjoined here to special precautions and directions is puerile. But if health is maintained, a good of the highest value is secured.

Health is the instrument by which wealth, intellectual culture, and fame are attained; the essential to any positive and beneficial work. Health is the chain that unites us to friends, and makes our companionship a source of pleasure and profit. Health enables us to meet the ills, trials, and disappointments of life with fortitude and serenity; to worry not over the past, but to improve the living present with zeal and earnestness. Health enables us to be useful and happy.

With such incentives to the maintenance of health, surely none but the indifferent would be careless in respect to the employment of those means that are likely to guard them against sickness.

Cold Feet.

Cold feet usually result from unequal circulation. The *Phrenological Journal* gives the following hints for avoiding them:

The feet should be washed in tepid water every day or two; but do not put them into water so hot as to make them tender. In concluding the bath, dip them into quite cold water, which closes the pores naturally, and then wipe and rub them entirely dry and warm.

Wear broad, heavy-soled, capacious boots with a loose insole. The foot appears smaller and more genteel in a boot quite large for it than in one in which the compression compels the sides to over-jut the sole and look tight over the instep or toes. Ladies should remember this fact, which is so well known to fashionable shoemakers. A stylish dealer was lately complimented about his small feet and nicely-fitting boots; a compliment which his wife also shared among her lady friends. The secret was they never pinched his feet. He wore number eight, while his wife wore the unpopular size of five. He could put on a six or his wife a four or perhaps a three. By wearing boots of the form of their feet, of ample size, the boots remained in graceful shape. The gentleman's boots were nearly number nines in length, to lend proportion, and add comfort in walking.

Change your boots often. In use they absorb moisture from within and without and by frequent change and drying will be much warmer. If you have not two pairs, remove the insoles and dry them thoroughly with the boots each night. The patent-covered cork insole is a nice thing for those who can afford them, if they do not sweat the feet. But the smooth, stiff-leather insole is the best for all people, and one good pair will wear out several pairs of boots.

If your feet sweat easily and then chill from the dampness, wear light cotton stockings with your wool socks over them. Just try this expedient and see how nice and warm your feet feel. Ladies who ride will find a large pair of socks, over shoe and all, a great comfort.

FRAUDS IN OPIUM ANTIDOTES.—The opium antidote business has been sharply called upon to halt by the Cumberland Medical Society, of Maine. They have caused a quantitative analysis of certain of these nostrums to be made, and report the results widely among the profession. One specimen, manufactured by Mrs. J. A. Drollinger, of La Porte, Indiana, was analyzed by Walz & Stillwell, New York City, who found it to consist of glycerine, colored with aniline red, and to contain in solution 1.383% by weight of the sulphate of morphia—about seven grains to the ounce. The second was the preparation of "Dr. S. B. Collins; the great Narcologist of the Age," also of La Porte. The analysis of this was made by Dr. Henry Carmichael, Assayer of the State of Maine, and differed from the preceding only in the amount of the sulphate of morphia shown to be present, namely, 3.2%. A teaspoonful (a dose frequently prescribed by the proprietor), would contain almost two grains of morphia—nearly 12 times the ordinary medicinal dose.

WE ARE FOR THE MINING AND SCIENTIFIC PRESS. We invite
 not only professional men, but practical miners and me-
 chanics to contribute to our columns. All communica-
 tions will be kindly treated. Authors, as well as readers,
 will be benefited by corresponding.

Address all letters to the firm, and not to individual
 members, or others, who may at any time be absent from
 our office.

Our latest forms go to press on Thursday evening.

SAN FRANCISCO:
 Saturday Morning, May 5, 1877.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Walker's Compound
 Steam Pump; Mining Suit; Decision in the Emma Mine
 Suit; The "Mining and Scientific Press," 274. Large
 Fees for Lawyers; Items of Interest from the Mines;
 Gold and Quicksilver, 280. Early History of the Eastern
 Slope.—No. 6, 280-81. An Improvement in Tele-
 graphy, 281. Mechanical Ore Concentration and Sepa-
 ration.—No. 24, 284.

ILLUSTRATIONS.—Section of Walker's Compound
 Steam Pump; Special Compound Steam Plunger Pump
 for Underground Work, 273. Views of the Society
 Islands, 278. Improved District Telegraph Signal Box,
 281.

CORRESPONDENCE.—Mining in Elko County,
 Nevada, 274. Testing Base Metal Ores, 294.

MECHANICAL PROGRESS.—A Military Inven-
 tion; Opposition to Machinery: A Bullet-Proof Car;
 Iron Railroad Cross-Ties; Blasting by Electricity; Rus-
 sian Bounty to Home Manufacturers; Mining Through
 Water; Center Dump Cars, 275.

SCIENTIFIC PROGRESS.—Origin of the Zodiacal
 Light; Musical Sounds in Woods; The Face of Venus;
 Curious Experiments with a Rat's Tail; The Telephone;
 Lecture Experiments; Another New Metal; Chemical
 Aspiration; Transit Measurements, 275.

MINING STOCK MARKET.—Sales at the San
 Francisco, Pacific and California Stock Boards; Notices
 of Assessments, Meetings and Dividends; Review of the
 Stock Market for the Week, 276.

MINING SUMMARY from the various counties in
 California, Nevada, Arizona, Colorado, Idaho and Mon-
 tana, 277-84.

USEFUL INFORMATION.—Hints to Firemen;
 American Pottery; Artificial Ivory; Influence of Pres-
 sure on Combustion; A French Industry, 279.

GOOD HEALTH.—Diseases Spread by Tailors; Men-
 tal Influences on Health; Cold Feet; Frauds in Opium
 Antidotes, 279.

GENERAL NEWS ITEMS on page 285 and other
 pages.

MISCELLANEOUS.—Montana Quartz Mines;
 Arizona; Mineral Ground in Dispute; Improvements in
 Car Springs, 275. The Society Islands; Working Low
 Grade Ores; A New Shipping Company, 278. Oil Fu-
 els; A Salt Mining Experiment; Sulphur Creek Mines,
 279. The Summer Mine; New Laws for Homestead
 Entries; Refrigerator Shipments, 282. New Incorpora-
 tions, 284.

NEW ADVERTISEMENTS.

Assessment Notices—Empire Mining Company; Booth
 Gold Mining Company; Hygienic Medical Institute, S.
 F.; The Giant Powder Company, Bandmann, Nielson &
 Company, S. F.

SOUTHERN PACIFIC RAILROAD.—The comple-
 tion of the Southern Pacific railroad to the Colo-
 rado river, is announced from the General
 Superintendent's office. The following new
 stations are specified. The last two are not
 yet opened. Frink's Spring, distant from San
 Francisco 641.8 miles; Flowing Well, distant
 from San Francisco, 658.5 miles; Pilot Knob, 710
 miles from San Francisco; Colorado River, Cal.,
 718.2 miles from San Francisco; Yuma, Arizona,
 719.2 miles from San Francisco. Yuma will be
 opened early in May, as a regular agency sta-
 tion, and will then become, until further notice,
 the terminal or connecting station for prominent
 points in Arizona and New Mexico. The daily
 trains with sleeping cars attached, will make
 the following time: Leaving San Francisco at 4
 P. M.; leaving Sacramento at 10:45 A. M.; leav-
 ing Lathrop at 8:15 P. M.; arrive at the "Loop"
 (next day) at 7:15 A. M.; arrive at Los Angeles
 (next day) at 1:55 P. M.; leave Los Angeles
 (next day) at 2:25 P. M.; arrive at Colton (next
 day) at 6:10 P. M.; arrive at Pilot Knob (second
 day) at 6:25 A. M.

BULLION SHIPMENTS.—Since our last issue
 shipments of bullion from prominent mines have
 been as follows: Manhattan, April 24th, \$18,-
 665.84; Con. Virginia, 26th, \$140,623.16;
 Northern Belle, 24th, \$5,107.25; Comanche,
 24th, \$8,522.67; California, 26th, \$215,923.07—
 total to date, \$1,215,991.34; Northern Belle,
 26th, \$8,953.82; California, 28th, \$101,442.58
 —total to date, \$1,317,433.92; Con. Virginia,
 28th, \$93,778.27—total to date, \$601,330.54;
 Tybo Con., 26th, \$15,190.37—total to date,
 \$84,356.39; Modoc, 27th, \$5,948.80—total to
 date, \$76,635; Northern Belle, 29th, \$11,255.-
 16; California, May 1st, \$241,288.52; total for
 April account, \$1,558,722.44; Tybo Con., 30th,
 \$6,794.91; total to date, \$93,151.30.

Large Fees for Lawyers

The St. Louis *Globe* says: "In the Dancer
 will case there are said to be 80 lawyers, and
 \$450,000 to fight over. This is only \$15,000 to
 each lawyer. The Bar Association should protest."

This sarcastic paragraph will be appreciated
 by nearly everybody except the lawyers them-
 selves. It has become so much the custom to
 charge heavy fees in cases of any importance,
 that lawyers of very limited ability have the as-
 surance to place their services at outrageous
 figures in every case where a large amount is
 involved. In contested will cases in particular
 the practice has become so notorious that peo-
 ple always expect to be mulcted of a large sum,
 and executors consider it necessary or expedient
 to take a good slice of the estate either for a
 compromise or to defend it. In either case the
 lawyers get the larger share, and the heirs are
 more or less at the mercy of the legal fraternity.

The principle, pretty well agreed upon among
 lawyers, that the fees should be in proportion
 to the value of the property involved, rather
 than to the extent or value of services rendered,
 is a very bad one, and calculated to bring dis-
 grace upon the profession. In a recent promi-
 nent suit in this city, the witnesses for a law-
 yer who charged an exorbitant fee, all lawyers
 themselves, seemed to agree in the principle
 mentioned, although the community at large
 held a very different view of the subject. The
 idea that a man must have half or two-thirds of
 a large estate simply because he is agent for a
 client who claims it is preposterous. These cir-
 cumstances have happened so frequently of late,
 however, that people are getting their eyes open
 to the abuse with a view to remedy it. People
 who employ lawyers in cases where large prop-
 erty is involved, will do well to have written
 agreements as to fees before anything is done,
 and refuse peremptorily to accede to any exor-
 bitant demands, out of proportion to the services
 rendered.

In the legal profession of course considerable
 study and practice is necessary, and to be a
 good lawyer even the most brilliant intellect
 must have special training and extended prac-
 tice; so that good lawyers expect good pay.
 Still this is no excuse for charging extortionate
 fees. People in other professions and trades
 also require special training and study, but the
 compensation in no other profession equals that
 expected, and often received, by the legal fran-
 ternity. The abuses in this direction, for a long
 time tolerated, call for speedy remedy, and if
 not corrected by the more far-seeing of the pro-
 fession must be by the people themselves. It
 is hardly worth while for a man to work hard
 and accumulate wealth for certain persons, and
 have it distributed around at his death among
 a lot of lawyers who he never saw or heard of.

To some extent it is the fault of the people
 themselves that such heavy fees are paid, as
 when contesting a will, for instance, people are
 willing to pay pretty heavily to get even a
 small share, especially as such cases are fre-
 quently taken on a contingent fee—that is, they
 get nothing unless they win.

If persons who had disputes would submit to
 arbitration instead of going to law, they would
 be better off in nine cases out of ten. Get one,
 two or three fair-minded men to listen to the
 cause of grievance on both sides and let them
 decide. The only trouble about this is that those
 who lose are apt to want to go to law
 afterwards; but if a written agreement not to
 do so were drawn up in the first place this could
 be obviated.

Again, people disputing over property can
 sometimes come to an understanding among
 themselves if the right spirit is manifested. A
 case of this kind occurred in Colorado last week.
 An old discovery on Red Elephant mountain
 owned by Gen. Marshall and others, was taken
 possession of by Wheeler, Thomson and others,
 under the jumping law, about three months
 ago, and worked steadily up to the present
 time. A large body of valuable mineral having
 recently been found in the mine, and great ex-
 citement following, the contending parties were
 in imminent danger of coming to blows, each
 claiming the title to the entire property. On
 the 16th ult., however, the parties in ques-
 tion met and agreed upon an equitable division
 of the property, thus dispensing with pistols,
 lawyers or courts, and involving no expense
 whatever.

DEPARTED.—John Newstead, who died of
 consumption, near Fruitvale, April 26th, com-
 menced the printing trade in this office at the
 age of 12 years, in 1867. He was an intelligent,
 active and faithful lad. Employers and fellow-
 workmen universally esteemed him for his good
 conduct, and all sincerely regret his early de-
 mise. His kind and manly virtues will long
 remain in our memory.

PERSONAL.—Wm. J. Lawrie (or his alias).
 Description—American, probably of Irish pa-
 rentage; age, 25 or 26; height, about five feet
 six inches; weight, about 130 pounds; complex-
 ion dark; hair black and small dark mustache.
 Was in Marin and Sonoma counties last Febru-
 ary. Information of his whereabouts wanted
 by Dewey & Co., San Francisco.

Items of Interest from the Mines.

We give below items of interest from promi-
 nent mines, most of which are collated from
 letters of the respective Superintendents on file
 at the offices in this city:

The last clean-up of the Eureka (G. V.) was
 325 ounces of amalgam.

In the Eureka Consolidated the ninth level
 drift has been extended west 39 feet, and is now
 193 feet from Bell shaft, and looks very well in
 face of drift, with very good indications of ore.
 The seventh level prospects continue about the
 same, bunches of ore showing along the drift.

The stopes above the 650-foot south level of
 the Comanche are getting small and will not
 yield much ore; the 450-foot north level is more
 favorable for ore.

The ore stopes in the California are all look-
 ing well and yielding very rich ore.

On the 1650-foot level of the Con. Virginia
 the stopes are yielding rich ore.

On the 1150-foot level of the Utah they have
 explored the west drift a distance of 407 feet
 from the shaft, and find nothing but hard rocky
 formation. Work is now suspended in this west
 drift.

Mr. W. Williams, formerly connected with
 the Ophir, is now Superintendent of the Defrees
 mine. He has made an estimate of the amount
 of ore in sight in the stopes from the level sev-
 enty-three feet below the tunnel level to sur-
 face; that level being opened up on the lead
 349 feet in length. Allowing fifteen cubic feet
 to the ton the estimate shows over 6,000 tons
 above that level, the ore assaying \$125 to \$300
 per ton. Another level will be opened as soon
 as hoisting machinery (already ordered) can be
 got ready to work. The shaft is now 63 feet
 below the present level, but owing to the
 pressure of considerable water work has been
 suspended upon it pending the arrival of the
 machinery. This mine is about 1,000 feet from
 the Grand Prize, and now has about 600 tons of
 assorted ore in the dump, besides a quantity of
 unsorted ore.

The Justice is shipping the usual amount of
 ore to the mill.

The Martin White M. Co. have got out of
 their financial difficulties and an entire reorgan-
 ization of the company has taken place. Tues-
 day the following officers and Trustees were
 elected: President, Annis Merrill; Treasurer,
 George C. Hickox; Superintendent, John Hooper;
 Secretary, Lytleton Price. Trustees—C.
 H. Stanyan, John A. Hooper, E. D. Sawyer,
 Annis Merrill, and one vacancy to fill. Martin
 White, the former President and chief manager,
 and L. G. Clement, the Superintendent, are the
 principal retirements. It is stated that the
 new Board of Trustees have paid all the indebted-
 ness against the company, and work is to be
 immediately resumed at the mine. The 1,000
 shares of the stock sold Wednesday at auction
 brought from \$6 to \$9 per share.

Gold and Quicksilver.

We were shown this week, by Mr. Geo. S.
 Spratt, Secretary of the Manzanita gold mining
 company some very curious ore from the mine.
 One of the pieces was very rich in free gold
 which occurs in a narrow seam of quartz, run-
 ning through the piece of slate. It also con-
 tained some sulphurets. The other specimen is
 unique and is a mineral curiosity. It seems a
 mixture of quartz and slate with specks of free
 gold and quantities of sulphurets. Along one
 side is a streak of cinnabar, almost pure "ver-
 milion," which is probably 80 per cent. quick-
 silver. This combination is a most unusual one,
 but is convenient from a mining point of view.

Although very rich in gold, if the price of
 quicksilver was high the owners would work the
 vein as a quicksilver mine; but as it is, they
 work it for gold, and a quantity has turned out
 at the mill \$42 per ton, although single assays
 run into the thousands.

The ore which is richest in quicksilver is
 selected and retorted first to obtain the mer-
 cury and is then milled for gold. The com-
 pany buy no quicksilver as they obtain all they
 want for milling purposes from the rock itself.

The mine from which this curious ore comes
 is in Sulphur Creek district, Colusa county, 25
 miles from Williams station, the end of the
 railroad running from Davisville. The country
 rock is limestone and the ledge is composed of
 talco-slate formation, interspersed with fre-
 quent veins and feeders of quartz, charged with
 alternate seams of rich sulphurets. The mine
 has been known as a gold mine for nearly 15
 years, and at that time considerable quantities
 of gold were washed from the creek which passes
 the ledge at its base, but only small amounts
 of the rock were worked prior to the undertak-
 ing of the present company in October, 1876, at
 which time they commenced operations with a
 force of 20 men and have during the time ex-
 tracted a large amount of ore. The ledge mat-
 ter is 40 feet in width where cut by the tunnel
 at a depth of 140 feet.

There is on the property a new ten-stamp
 mill, supplied with Hendy's Challenge feeder,
 etc. A Stevenson pan and settler is now being
 shipped. They have crushed, so far, about
 2,000 tons of the rock, which have yielded well.
 The Board of Directors of this company are
 George Grant, Joshua Hendy, George Senn,
 John C. Sanderling, and George S. Spratt.

Early History of the Eastern Slope—No. 6.

Orion Clemens and "His Brother Sam."

As already stated, Orion Clemens had been
 appointed Secretary of the Territory of Nevada,
 having for assistant his brother Samuel, since
 better known as "Mark Twain." These broth-
 ers hailed from Missouri, and came out with
 Governor Nye, forming part of a numerous retin-
 e wherewith that gentleman arrived in Carson
 City, capital of the Territory, in the month of
 July, 1861. Entering the town in a body, costumed
 after the Eastern style, this party of officials,
 semi-officials and expectants attracted a good deal
 of notice; the article in their make-up that soonest
 arrested the attention of the older residents and
 most conclusively pointed to their recent arrival
 from a land more advanced in the properties, or
 at least in the matter of "loud" head-gear, was
 the stiff and towering plug hat, with which every
 single scone was ornamented. Such a spectacle
 having never before been seen over there, these
 outre hats soon became the common jeer of the
 town; which, the new comers perceiving, were
 not long in supplanting by a title more conform-
 able with the tastes and costumes of the "East-
 ern Slopers."

As there is nothing connected with the adorn-
 ment of his person in which the average Indian
 finds more delectation than in this style of hat,
 with its gloss and glue, it was the wont of the
 Piute braves, who made Carson City their cen-
 tral loafing point, to eagerly seize and appropri-
 ate these discarded "stove-pipes" the instant
 the Israelitish trader had cast them into the
 street, and then for a time thereafter these dig-
 nified fellows were to be seen wearing one, and,
 when successful at poker, perhaps two of these
 remarkable fabrics, from the top of which there
 invariably protruded a great shock of bristling
 black hair—it being the practice of these peo-
 ple, as soon as they get hold of one of these
 things, to remove the crown, to the end that
 those digital manipulations rendered necessary
 by the populous condition of the Piute head
 may be performed without a too frequent re-
 moval of his beaver.

Orion Clemens

Was a quiet, unambitious sort of man, content
 to discharge the duties of his place with indus-
 try and care, cherishing no political or literary
 aspirations; indeed, his tastes seemed to incline
 him to active work rather than books and study.
 Though a modest and retiring gentleman, he
 possessed a good share of administrative ability,
 as was evinced by his able conduct of the nego-
 tiations carried on between California and Ne-
 vada on the boundary question, of which he had
 charge during a temporary absence of Governor
 Nye from the Territory. After the close of his
 official life, which was ended by the substitu-
 tion of a State for a Territorial government, he
 returned East, leaving many friends and a good
 record behind him.

Samuel, His Brother,

Up to the time of his arrival in Nevada had not
 much distinguished himself in that department
 of literature in which he has since made himself
 so famous. Indeed, there is no evidence that
 he had before ever essayed that line of writing,
 nor is it at all probable that he would have en-
 tered upon it here had he not, having a good
 deal of leisure on his hands, been tempted to
 accept the situation of "local" on the *Territorial
 Enterprise*, the leading paper of the country.
 From the time of his advent into Carson City as
 a member of the "Plug Hat Brigade," this
 brother had been looked upon not only as a
 queer sort of fish but as a genius in his way; a
 careless independence and a habit he had of re-
 marking in his usual drawing manner upon per-
 sons and things with a refreshing looseness and
 in quaint and comical terms, having gained for
 him the reputation of an oddity and wit before
 he had left Carson to enter upon his journalistic
 labors in Virginia City. Here, in his new call-
 ing, with the columns of a paper already noted
 for the utterance of sharp and pithy sayings and
 that audacity of opinion that suits a border
 community, open to his use, Clemens found just
 the channel best suited for giving play to his
 peculiar talent; the *Enterprise* thereafter teem-
 ing with items, homical, sarcastic, or broadly
 humorous; no institution, person or subject
 being too high or too low to escape critical
 notice, though it is but just to say these attacks
 partook more of the burlesque than the censor-
 ous or the satirical.

Mark Twain.

Writing sometimes for the paper on which he
 was employed articles of greater length or on
 some more pretentious subject than usual,
 Clemens signed these with the *nom du plume*,
 then first assumed, of "Mark Twain," this
 style of signature having been adopted, as it is
 said, for the following reason: When acting as
 steamboat pilot on the Mississippi, it had been
 made part of his duty to take the soundings. In
 doing this it becomes necessary to sing out the
 depth of water as indicated by the lead, direct-
 ing the proper scoring to be made, thus: "mark
 one," "mark twain;" the latter, the ancient and
 now nearly obsolete form of the word two.
 From his peculiar manner of drawing this out,
 young Clemens had acquired among the steam-
 boat fraternity the sobriquet of "Mark
 Twain;" which droll phrase being familiar to his
 ear, and pleasing him, perhaps by its originality
 and fitness, was retained for the above purpose.
 This may be a fanciful explanation of the or-

igin of the term in question but we do not recollect of having heard any other suggested.

The First Article from the Pen of the Great Humorist that Attracted Much Attention

Was an account of an inquest purporting to have been held in Humboldt county by a man named Sewell, a protégé of Governor Nye's, and who had by him been appointed Justice of the Peace and ex-officio Coroner for that remote and isolated region. Sewell, though by no means deficient in business tact, was one of those persons who attach undue importance to official position; wherefore he considered his appointment to this empty place as investing him with a degree of dignity and imposing upon him a weight of responsibility the sense of which he could not altogether conceal. He was, moreover, a man of inflexible integrity, prompt and particular, and fond of discharging all of his duties with a punctilious and conscientious exactness that sometimes savored of ostentation.

The Governor had received from this appointee of his several papers, all prolix, and some of them rather extra-judicial, giving an account of his stewardship in this distant and unimportant satrapy; the which had disappointed His Excellency of the good results that he had hoped would come from placing 200 miles of desert between himself and the pertinacious Sewell. In the over-meddlesome disposition and untimely zeal of this Humboldt Justice, Clemens found what seemed a proper subject for one of his characteristic lampoons; in which, after referring to the commendable watchfulness manifested by one so charged with the conservation of the public welfare and peace, the narrator goes on to relate how a party of miners, while out prospecting in the mountains a long way east of Humboldt came upon the well preserved and perfectly petrified body of a man; which circumstance, on their arrival at the county seat, was duly reported to the Coroner. This official impressed with the importance of the fact and the solemnity of the occasion, proceeded at once to impanel a jury and with them repairs to the spot. Upon this body, though evidently a fossil of a very early age, an inquest is held and a proper finding had, after which, according to the account, the remains are, with all becoming formality, granted Christian sepulture. This story is told with a minuteness of detail and a gravity that, despite its evident absurdity, gave it much the semblance of an actual occurrence.

The next characteristic story from the pen of this jocular writer was that recounting the fearful atrocities connected with

The Butchery of the Curry Family;
A tale so inconsistent in its statement of facts that it obtained at home only a partial and momentary credence—the entire narrative being so outrageously improbable that none but the most credulous stranger could be expected to believe it. Abram Curry, better known as Col. Curry, was an old resident of Carson, and a man much given to practical joking; not many of his more familiar acquaintances having escaped being made, one time or another, the subject of some clever trick of his—it being even probable that "Mark Twain" himself might on some occasion have been a sufferer in this way. However that might be, Curry was justly considered a legitimate mark for a shaft from the humorist's quiver. In this blood-curdling narrative Curry is represented as having become suddenly insane, and, while in that condition, to have taken his children, consisting of a large number, and butchered each one of them, also the mother, in a manner simply fiendish. This grimly facetious story was, in fact, so stuffed with horrors that, if the scene had been laid in almost any other country, it would have been regarded as nothing but a canard. Being represented as having transpired in Nevada, however, it met with ready credence in the East and in Europe, where it was gravely commented upon as one of the most atrocious acts recorded in the annals of crime, and as furnishing a fearful example of the general savagism of the community where it occurred.

Among the Earlier Productions of Clemens
Was an article, that at the time created a good deal of amusement and added not a little to his local fame, descriptive of the festivities that attended the marriage of Thomas Hannah, a member of the Territorial Legislature, and in which the peculiarities of several well-known characters about Carson City were happily depicted; a variety of incidents connected with the wedding, itself an event of some note, having also been alluded to in a slightly satirical but altogether laughable manner. His reports to the "Third House" of the Legislature that appeared soon after, though witty and facetious and read with much gusto by those sufficiently well acquainted with home affairs to appreciate the many apt hits and local allusions contained therein, did not wholly gain the popular sympathy, the subject being scarcely a legitimate one for burlesque and some of his remarks being too pointed and personal to be generally well-relished.

He Goes Illy Provisioned on a Prospecting Tour—And Meets With Adventures.

Sam, for it was by this name that he was at first best known among his acquaintances, really did have to wrestle with some pretty tough experiences during the first year of his residence in the Territory; what he relates in this connection in his book entitled "Roughing It," though tinted of course with his habitual exaggeration, being not wholly the fiction of his fertile brain nor yet perhaps very much overcolored. It was, indeed, a short-lived habit he had of making prospecting trips into the mines, a business that necessarily exposed him to some pretty

severe knocks, and in the diligent prosecution of which more bona-fide hard work was called for than this queer genius would be at all likely to perform.

As evidence that he did make such excursions, and sometimes get into a pretty tight place, the following, related by James Stark, the actor, is pertinent. While on a visit to the Esmeralda district, in the fall of 1861, Stark, accompanied by Thomas Hannah, the gentleman above alluded to, fell in with Clemens, then out on one of his so-called prospecting tours. At the time these parties encountered him a little way out of the town, he was sitting upon his hat in a sunny spot smoking a merchaum pipe, which, with a jack knife and a tobacco pouch constituted his entire mining outfit. He was without pick, shovel or culinary utensils, which latter, indeed, would have been a superfluity, seeing he had nothing with him to cook.

His Wardrobe and Toilet.

According to Stark's account, "Twain" must, at the moment the actor and his companion fell in with him, have presented an appearance outlandish and *outré* to the last degree. His feet were encased in a pair of cowhide boots reaching to the knees, and which, being many sizes too big for him, had so turned over as to bring the soles into a nearly vertical position. Into the tops of these stogies were tucked the legs of his blue overalls, which rent and sacky about the seat, were supported above by a single greasy suspender. A gray shirt, stiff with dirt and well ventilated at the elbows, did duty for both coat and vest. His hat, a tall and conical felt, turned down behind and up before, stood on his head like the section of a huge bologna sausage, pointing toward heaven, as if it would thitherward lead the way, had the owner shown any

An Important Improvement in Telegraphy.

The district telegraph system is one of the outgrowths of the advance of science and civilization, and fast becoming as much of a necessity in large cities as the fire alarm or anything else for the convenience and protection of citizens and their property. When the system was first started the mechanical means of carrying out the idea, on which everything of course depended, were very crude; and although considered sufficient at the time, the needs of the district telegraph gradually increased, and new and more improved mechanism became necessary. When people found they could summon a messenger, the policeman, or the fire department at will, they soon became desirous of having other "calls," and naturally thought these could be added to the machine without the necessity of summoning a messenger to convey their idea. It needed, however, a skilled and ingenious electrician to take hold of the district telegraph box and so improve it that it would answer the demands. This electrician had also to be an inventor, and one of no mean capacity, moreover, in order to properly improve the crude signal box first used.

It remained for California to find the man to invent and carry out the improvements required, in the person of Stephen D. Field, an accomplished electrician and inventor residing in this city. Mr. Field is a nephew of Cyrus W. Field, the projector and constructor of the original Atlantic cable. For a number of years Stephen D. Field was electrician of the Western Union Telegraph Co., and now holds the posi-

very important one and is operated as follows:

It consists in the combination with each signal box of an alarm, or sounding apparatus, consisting of a series of tripping levers, a trigger and an alarm device, which are so arranged that the alarm can either be set by the act of transmitting a signal, or by an independent action, and afterwards be released by the operator at the central station by shunting a portion of the resistance in the line circuits, increasing the battery power, or reversing the line battery, so as to sound an alarm or signal at the particular box from which a signal has been received. The alarm is connected with the same wire over which is transmitted the signal from the signal box to the central station, but the inventor interposes in the same circuit an electro-magnet of low resistance that will not be affected by the electric current in ordinary use upon the line, so that signals can be transmitted over the line after the alarm is set without affecting the electro-magnet or alarm mechanism. After the signal has been received at the central station the operator or receiver can, by simply increasing the battery power, or by shunting a portion of the resistance in the line circuits, or by reversing the line battery, sound the bell at the box from which the signal was sent so as to notify the sender that his signal was received and understood.

In this "electro-mechanical" apparatus the inventor prefers to use the "heel and toe" system of levers on the tripping device because this allows a greater throw of trips with a smaller magnetic force. The theory being that as magnetism diminishes in proportion to the square of distance from armature the shifting of the leverage allows a very feeble attraction to start the action. Electro-magnets have heretofore been used in signal boxes in the following manner: First, by cut-off opened when the box is started and cut out by the train when the signal is complete. This gives a rattling sound, by the vibration of the magnet armature while the signal is being sent, but as the box gearing accomplishes the cutting out it is impossible for the operator at the central station to respond that he understands. Second, a magnet, with its armature or other sounding devices permanently in circuit and responding to all breaks and closes on said circuit. This device is objectionable because the great number of magnet coils, one in each box, requires an immense battery power, and also because of the annoyance caused box-holders by the tapping of signals other than their own. In Mr. Field's device the cut-off is removed by the action of starting the box and replaced by the action of the operator at the central station in responding his understanding of the call. The improvement, therefore, embodies a cut-off opened by the subscribers, either unconsciously, while setting the box, or at pleasure by moving a special lever (which may be an extension through the side of the box of the arm) and closed by an increase of the battery power however obtained; the end to be obtained being to return a responsive signal from the central station to the person sending in a signal, that the signal has been received and understood. This arrangement of signals and response can also be used in hotels and similar places instead of the annunciators ordinarily used.

Another improvement devised by Mr. Field is a means of correcting any mistake of the sender of the message, in case the pointer is turned to the wrong "call." Even with the improved box, before the latest additions were made, in case the sender of the message turned the pointer past the call he intended to make—something which frequently happened—he had no alternative but to send the wrong message or none at all; and this because there was no means provided for moving the pointer back without pulling down the lever and sending the message. By a simple contrivance operated by a button, *C*, over the box, it is now so arranged that in case the pointer is set at the wrong call, the sender, before sending the message, can press on the button and bring the pointer back to the place and then re-set it properly before pulling down the lever which sends the message.

These boxes are now made in this city in the style shown on this page, by the Electrical Construction and Maintenance Company. Large numbers are now being made for shipment to New York, where they are replacing the old-fashioned signal boxes, and it will not be long before they are introduced into every large city where they have a district telegraph system. They are now in use in this city and Oakland, and also in San Jose.

TELEPHONES IN MINES.—The *Mining Journal* calls the attention of mine owners to this wonderful instrument, which was lately described in this paper. A telegraph wire can be laid through the mine, and with telephones at a few important stations, conversations can be carried on between those in different parts of the mine and those on the surface. Should an accident occur, the prompt notification of it and its nature might save many lives and much property; and the possibility of conversing freely between distant points without the necessity of skilled operators will unquestionably prove an incalculable advantage in mining, as it will be in other departments of industry.

On the first inst., the timbers in the Oak Grove gravel mine, on McAdams creek, near Yreka, gave way, letting down about half an acre of the mine. Luckily the workmen had just come out of the mine for dinner. Otherwise all would have been caught beyond any possibility of being saved.

IMPROVED DISTRICT TELEGRAPH SIGNAL BOX.

disposition to follow. This hat, when the miners first beheld it they marveled greatly thereat; saying the one to the other, of a truth, this is the plicene fossil of which we have heard others speak. In short, if the story of the great actor may be credited, "Twain" was just then a spectacle pitiful to contemplate and ludicrous to behold.

He Introduces Himself.

Neither of these gentlemen had any acquaintance with "Mark," but he, recollecting to have seen Hannah before, came up and introduced himself in his usual slothful style of speech, somewhat as follows: "M' name's Clem-ens. Reckon y' know me brother Orion. Dam'n, sent me out 'n sage-brush here 'thout a red. Grub's gone—m' nearly starved. Call it tight pa-pers—dam'd 'f don't. Cabaged couple cans oys-ters las' night. Eat'm all t' one meal. Cook'd cans fr soup 'smornin'—s' nearly hell."

Seeing the fix he was in and that he was a comical genius within, Hannah invited him to go with them and get something to eat. This invitation having been accepted, the three made their way into the town, and repairing to a restaurant, the best dinner to be had was ordered. As the viands were served up, Clemens, who was at all times a good feeder, proceeded without ceremony to largely sample every dish as it came to the table. The others found time for social converse, but not so their guest, who, complimenting the *cuisine* of the establishment by hastily devouring one dish after another, looked his gratitude to his entertainers, time being too precious for speech. Seeing the strait he was in, Hannah gave "Mark" money enough to take him back to Carson, for which place he set out on foot the next morning.

Among other Esmeralda adventures that Clemens liked afterwards to talk about, was the manner in which he managed to elude an overhauling at the hands of a mining company, whose claims he had indiscreetly attempted to jump. In the adjustment of this matter, his droll manner and jocular talent seem to have served him an excellent purpose, the outraged miners amused with his ready wit and awed at his original modes of lying, having incontinently let up on him.

tion of electrical engineer to the Electrical Construction and Maintenance Co.

The old district telegraph box when first taken hold of by Mr. Field was a small one, very rough in appearance, and with a capacity of sending only three messages to the central office. Having an intimate knowledge of all telegraphic apparatus and a strong liking for his profession aside from pecuniary advantages, it was not long before a much more perfect apparatus was devised by the young inventor, and he has been continually improving it until the apparatus is now one of the most complete pieces of electrical mechanism known; and probably the most ingenious invention ever patented in California.

The apparatus consists of a dial with indicating pointer, *B*, the dial carrying on its face various names showing the various services rendered by the company. Inside of the box is a series of wheels and levers in immediate connection with the dial and also in electrical connection with the signal lever, *D*, the whole being enclosed in a neat cylindrical brass case, handsomely nickel plated. The knob, *A*, serves to turn the pointer, *B*, to the proper position.

The operation of the box is extremely simple, although the mechanism is ingeniously devised and apparently complex. By turning the indicating pointer to any desired "call" upon the dial, the apparatus within the box is put into position to send that particular call and none other—a proceeding analogous to setting type, only in this case the setting and distributing are both mechanically performed. When the pointer is found to be resting on the proper call, a depression of a lever on the back of the box starts the gearing in operation. This automatically transmits the signal to the central station and at the completion adjusts the pointer back to its initial point, or the "messenger" call. Mr. Field's most recent improvements, for which he obtained letters patent through the MINING AND SCIENTIFIC PRESS Patent Agency last week, consist in providing the apparatus with an answering back signal, for the purpose of returning a signal from the central office to the subscriber, indicating the receipt and understanding of the call. This improvement is a

The Summer Mine.

A correspondent of the *Courier-Californian* says: "As you requested sometime since, I write to let you know something of what is going on here, and of our business prospects. Our prosperity depends almost entirely upon the success of the Summer mine, and the development of the Summer mine has been dependent upon Senator Jones's capital; so you will readily see that we are dependent upon the faith which the Senator may have in the mine. The mine is a very large true fissure vein, of miles in length, carrying some gold the whole distance, and where the principal works are there have been several bonanzas of excellent ore near the surface, and over a million dollars have been extracted and added to our circulating medium, and the prospects were considered favorable enough to go down on the mine. In sinking, a much larger body of water was encountered than was anticipated, and works have been added from time to time, until there are now as complete and extensive works for sinking and hoisting on the mine as on this coast—sufficient to sink on the mine at least 1,500 feet—and involving an outlay on the Senator's part of \$800,000. He has responded nobly thus far, but any one might weary in 'putting up' after a while, and the largest purse run low, and we people who are dependent on the mine for bread and butter watch the developments, perhaps, with more anxiety than those who have expended so much on it; and it is with great pleasure that I can assume you that prospects in the mine look much better than at any time since sinking was commenced. I visited the mine on the 14th, and on the 300-foot level they have a breast of ore of over 20 feet in width, for over 80 feet in length, and are still running on it. The east wall has not been reached yet, but from indications the ore-shoot must be at least 25 feet in width. The 80-stamp mill has been running for the past week, but I understand that it will have to hang up again for a day or two, for a reason unheard of before in this locality, viz: for want of hands to extract the ore. Of course, after the stopes, etc., are ready, very few hands comparatively will be required, but it takes a large amount of ore to keep 80 stamps at work. "As it now looks, I think our bread and butter is assured, and that soon Senator Jones will be receiving from the Summer mine instead of disbursing, and I hope as liberally."

New Laws for Homestead Entries.

The following is a copy of a law passed at the last session of Congress. It relieves parties of the trouble and expense of visiting the land office in the district in which they may reside for the purpose of making proof of residence, etc.:

An Act to amend Section 2,291 of the Revised Statutes of the United States, in relation to proof required in Homestead Entries.

Be it enacted by the Senate and House of Representatives of United States of America in Congress assembled, That the proof of residence, occupation or cultivation, the affidavit of non-alienation, and the oath of allegiance required to be made by Section 2,291 of the Revised Statutes, may be made before the Judge, or in his absence, before the Clerk of any court of record of the county in said State or district and Territory, in which the lands are situated, and if said lands are situated in any unorganized county, such proof may be made in a similar manner in any adjacent county in said State and Territory; and the proof, affidavit and oath, when made and duly subscribed shall have the same force and effect as if made before the Register or Receiver of the proper land district; and the same shall be transmitted by such Judge, or the Clerk of his court, to the Register and Receiver with the fee and charges allowed by law to him; and the Register and Receiver shall be entitled to the same fees for examining and approving said testimony as are now allowed by law for taking the same.

Sec. 3. That if any witness making such proof, or the said applicant making such affidavit or oath, swears falsely as to any material matter contained in said proof or oaths, the said false swearing being willful and corrupt, he shall be deemed guilty of perjury, and shall be liable to the same pains and penalties as if he had sworn falsely before the Register.

Approved, March 3d, 1877.
An Act for the Relief of Settlers on the Public Lands under the Pre-emption Laws.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, that when any person who has made a settlement on the public lands under the pre-emption laws shall change his filing to that for a homestead entry, the time required to perfect his title under the homestead laws shall be computed from the date of his original settlement made under the pre-emption laws.

Approved, March 3d, 1877.

Refrigerator Shipments.

There bids fair to be no lack of designs in car building to accomplish the prolonged carriage of meat and fruits. There promises to be as many of them as there are of fruit driers or spotted steers. We are not prone to have them less. We would give to each as warm a welcome as its cold nature will admit of. Competition will make them move like warmed molasses and if they get up a contest for the possession of our fruits, meats and vegetables,

which will increase the farmers' rewards for these lines of products, we bid them railroad speed. We have an item in another column of the organization of a new refrigerator car company in this city, and we now read in a Chicago paper of the successful movement of perishable produce from Colorado to Chicago in one of another design. We shall quote some statements of results with this car, because they contain experiments with moving fresh meat nearly as great distances as are now contemplated in the shipments from this State and Nevada. A Chicago journal, of a recent date, says: "A few days ago quite a sensation was created at the Chicago and Alton depot by the arrival of a Tiffany 'summer and winter' refrigerator car from Pueblo, Colorado, with beef consigned to Thomas Armour & Co., of Chicago. Though eight days on the road, with the thermometer through the week ranging at 90° in Kansas, and receiving no more attention than ordinary freight, the beef was found to be, on examination, in perfect condition, and fit for immediate use. Last January a car-load of dressed beef was shipped from West Las Animas, Colorado, consigned to A. F. Anderson & Co., of Chicago, and though it remained on the car 14 days, and was subjected to a fluctuation of temperature varying from nine to 30° below zero, when unloaded was found to be perfectly fresh and sweet, and was rapidly disposed of in advance, while beef shipped at the same point, in an ordinary car, and arriving at Chicago at the same time, was so frozen that a crowbar was necessary to separate the quarters, resulting in such damage as to render it unsalable. Fruit and vegetables have been transported with equal success, strawberries having been kept eight weeks on the same principle. In a few days a car will be sent to San Francisco, to bring back a car-load of fruit."

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quicksilver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, \$2.50 coin, or \$3 currency, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE, \$7.50.

We carry the N. Y. watch, and you can refer to the publishers of this paper as to the superiority of the N. Y. Watch Company's movements, manufactured at Springfield, Mass. Also to any one else who owns one.

EVERY new subscriber who does not receive the paper and every old subscriber not credited on the label within two weeks after paying for this paper, should write personally to the publishers without delay, to secure proper credit. This is necessary to protect us against the acts and mistakes of others.

ORDERS for the GOLDEN PIANO will be received at this office, where further information can be had concerning their excellent qualities and favorable prices.

WHEN so many poor watches are being sold, it is not too much for us to say that those who buy the New York Watch Company's movements will be sure of a good article at fair prices.

PASO ROBLES, CAL., October 18th, 1875.
DEWEY & CO.—Gents:—The letters patent for the Fire Upsetter have come to hand. For the prompt manner with which you have brought the matter to a successful issue, please accept my thanks. Yours respectfully,
JOHN H. MERTZ.

Steam Engines & Boilers, NEW AND SECOND-HAND.

One Patent Straw-Burning, Portable Engine, (new,) fire box boiler, the best Portable Engine on the coast; built by Ransom, Sims & Head, Ipswich, England.

One Steam Fire Engine, second-hand, in excellent condition, with 200 feet leather hose, very cheap, just the thing for a small town. Button & Blake, builders, Waterford, N. Y.

One second-hand Stationary Engine, 14x30 inches, link motion, with or without hoist gear.

One second-hand Stationary Engine, 8x20 inch, with or without hoist gear.

One Upright Boiler, Horizontal Engine on wheels, Eastern make, 7x12.

One Upright Boiler, Horizontal Engine, San Francisco make, 6x12.

One small Stationary Engine, 3½x7 inch.

One Steam Boiler, 40 inches diameter, 16 feet long.

One 8x10 Straw-Burning Portable Engine.

One Stationary Engine, 8x16, and Boiler, with pump heater, fire front and smoke-stack, complete.

One Traction Engine, three wheels, rubber tires, double cylinder, 6x10 inch; Thompson's patent, D. D. Williamson, builder, New Jersey.

Various other second-hand Engines and Boilers for sale cheap.

J. W. RILEY,

P. O. Box 2361.

San Francisco.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

A. J. SEVERANCE & CO.

Office, No. 320 Sansome street, Room 10.

San Francisco Pioneer Screen Works,

J. W. QUICK, MANUFACTURER,

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

HYATT'S LIFE BALSAM.

As a conqueror of Rheumatism, Gout, Neuralgia, and cure for Scrofula and all diseases arising from impurity of blood, the old and reliable Family Medicine, Hyatt's Life Balsam, stands unequalled, as proven by over 300,000 great cures during the past 30 years. Is a radical vegetable compound of Sarsaparilla, Dock, Guaiacum, etc., and a permanent cure. Sold by all druggists and country grocers. Take nothing else, and if they haven't it we will send by express, boxed, everywhere, at \$1 and \$1.25 per bottle; \$5 and \$6.50 half doz. HYATT & HYATT, 246 Grand street, New York.

MOUSTACHE PROTECTOR.

Gents' Delight. Boss Novelty for Agents. Big to sell. Gents must have it. Ladies buy it for them. Only 25c by mail. Circulars free as air. Storekeepers, let me whisper to you. C. H. BARROWS, Patent tee, Willimantic, Conn.

PACIFIC RURAL PRESS.

A first-class 16-page Illustrated Agricultural Weekly, filled with fresh, valuable and interesting reading. Every farmer and ruralist should take it. It is immensely popular. Send for a sample copy.

DEWEY & CO., Publishers, S. F.

FOR SALE OR LEASE.

Corey & Kingery Mine for Sale or Lease. This mine is a gold bearing quartz lead, situated on French Creek, Siskiyou county, Cal., 7 miles south of Etna. Mine opened by tunnel and shaft 170 feet below surface; average width of lode, 18 inches. For further particulars call and examine our mine, or address us at Etna, Siskiyou county, California.
H. O. COREY,
D. B. KINGERY.

Our readers can see watches second to none of American make, by asking "the time o' day" when our agents call. They travel by the N. Y. watch, and are very proud of them.

We can recommend the New York watch, of Springfield, Mass., as A 1.

Continued from page 277.

Upon the Richmond and American mines, shafts are being sunk. At 12 feet, the Richmond shows a vein four and a half feet wide. The ore is antimonial sulphate, and the assays range all the way from \$200 to over \$300 to the ton. Mulvenon & Roach will start up their furnace in a few days, on ore from the United States mine, in Copper canyon.

In Bradshaw district the new Luke & Co. road is nearly completed. Eight teams are on the road, loaded with mill machinery. Work is being carried on upon the Gretna, and a good character of ore is being taken out.

In Peck district, the tunnel upon the Whipple mine is now in 20 feet. This ledge crops out boldly and carries a strong vein of silver-bearing ore. A shaft is being sunk upon the Mountain View, and shows a good ledge and an excellent prospect. Upon the Silver Prince, Messrs. Houghton & Curtin are running levels from the main shaft and are getting out some very high-grade ore. The work is still progressing on the north tunnel of the Peck. Messrs. Hague, Walsh & Fogus have been out examining the mine. They brought in some 20 different samples of ore, which they have had assayed by Messrs. Kelly & Drew, the assayers, with favorable results. The mine shows an immense value in all of its veins, some estimating it as high as \$1,000,000. It has been excellently worked and is in good condition, demonstrating the fact that it is a good thing to have good mining men to work upon any mine. Rich ore is being received in Prescott daily by all the assayers from prospectors, and prospecting is being more vigorously carried on in this country than ever before. The Agua Fria furnace is running on Black Warrior ore, and is working about three tons per day.

From Mohave county we learn that the Silver Glance mining company have just completed a 13 days run. They worked an average of 12 tons per day, and have as a result 104 tons of high grade bullion.

The McCrackin company's mill was closed down for a few days, waiting for chemicals, but the mill has started up again and is running excellently. The dumps on the mine are full to overflowing of ore, and an enormous quantity has been taken out in the past few months, yet there is an immense quantity in sight in the mine.

A good many men are at work in Cedar Valley district, and great many arastras will soon be running.

In our county the miners are not by any means idle. The Bradshaw mountains and the Sierra Prietas are full of prospectors, hunting for their share in the brilliant outcome which will soon be the legitimate result of the interest now being shown by prominent operators in our mines.

In the Bradshaw mountains, Riggs and Hammond, upon their claim on the Tiger, now have their tunnel in 150 feet. From the tunnel they are running a cross-cut to tap the upper vein, and have it now 60 feet into the mountain from the face of the tunnel.

Upon the original location of the Tiger a survey has recently been made for a tunnel. This tunnel is intended to drain the main shaft, in which water accumulates rapidly. This shaft is down 90 feet, and this tunnel, when run, will strike the ledge 44 feet below the tunnel.

A large number of men are at work in Bradshaw district, and the camp is resuming the activity of former days.

This Luke's mill machinery has arrived at Walnut Grove and is being carried by Palmer's ox-teams to the mill-site. The putting up of the mill has been put under the efficient supervision of Mr. Charles Pietz.

Several men have recently gone to Castle creek to mine in the gulches.

A rich lead has been struck on Wolf creek, in Turkey Creek district. The surface indications on this vein are said to be wonderful. The ledge is about two feet to 30 inches wide, and is very high grade chloride ore. One assay, from surface rock, from this new discovery, gave over \$6,000 in silver. It is called the Mexican.

Colorado.

TERRELL.—Colorado *Miner* April 21: The pump has now been at work about two weeks, and is getting the water out of the mine rapidly.

The Union tunnel is steadily progressing toward the Terrell, which lode it is intended to develop. The silver ore tunnel is being pushed on to the Brown. It is already about 300 to 350 feet beyond the Terrell.

SILVER PLUME.—We hear that another strike of rich ore has been made on this mine, but how large a pocket has been found is not yet known.

PAY ROCK.—Is working from 20 to 30 mon. The mine is now in about as good pay as at any time.

P. McCANN & Co. have started up the Cree mill and are now in the market for silver and lead ores.

ATLANTIC.—This lode is now being worked under lease. There are about 15 men employed upon it. The ore vein is from one and a half to two and a half inches of rich ore, the first-class yielding about 1,300 ounces per ton.

SNOWDRIFT.—We are glad to hear of a rich find in this mine, which has not been heard from so long. The last run gave between 600 and 700 ounces for the first-class ore.

SILVER GLANCE.—George Hammond & Co., lessees of this lode on Democrat have struck the second "pocket" with the "Glance tunnel" and have from one foot to 18 inches of mineral which mills from 200 to 600 ounces of silver per ton.

The Central S. M. Co. have been developing their property in Peru district, Summit county, during the past winter. A cross tunnel now 30 feet long—is being driven into Ruby mountain, which will cut a number of lodes owned by the company, at an acute angle, and as the veins cut the mountain quartering, the drifts on each will gain depth as they advance. One lode has already been crossed. Although little more than prospect holes have been sunk so far, some of the veins show good mineral, specimens of which tested here contained as high as 430 ounces.

Idaho.

NEW DISCOVERIES.—Idaho *Statesman*, April 24: Years ago rich specimens of float quartz were found on the head waters of Willow creek, some 20 miles northwest of here. This fact was best known on the Payette by parties who saw the specimens. The diggings on Willow creek have been worked out for several years, but not with much success. For several years prospectors have hunted over this range of hills to find this supposed lode. We learn by Mr. Hawley, of the Payette, that Mr. D. Passmore has struck and is now operating a rich lode of gold bearing rock on the head waters of Willow creek, believed to be the lode so much hunted for by prospectors. Mr. Henry Padon and his son-in-law have found and located places diggings just below Passmore's lode that will pay two cents to the pan and it is counted good hydraulic ground. Water is scarce for placer mining; nevertheless, they think they can corral the heads of several creeks and get water for two or three months in the year. Both parties are highly elated with their discoveries and others are visiting their camp and prospecting in that section for more gold. This discovery will no doubt lead to considerable mining on Willow creek.

GOLDEN CHARLOT.—Idaho *Avant*, April 23: The mine continues to look well and the work as it progresses in the different sections of the mine presents the most cheering developments. The 1300-ft level is now in nearly 300 feet, and the vein at this point, although not as large as usual, contains a heavier streak of mineral, the gold predominating. The operations in driving south from the cross-cut to the Crane and Briggs are being attended with the most favorable results. There is abundance of good ore in the face of the drift. The stopes south from the winze between the 6th and 7th levels are yielding large quantities of high grade ore, and everything in and about the mine presents a most promising complexion. The most satisfactory results are attending the economical and energetic management of Superintendent Baldwin. Private letters received here from Captain Bledsoe, at San Francisco, state that he has been successful in negotiating with some capitalists there who propose to commence operations without delay at Atlanta. That camp presents an inviting field for the investment of capital.

JOHN CATALDO, Esq., is expected here from below in a day or two. It is rumored that he has a "pocket full of rocks," and will probably make arrangements to start up the Oro Fino in a few weeks.

GREAT hopes are entertained in connection with the prospects of carrying forward operations in the Poorman on a large scale the coming summer.

This Belle Peck is looking well. Some inconvenience is still being experienced in battling with the water. There is no doubt of the existence of a promising ore body at the point of present operations.

The Potosi crushing of 112 tons yielded \$26 to the ton. There was quite a loss somewhere, as the tailings assayed over \$24.

Montana.

PLACERS.—Helena *Independent*, April 16: Hortop & Wright are running a hydraulic. Their ground pays well. There is considerable activity manifested just now by the miners on the foothills around Cave gulch. The water is abundant and all the claim owners have begun work. Several companies will work on Grewell's bar this season, and the prospects are very flattering that it will pay well. The gold obtained is of fine quality and the quantity is very satisfactory to those owning the mine. Magpie miners are washing out considerable money from the drift diggings, and Loomis, Harris & Co. are running a hydraulic—have been all winter—and are making good wages. Some of the small gulches adjacent to Magpie are being worked, and all pay fair wages, but none of them are remarkably extensive or rich. The miners in St. Louis gulch and its tributaries, and others adjoining, are now working with the greatest vigor. There is said to be an abundance of water, and the mines have always paid well heretofore. It is safe to predict that the mines in that section will yield much more gold this year than they did last, as the working season promises to be at least one month longer than usual.

SHUT DOWN.—The recent order from the President's office of the Hope mining company, in St. Louis, to "close down the mill, annul all contracts and close the mine," was received here on Saturday, and created much surprise. The apparent reason for this action, the Superintendent asserts, may be found in the present suit, instituted by the County Commissioners to collect taxes upon the entire products of the mill during the year 1876. During this time, we have reason to believe, 3,000 tons of ore was mined and milled, averaging about \$50 per ton in the mill, the tax upon which is an item of interest to the company, and a question of law involved, which the company propose to have settled before proceeding further so we are informed. The surprise arose from the fact that it was well understood the mill had plenty of pay ore in sight, the machinery in good running order and a full supply of chemicals on hand.

All is still silent upon the premises of the Northwest company. The machinery is rusting for want of use, and plenty of first-class ore waiting to be reduced.

When at Oli's concentrating works, last week, we found B. Parks employed in sacking and getting ready for shipment to Baltimore, a lot of about 38 or 40 tons of copper ore, which had just been finished up.

From parties just arrived from Salt Lake and Franklin, we learn that there are large numbers of men on the road making their way north, some on foot and others on horseback, seeking employment in the mines of the Territory. Some are heading for Pony, some for Pioneer and others for Butte and Phillipsburg.

From a party just returned from Pony, we learn that the camp is lively and full of people, but there is very little money circulating as yet. Indications are promising, however, for a speedy change in this respect.

Mr. Roast returned some days ago from Radersburg, where he had been to secure an engine and boiler to drive the machinery for the saw mill, now being erected by Roach & Co., on Dive creek.

Prof. Smith informs us he will hereafter run his works day and night, commencing to-day. The arastras have been idle for some days past, owing to having no ore on hand, the roads up till recently being in such condition as to make it almost impossible to haul any amount from the mine. A supply of ore has now been delivered, however, and the works will be kept steadily running.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco.

BRANZAN KING M. Co.—April 23th. Location: Arizona. Capital stock, \$10,000,000. Directors—C. L. Place, E. Johnson, T. C. Johns, S. S. Tilton and A. W. Scott.

CALIFORNIA DREDGING CO.—April 23th. Object: To manufacture and sell dredging machines. Capital stock, \$1,000,000. Directors—Charles H. Swain, B. Hedge, H. B. Butterfield, W. E. S. Whisman and C. E. Buckingham.

GOODYIN M. Co.—April 23th. Location: Arizona. Capital stock, \$10,000,000. Directors—Robert Sherwood, C. W. Fox, William M. Lent, Edmund G. Peck and M. Masterson.

MASSASOIT M. Co.—April 23th. Location: Arizona. Capital stock, \$5,000,000. Directors—F. C. Remington, J. W. Brown, C. F. Balcorn, J. A. Chandler and Joseph Baloun.

PROCESSE G. M. Co.—April 30th. Location: California. Capital stock, \$6,000,000. Directors—E. Brewster, Abraham Halsey, Edmund Green, G. Palache and J. E. Kelly.

ENDOWMENT M. Co.—May 1st. Location: Nevada. Capital stock, \$10,000,000. Directors—R. Webber, W. B. Crane, Thomas Cole, G. W. Grayson and C. W. Crane.

ALBION RIVER RAILROAD CO.—May 1st. Capital stock, \$40,000. Object: To operate a railroad commencing in the southeast quarter of section 23 and running into and through section 27 in northeastern direction, or as near thereto as the route shall be found most practicable, to connect with Albion river, in township 16 north, range 16 west, Mount Diablo meridian, in Mendocino county, State of California, under and pursuant to the laws of the State of California. Directors—Henry Wetherbee, Thomas Pollard, A. W. McPherson, Jr., George A. Gray and John Dolber.

SILVER KING M. Co.—May 3d. Location: Pioneer district, Arizona. Capital stock, \$10,000,000. Directors—Jas. M. Barney, Benjamin W. Regan, George L. Wood, Benjamin A. Barney and Wm. H. Booth.

Introduction of a New Blasting Powder.

The Judson powder manufactured by the Giant Powder Company in this city, is a new style of explosive intended as a substitute for black powder, to which it is superior. It is sold loose, or made into cartridges if desired. We have been shown several testimonials from large companies who are introducing this powder in gravel mining, of which the following is a sample:

OFFICE MILTON MINING AND WATER CO.,
San Francisco, May 2d, 1877.

Messrs. Bandmann, Nielson & Co.—DEAR SIRS: Mr. Y. G. Bell, Superintendent of the Milton mining and water company, writes me under date April 29th, 1877, that the two blasts fired in our claim with "Judson powder" were a complete success, as far as he can judge from appearances.

Speaking of one of the blasts where he used the equivalent of 70 kegs black powder, he writes "that it broke much more ground than we anticipated, and it looks as if the gravel was much better pulverized than black powder would do." From a very indication it broke up at least 50% more ground than the same amount of black powder would have done. The foreman thinks it did as much execution as 150 kegs of black powder."

Do not fail to ship us our 10,000 pounds Judson powder by next Friday's steamer, via Marysville.

Very truly,
H. PICKING, Sec'y.

Treating Base Metal Ores.

EDITORS PRESS:—The description of "Stewart's new process" in your last issue, seems to call for a few remarks as being open to criticism from several points of view.

Passing over the possibly questionable statement that metal sulphates are to be found in ore which has been subjected to a chloridizing roasting, we find in the next sentence the assertion that "oxides of iron, copper, zinc, etc., * * in presence of metallic iron and the undecomposed salt and sulphate of soda * * form soluble iron, copper, zinc, lead, etc., which, in presence of metallic iron, are precipitated." * *

Now, again passing over the obvious error of saying that iron is precipitated from such a solution under such conditions, I would observe that oxide of iron is not soluble under the given circumstances; oxide of zinc is doubtful, and an entirely erroneous view is taken and conveyed of the solubility of copper and lead oxides, which is due, not directly to the presence of metallic iron, salt and sulphate of soda, which alone would not produce any such result, but to the fact that metal chlorides are also present; which, if reducible by metallic iron, as chloride of silver, lead, copper or zinc, produce chloride of iron, which then acts on any oxides of copper or lead in the ore, dissolving them as chlorides, to be again decomposed by metallic iron, and reduced to metal which enters the amalgam.

The reason that a simple hot water leaching is not effectual in preventing the formation of base metal amalgam is two-fold. Firstly, hot water will fail to extract dichloride of copper and sulphate of lead, which are directly reducible by the iron pan, producing metallic copper and lead; and secondly, the oxides of copper and lead also remain, and are reduced indirectly through the solvent action of chloride of iron, produced in the first place by the reduction of above mentioned dichloride of copper and chloride of silver, also, in presence of salt, of sulphate of lead. Thus it is seen that protochloride of iron which, in the article referred to, is incorrectly credited with all the results of the Stewart process, always and necessarily exists in the pulp when roasted silver ore is worked in an iron pan, or a barrel containing scrap iron.

Why then does or should the Stewart process give a better result than the ordinary method, since protochloride of iron is present in both? Partly because the base metals contaminate the quicksilver in the latter, and partly because it is not chiefly nor directly the protochloride of iron which does the work in the former.

The action of the bath of protochloride of iron and common salt, the effects of which I described as to its action on oxide of copper in your columns in March, 1865, and as to other effects at various times, and for which, it having been once known as Hunt's, then as that of Hunt & Douglas, and in the article under discussion being designated by the somewhat comprehensive title of the Hunt, Douglas and Stewart, I beg to suggest, the (honorary but harmonious) prefix of my own patronymic, thus: the Aaron, Hunt, Douglas and Stewart bath; the action I say of this much-named bath is somewhat incorrectly stated in the article from the Colorado *Miner*.

Alone, the protochloride of iron and salt solution will dissolve oxide of copper, forming chloride and dichloride of that metal, and oxide of lead as chloride, which, however, in presence of sulphate of soda in roasted ore is converted into sulphate of lead. It cannot dissolve oxide of iron nor dichloride of copper. By the action of the air, however, on the bath a quantity of perchloride of iron is produced which dissolves dichloride of copper, etc., and acts on various sulphides, if present, producing very complex results, among which is free acid. (V. "Keris' Metallurgy.") It also attacks quicksilver, forming calomel, which must be guarded against.

The presence of sulphurous acid prevents the formation of perchloride of iron, and dissolves oxides of iron, copper and zinc, also zincblende and probably other sulphides. Dichloride of copper is not injurious to quicksilver, as incorrectly stated; but oxychloride (which is decomposed by sulphurous acid) converts it into an oxide, and is therefore injurious.

Protochloride of copper, which is formed by the action of protochloride of iron on oxide of copper, and by that of perchloride of iron on dichloride of copper, converts quicksilver into calomel.

Now, in an iron pan neither perchloride of iron, nor either of the chlorides of copper can exist for any length of time, owing to the reducing action of the metallic iron, which speedily converts them all into protochloride of iron, and as the former and not the latter are useful in acting on the unroasted portion of the ore, it is easy to see that pans are to this extent disadvantageous for roasted base ores, and still more so for unroasted ores when chemicals are required for its reduction.

The Stewart process as described, is a jumble of doubtful utility of several processes, among which are that described as "Aaron's process" in my little work on "Testing and Working Silver Ores," the Hunt & Douglas process, and

a process patented some years ago, in which the ore is treated with a bath of perchloride of iron and hydrochloric acid, with recovery of the bath.

I think the process of doubtful utility because of the great danger of injury to the quicksilver, and consequent great loss of that metal. The only apparent advantage it offers over Aaron's process, above mentioned, is in recovering the bath, which recovery being combined with amalgamation, seems also to be the only patentable novelty, but being patented, and involving a good deal of extra trouble, as well as additional outlay, is of questionable benefit.

Aaron's process is not patented, except that modification in which sulphurous acid is used as an aid in amalgamation, which is patented, to which I beg to call the attention of parties concerned.

Where it is desirable to save the copper contained in an ore, it would seem that the Hunt & Douglas process, pure and simple, fulfills all the requirements, for as shown by another recent paragraph from the Colorado *Miner*, Mr. Stewart has found that it can be so modified by means of perchloride of iron (not protochloride as stated) as to extract the gold as well as the silver perfectly.

C. H. AARON.

Mechanical Ore Concentration and Separation—No 24.

[Written for the PRESS by FRANCIS M. F. CAZIN, M. E., Santa Fe, New Mexico.]

What is on the Basis of all Practice in Mechanical, Mineral—Concentration and Separation.

When in the introductory remarks to this treatise, "specific gravity" was mentioned, it was done so for the practical purpose of showing the extent to which mineral dressing is applicable and where the natural limits of its application are. The relative density of materials constituting metallic ores or other useful minerals was then enumerated, and the way was indicated to ascertain the degree of such density. It now remains to explain why specific gravity (density) is the principal quality to be acted upon for the mechanical separation of minerals according to quality.

In examining the table of densities previously published, it will be observed that most valuable minerals being the ore of metals, exceed in density such of all rock accompanying them as matrix, whether in fissure veins or in stratified or in irregular deposits.

Experience now has shown that particles of equal size, but of unequal density, when allowed to drop from the surface of a liquid of still less density, will arrive, the one of higher density sooner at the bottom than the one of lower density. On this elementary experience all mechanical mineral dressing is based, and on some modifications of this experiment, which will be detailed hereafter.

'What is Equal Falling?'

As "equal falling" is designated solid particles, which, when simultaneously dropped from the surface of water of more or less density, will simultaneously reach the bottom.

It is evident and experiment proves it to be so, that

1st. Two particles of solids of equal size and shape and of equal specific gravity (density) will prove equal falling.

But experiment proves not only this; it proves also that

2d. Two particles of solids of equal size and shape, but of unequal density (specific gravity) are not equal falling; but the particle of higher density will reach the bottom before the same sized particle of less density will reach it.

3d. Two particles of solids of unequal size but of equal density (specific gravity) are not equal falling, but the larger particle will reach the bottom before the smaller particle of same density will reach it.

4th. Two particles of solids of unequal size and shape and of unequal density may become equal falling, and they will become so, if the size of the particle of less density be so much larger to make up in size, viz: in positive weight (medium to penetrate the water and to resist its adhesion or friction on the way down of the particle of solid) what it lacks in relative gravity (density); globules one-eighth inch in diameter of galena are equal falling with globules of one-half inch diameter of quartz.

The shape of particles influences these results for so limited an extent, and in practice it can be controlled so little, that for all practical purposes shape can and may be neglected if the size alone be regulated.

The effect of a column of water without motion, and the effect of a vertical upward stream of water do not differ so as to result in an alteration of the before-stated four principles (axioms.) But the upward motion has the effect only, which a greater density of the liquid would have to retard the motion of all solids in their downfall. In a lighter liquid or in air the motion of solid particles would be accelerated comparatively; therefore motion must be imparted to air in order to impart to it the same rate of resistance as water possesses without motion.

General News Items.

THE Turks and Russians are rushing for good points for the coming struggle.

LARGE sales of horses for French light cavalry have been made in New York.

The river Duiper overflowed, and 20,000 people are homeless.

The German Parliament refuses to impose compulsory duties on iron and iron goods.

RATES of fourth-class freight between Chicago and New York have been advanced.

Tuz story that the Benders were killed by a party which pursued them from Kansas is revived.

An extensive conflagration occurred in Constantinople on Saturday. Six hundred houses were destroyed.

It is reported that England is negotiating with the Porte for the cession of the Suez canal.

EX-SENATOR WM. G. BROWNLOW, better known as "Parson" Brownlow, died on Monday at Knoxville, Tenn.

THE Internal Revenue receipts to the 30th of April show a gain of \$2,600,000 over the corresponding 10 months of last year.

THERE is not a single vessel at this port receiving wheat at present—a circumstance that has not happened before since 1875.

THE plasterers have at last accepted the terms of the Real Estate Associates, \$4 per day for 10 hours, and work is again going on at the company's new building on Montgomery street.

SAN FRANCISCO, with a larger paid-in banking capital than St. Louis, Cincinnati and Chicago combined, has only about a quarter as large a debt as the smallest sum of liabilities in the trio.

It is said that a bill will be introduced in the coming Congress reducing the army to 10,000. The Indian war is ended, and neither Sherman nor Sheridan believe it will be resumed.

HENRY WATTERSON has accepted an invitation to deliver the memorial address on Decoration Day over the graves of Union soldiers buried in the National cemetery at Nashville.

MORE Cheyenne warriors have surrendered at Red Cloud agency, and 40 other lodges are reported as at the mouth of Tongue river, coming in. Crazy Horse's band are on the way to the agency.

Luxury on the Rail.

The Difference.

We have been frequently asked: "What is the difference between a railroad dining car and a Pullman Hotel car?" That there is a vast difference is well known by those who have had occasion to use either; but the untraveled public are not fully advised as to the points of difference. The old-fashioned railroad eating-house, almost too well known; its peculiar, hastily-eaten meals have been partaken of by too many thousands to be forgotten. The dining car, then, is this well-known eating-house placed on wheels, attached to the train at the usual meal hours, and hauled along for 30, 40 or 60 miles, until the meal has been served, when it is set off on a side-track, and is by the next train hauled back to its starting point, and so it runs a few miles for each meal. To get meals in this or the passenger has to work his way through the train while it is under full motion—pass from car to car, running the risks of falling between the platforms, and finally finding the car at the rear of the train. Then comes the meal, which must be hurried through with to give chance for other hungry passengers to take your place, and you must force your way back to your seat, and again run the risks of your platform passage while the train is at full speed. In such cars you pay 75 cents for each meal, even if you take or need only a cup of coffee and a cracker. Bear in mind, in no case do these dining cars accompany the train from starting point to destination. They are always "cut off" and taken on as we have described. With the Pullman Hotel car the case is different in every respect. These cars are 60 to 66 feet long, have 16 wheels under each, are built strong, so as to insure steady, quiet running, without the usual unpleasant side motion. Each Hotel car contains, in the order named, the following compartments:

1st. A cosy, neat and clean little kitchen, fitted up with a range, an ice and meat box, rows of shelves covered with bright silver and glass ware, and all the appliances needed for preparing a sumptuous meal.

2d. A compact china and glass closet, in which is kept the table ware and table linen, cutlery, etc.

3d. A passage way, cutting off the kitchen and china closet from the rest of the car, and forming an air chamber to prevent the smell of the cooking victuals from reaching the saloon portion of the car.

4th. The grand saloon. This is fitted up with 12, 14 or 16 sections, with space for tables between each, and in these the meals are served. You, while on the car, own the space you occupy as much as your room at home, and no one can hurry you while at meals, nor are you forced to give it up to allow any other person to occupy it. At night, as if by magic, this saloon is changed into a boudoir, and here your couch is prepared, and here you rest yourself isolated, and as separated from your fellow travelers as you would be in your own bed-chamber.

5th. An elegant drawing-room, with room for six or eight persons to occupy as much as your room at home. In it you and your family or party of friends may be as secluded as you please, or you can slide open the end and have the company of those in the grand saloon.

6th. Charming arranged lavatories are partitioned off, and arranged in two distinct compartments for the separate use of ladies and gentlemen. These lavatories are supplied with pure water, clean towels, combs, brushes, and all the things one most desirably may desire for the perfect performance of an elaborate toilet.

7th. Then follow conductor's and porters' rooms, linen closets, etc.

It will thus be seen that this car is, as its name implies, a perfect modern hotel, with all of its appliances and comforts complete. This car is taken on at the commencement of the journey, and is part of the train to its destination. In it you get your sleeping compartments and your meal accommodations, while neither encroach upon the other. Envious dining-car employees, who are paid to decry this form of hotel car, cannot, with anything like truth on their side, give any valid or conclusive reasons for preferring the dining to the hotel car, and they only chatter in favor of their dining car because they are paid to do so. These hotel cars have been run from New York to San Francisco and back with the Emperor Don Pedro to San Jarrett & Palmer's party, that traveled at almost lightning speed—with many a party of California bonanza kings; and all join in pledging their honor that the cars are incomparable.

Two lines of these celebrated cars run between New

York and Chicago, and one line only between Chicago and Omaha. It may be needless to say that this last-named line runs over the steel track of the Chicago and North-western Railway. That these cars are attracting a large share of the California travel, both ways, might easily be conjectured. Any road deserves to be patronized that is enterprising enough to give the traveling public such facilities as are freely tendered by the Chicago and North-western Railway on its California line.

We have neglected to say that, in these hotel cars, the meals are a *la carte*—you pay for what you get, and nothing more; and that at very reasonable rates—*The Tribune*, April 7th, 77.

THE GRAND PACIFIC—This fine hotel, in the city of Chicago, cost \$1,300,000, and occupies an entire block. It is 130 feet high and has 500 rooms. It is a very elegant structure, and is a favorite resort for people from the Pacific coast, as everything is in the best style and all the arrangements are as complete as an efficient management and great experience can suggest. The building is specially secure against fire, as it was constructed with this object prominently in view, and every appliance known for the prevention of fire is at hand. In all its features the Grand Pacific has been guarded against the chief enemy of all large structures.

Mining and Other Companies.

Booth Gold Mining Company—Location

of works, Auburn, Placer county, California.

Notice is hereby given that a meeting of the Board of Directors, held on the thirtieth day of April, 1877, an assessment of five cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, No. 320 California Street, Room No. 5, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the fourth day of June, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on the twenty-fifth day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Directors, GEO. R. SPINNEY, Secy.

Office, No. 320 California Street, Room No. 5, San Francisco, Cal.

California and Arizona Mining Company—

Location of principal place of business, 501 Montgomery

Street, San Francisco, California. Location of works,

Mohave County, Territory of Arizona.

Notice is hereby given, that at a meeting of the Board of Directors, held on the third day of April, 1877, an assessment of two cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin to the Secretary, at the office of the company, 567 Montgomery Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid, on the thirteenth day of May, 1877, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the fourth day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, A. E. JEWELL, Secretary.

Office, 507 Montgomery Street, San Francisco, California.

California Fruit Growing Association—

Location of principal place of business, San Francisco, Cal.

Location of property, El Dorado county, Cal.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 14th day of April, 1877, an assessment, No. 4, of \$2.00 per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary at the office of the company, 331 Sansome Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 21st day of May, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday the 3rd day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, HORACE JONES, Secretary.

Office, 331 Sansome Street, San Francisco, Cal.

Consolidated Bonanza Silver Mining Co.—

Principal place of business San Francisco, California. Location

of works in Eagle and Washoe Valley Mining Dis-

trict, Ormsby county, State of Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 19th day of April, A. D., 1877, an assessment, No. 1, of 10 cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary at the office of the company, No. 19 First Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on Tuesday the 29th day of May, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday the 19th day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, WM. MARTIN, Secretary.

Office No. 19 First Street, San Francisco, Cal.

Dolores Consolidated Mining Company.

Location of principal place of business, San Francisco, California.

Location of works, Dolores Mining District,

Esmeralda County, Nevada.

Notice.—There are delinquent upon the following described stock, on account of assessment (No. 1) levied on the seventeenth day of February, 1877, the several amounts set opposite the names of the respective shareholders, as follows:

Name.	No. Certificate.	No. Shares.	Amount.
Blasdel, H. G., Trustee.	16	10,000	\$1,000 00
Blasdel, H. G., Trustee.	17	5,000	500 00
Blasdel, H. G., Trustee.	18	5,000	500 00
Blasdel, H. G., Trustee.	19	5,000	500 00
Drexler, L. P. & Co., Trustee.	8	25,000	2,500 00

PATENTED CAST STEEL SHOES AND DIES.

Guaranteed Cheaper than the Best Iron.
IMPORTANT NOTICE.
Reduction in Price from 16 Cents
to 12 Cents Per Pound.

Owing to our largely increased business, the present
low price of Iron from which our Steel is manufactured,
and the improved facilities for casting and forging,
we take great pleasure in announcing that from and
after this date we will supply our IMPROVED CAST
AND FORGED STEEL SHOES AND DIES FOR
QUARTZ MILLS at twelve cents per pound, delivered
at San Francisco or Sacramento, instead of sixteen
cents, as heretofore.

We also furnish Steel Plates for Blake and other Ore
Crushers, Steel Gut Gearing, etc., for Mills and Hoist-
ing Works, Steel Pan Shoes, Battery Cams and Tappets,
etc., etc.

Address all orders, with dimensions or drawings, to
CAST STEEL SHOE & DIE CO.,
59 Nevada Block, S. F.

PICKERING ENGINE GOVERNOR.

VALLEJO FOUNDRY, October 17th, 1876.

Messrs. NEYLAN & YOUNG, San Francisco,

Agents for "PICKERING GOVERNORS."

Gents:—The 10 two-inch Improved Speed Adjusting Governors I bought of you this year for my patent Straw Burning Threshing Engines give splendid satisfaction. They far surpass for regularity of speed any Governor that I have ever seen, and I have seen all the best kinds; I have seen the main belt fly off the pulley several times this season while threshing, and the engineer did not discover it, so perfectly was the speed maintained, until he was told of it; this I consider something wonderful; I consider the Governor absolutely perfect, so far as speed is concerned. I bought and put on to one of my engines a Shive Governor, to see which was the best, and after one season's trial I have no hesitation in saying they are far superior to any other Governor that I have seen or used. I wish you would send me the lowest price that you can furnish 25 Governors for next season's engines.
Yours respectfully,
J. L. HEALD.

The only Governor that has received awards at each of the International Exhibitions. American Institute Fair, New York, 1865, Two Medals; Mechanics' Institute Fair, Baltimore, 1865, Silver Medal; American Institute Fair, New York, 1869, Two Medals; International Exposition, Paris, 1867, One Bronze and Two Special Medals; International Exposition, Vienna, 1873, Medal of Progress and Decoration; International Exhibition, Philadelphia, 1876, Medal and Diploma.

THE GIANT POWDER COMPANY

Ask your special attention to their

IMPROVED GRADES OF POWDER, VIZ:

NO. 1 GIANT,

Now the Quickest and Most Powerful Explosive Compound in the World.

Price, 75 Cents Per Pound.

No. 2 EXTRA, a New Grade,

Which will hereafter be our second grade. It is of immense strength,

Far Surpassing any POWDER of its Class Ever Before Manufactured.

NOTWITHSTANDING ITS GREATLY INCREASED STRENGTH,

It will be sold at the price of the old No. 2, viz.: **50 Cents Per Pound.** Where a Powder stronger than ordinary No. 2 is needed, we invite a careful trial of this new grade.

No. 2. Our Powder of this Grade will Continue of the Strength of our No. 2 of Last Year's Make.

It is a Strong, Reliable and sure Powder, and will do excellent work.

SPECIAL ATTENTION IS CALLED TO THE REDUCED PRICE OF 35 CENTS,

At which we will hereafter sell this grade.

JUDSON POWDER. This New and Valuable Powder is Rapidly Coming into General Use as a Substitute for

Common Black Powder, to which it is in all respects far superior.

Descriptive Circulars forwarded on application. Price, 15 cents, or by car load 13 cents. In Cartridges, 2 cents extra.

Discounts as usual to the trade on our various grades of Powder.

Caps, single, double and tripple force, also, fuse of all brands always on hand.

Number 19.

An Improved Axle Set and Gauge.

On this page is shown an engraving of an axle set and gauge, which will enable any practical smith to get the height and dish of wheel, the taper of spindle, setting spindle for the dish, and adjusting spindle to any desired gather of wheels, without making a figure or diagram, or doing any guesswork, as rapidly as the gauge can be applied to the work in hand, securing perfect accuracy in the running of the vehicle.

Comparatively few vehicles on our public highways are free from the defects of imperfectly set spindles—putting the wheels out of line, changing the bearing of spokes and tenons, straining the whole running gear and producing hot boxes. The wagon is sent to a repair shop and here the painstaking smith, for want of a reliable axle set and gauge, is perplexed in giving the spindle the set required. True, if he has a draft board, rule and calliper, he can calculate what deviation the spindle requires; or if he has any of the old devices on hand for setting an axle, he can by aid of tables get at the needed change; or if he has forgotten the rule, he can set by guess, and by repeated heating, setting, measuring and hammering, get the spindles about right.

The test of a set of wheels is had by placing them (when fitted on axle), on a straight edge, then placing a square on the straight edge with the tongue against the face of the spoke, which must stand parallel with tongue of square if properly set on a plumb spoke. A second test of the wagon when turned out at the shop, is: The space between parallel spokes on opposite wheels, when measured at the fellow near the ground and on same spokes near the hub, must be exactly alike.

The apparatus under consideration consists of a one-inch by one-quarter steel bar, *A*, six feet three inches long, and an inch by three-sixteenths steel bar, *B*, three feet nine inches long, attached to the main bar, 13 inches from the right end by a straight standard, *K*, projecting four inches from one edge and three inches from the other. A screw passes through the center of this standard, serving as a pivot for the index and gauge bar, *B*, which at the left end is attached to the bar, *A*, by a slotted yoke and thumb screw. A scale is cut on the bar, *B*, to adapt it for any sized wheel, from two to five feet high. A vertical sliding rule, *J*, on the index bar, *B*, is designed to show the dish, while the graduated scale on the gauge bar shows height of wheel.

A movable arm-rest, *L*, with curved ends, projecting four inches from one edge and three inches from the other, fitted with socket and set screw, is attached to the bar, *A*, near the left end. It is designed to support the gauge on a true horizontal, over the center of the axle, the curved arm-rest, *L*, and straight standard, *K*, resting on the opposite shoulders of the spindles, while the index pointer of the taper-taker is placed over the end of the spindle to be set. The taper-taker, or graduated double calliper, is fitted with a movable arm, scale and graduated sliding gauge. It is moved on the index-bar, *B*, through a socket and held in place by a set screw. The short calliper and short ends of standards, three inches long each, are placed on the opposite edge of the bar, *A*. This is designated the "gather" side. Now for the application:

First. To get the height and dish of wheel: Apply the edge of the bar, *A*, fitted with the long standards, across the center of the wheel, below the hub shown, the straight standard, *K*, pressing against the tire, and the gauge-bar, *B*, against the spoke, over center of hub. Then slide the index-rule, *J*, to this point, which gives the dish, less half the diameter of the hub. To get this precisely, slide the index-rule, *J*, back to the right edge of the hub, and give the gauge-bar, *B*, the same dish at the edge as found at the center. This gives the exact dish of spoke from edge of the tire to center of hub.

Second. To get the taper of spindle: For convenience the taper-taker, or graduated double calliper, is removed from the gauge bar, *B*, and

applied to the shoulder of the spindle. It is then slipped down to the point thereof, as shown, when the true taper is shown on a scale graduated in sixteenths. The thumb screw secures the taper thus formed, and the taper-taker is thus replaced on the bar, *B*, ready for the third operation.

Third. Operation of setting the axle spindle for the dish: For convenience the bottom of the axle is turned up, and the gauge placed on it. The curved arm rest, *L*, and straight standard, *K*, rest on the shoulders of opposite spindles, while the graduated point of the calliper is fixed over the end, the gauge occupying a true horizontal line over the center of the axle, with the dish marked on the index rule, *J*, the taper of spindle shown on the calliper, the index point thereof indicates what set the spindle requires to insure a plumb spoke.

Fourth. To adjust the spindle to the gather: Move the gauge bar, *B*, until the scale on the sliding rule, *J*, indicates one-quarter of the gather desired. Apply the instrument horizontally to the front of the spindle, and bring the end of the spindle on a line therewith. For convenience and to facilitate a double test of the spindle, as to test and gather at the same time, transfer the gather adjusted as above to the short calliper on the gather side, secured in place by set screw. Then replace the set of the spindle for the dish on the taper-taker side, and the apparatus is gauged to test the spindle for

APPLICATIONS OF CARLTON'S AXLE-SET AND GAUGE.

set and gather, in two motions, insuring absolute accuracy of set and gather.

If it is desired to gather by the axle spindle instead of the wheel, set the short calliper, on the gather side, as much less than the taper of the spindle as the gather required. For instance, for a one-eighth gather, set the slide on the calliper one-eighth less than taper of spindle, (one-eighth), and set from front of spindle. Here is an example for working the gauge: Given, a four-foot eight-inch wheel, one inch dish, spindle 10 inches long, and one-quarter taper; the end of the spindle must be depressed one-quarter of an inch, as indicated in the gauge in four motions. First, place the apparatus on the axle; second, set slide-rule, *J*, on the index bar, *B*, at four feet eight inches; third, move the bar, *B*, at this point down one inch; fourth, set the index pointer on the graduated calliper down one-quarter, and the point thereof indicates a needed change of one-quarter of an inch.

The engraving shows all four applications in one view. The dotted lines on the lower axle indicate the curved shape of the same. The necessity for and convenience of this apparatus will be appreciated by every carriage-maker and blacksmith. It has been tested by some of the most competent smiths in the East. The instrument in the hands of an intelligent workman is a practical calculator of angles. Every result of the gauge has been mathematically verified. So practical is the machine that if the work is properly done, as indicated by the pointers, daylight cannot be seen through the measurements when the tests are applied, with the added advantage that with this axle-set any smith can turn out as many accurately-set axle-spindles in a day as he can heat and handle at the forge. The weight of the gauge is eight pounds, and it is substantially made for daily service. The gauge originated, and has been thoroughly tested in the shops of the Northwestern stage company, Wm. B. Morris, General Superintendent, Boise City Idaho, where economic original work and thoroughly accurate repairs on vehicles exposed to rough usage are of first importance. I. S. Van Winkle, 413 and 415 Market street, is the agent in this city.

A Fruit Pitting Machine.

There is now on exhibition in this city a machine for pitting fruit which is being examined with considerable interest because of the rapid work which its inventor claims it capable of accomplishing. We have not seen the machine in operation, but we are shown very emphatic testimonials of its efficiency in the hands of fruit manipulators who have used it in Oregon, where the inventor, Mr. Lillie, resides. The apparatus promises so much and there is such great need in our fruit drying and canning establishments for some mechanical contrivance which will reduce the great expense demanded by hand pitting, that we have made a little engraving of the machine so that we may give all interested some idea of the arrangement.

As the fruit drops from the trough, where it is shown in the engraving, it falls between springs or guides which are so adjusted that each fruit, large or small, shall be held centrally over two circular saws which revolve towards each other. When the fruit is in this position, the hammer, which is operated by an adjustable lever, (as seen in the engraving at the back of the machine,) falls and pushes the fruit down until it is caught by the saws. As the saws revolve toward each other they cut into the

working capacity is said to be 3,000 pounds of fruit per day. For this information concerning the machine we are indebted to Mr. H. Jones, who is the sole agent for this State. The apparatus is on exhibition at Mr. Trumbull's store, 419 Sansome street. Mr. Trumbull says he proposes to have the machine fully tested in public sight as soon as fruit becomes more plenty. Meantime he will be pleased to show it to all who may be interested.

Milling.

The working of ores with the varied and excellent foundry improvements and attachments, is usually comprehended under the misused word "milling," which is properly to be regarded as the popular coinage responding to a demand for some handier word than "beneficiating." The word milling would be an excellent one if beneficiating or amalgamating were purely mechanical, as is the case with free gold; but where chemicals come into play to suit varied characters of ores, milling should not be a mere working by recipe, just as a cook makes pies or cakes; yet such is too frequently the signification of the practice. In every mining locality it is a recognized fact that this subject is of an importance above all others, for upon it

depends even the existence of whole settlements; and invariably it is the cost and percentage to be obtained that presents itself to science and the practical metallurgist. Good results, where the results are in the shape of bullion, call for the keenest practical intelligence and enlightenment with all the aid of the books and of new experiments that are to be had. Really our greatest need is that kind of knowledge that will enable us to work our mines with the largest profit; and, for the want of this, many of our mines are idle, which in Europe would be worked with success and profit.

In many places on this coast where mines are worked, when the expenses of milling are paid after those of mining, and 25% or 30% deducted from the pulp assay, an embargo is placed on all ores that do not run above \$50 or \$60 per ton. In more remote localities where expenses are greater, ore is of no use unless it will work over \$100 a ton. Cost of working and percentage of gain vary greatly in different localities and on different ores; but it frequently happens that there is a great difference in this respect in the same camp, which is, of course, in a great measure due to the methods of manipulation. Many ores have been pronounced smelting ores on this coast, which could, with skill, be better treated by other methods. Because ores are refractory with quicksilver under unskillful hands, it is not necessary to conclude therefore that smelting or some complicated process is required. This is, however, too often the case. The remedy is in the hands of the owners, and consists simply in refusing to have anybody about the works who does not understand his business thoroughly. One half of the failures which have occurred have been due to the incompetency of employees; people who have been put in because of relationship to prominent owners or some similar cause. If stockholders took more interest in the affairs of the companies, and when they saw anything of this kind going on would enter a vigorous protest, there would be fewer failures and better work done. There are plenty of perfectly competent men who may be procured to take charge of works, without giving the position to some one who wants to learn the business at the expense of stockholders. There are plenty of good, experienced miners who unfortunately consider themselves also good metallurgists, and these men are more apt to mislead others because they mislead themselves. It by no means follows that because a man is a good miner he is also a good millman. Although the professions are closely connected, there is a great difference in the requirements. It is important to have a good miner but it is equally important to have a good metallurgist, who thoroughly understands his business in all its branches, and who, if anything goes wrong will know how to remedy it.

The war in Colombia is virtually ended.

Lillie's Fruit Pitter.

each side is kept up to the saw by means of the tail screw with its coil spring, but in pitting freestones these knives are let down so far as not to touch the pit as it passes down. The upper, or long knives, are sufficient for free stone fruits. The machine is operated by a crank which the operator turns with his right hand, and with the left hand he regulates the rolling of the fruit into the opening.

This interesting apparatus is put forth as a pitter of all stone fruits, and claims the sole ability to pit cherries successfully. Its average

"Comstock Papers."

The following from a recent number of the *Virginia Enterprise* will serve as an addition to the "Comstock Papers" published in this journal:

Yesterday morning the reporter was awakened from his matutinal repose by the sound of picks and shovels near, and within a few feet of where picks and shovels first sounded on the Comstock. A moment later he found himself at the old original Ophir dump, near the intersection of Carson and Howard streets, the wind flapping his shirt sleeves fitfully and musing his unkempt hair as he stood watching some Mexicans undermining the dump. It may be said, by way of explanation, that nearly the whole of the old dump was removed to macadamize C street last fall. To reach the bottom, therefore, only requires now the sinking of a few feet, where previously it would have been necessary to have sunk from 12 to 20. The Mexicans, to the interrogations of the reporter as to their actions, gave the following explanation:

During the season of 1861, when the great freshet visited Sacramento, the Ophir was being worked for the rich ore of the croppings. This was not to be reduced by the rude appliances of the day, but was to be sacked and shipped on the hurricane decks of mules to California. Each mule load was worth from \$1,000 to 1,200, so rich was the rock. At the time of that freshet, from 20 to 30 sacks of this ore had been taken out and was ready to ship. The flood came down through Ophir ravine like the waves of the sea, taking everything before it. Cabins and all sorts of mining works were swept away by its fury. It even took a brick building down on D street. The sacks of ore were never found afterwards. The leader of the gang, with hair and beard like the almond's snowy bloom, and who mined on the Comstock before it was ever seen by the original prospectors, said he was satisfied that the sacks were covered by dirt and debris near where they were digging, and where dumps had subsequently covered them still deeper. Now that the dumps had been so nearly removed, he expected to be able to find them readily.

The conversation having thus drifted into olden channels, and the company having been increased by the presence of John L. Moore, one of the veteran prospectors of the Comstock, the reporter drew his note-book and listened.

Mr. Moore (to the gray-haired Mexican)—Did you know Savariano?

Mexican—Yes. He mined up here (pointing toward the old Mexican works) 20 years ago.

Moore—He was a great prospector.

Mexican—Yes. He found this (meaning the Comstock); he and Moldonado. Then he found Cerro Gordo. He discovered ore out there at Austin, too.

Moore—Did you ever go with him on his prospecting trips?

Mexican—Yes. I was with him when he found Cerro Gordo.

Moore—Oh, ho! then you know something about the 40 loads of ore stolen from Moldonado?

The Mexican looked alarmed; glanced at the reporter, shook his hands, shook his head, and refused to talk any more. At a nod from Mr. Moore the reporter took the hint without waiting for a boot as a starting point, and left.

An hour later he made it very convenient to meet Mr. Moore and from him he got the balance of the story.

When the pioneers first came to this section they found Mexicans working the claim named after them, but which is now part of the Ophir mine. The ledge from which this ore was taken has never yet been found by the Americans. In those days one-half of the claim was owned by Moldonado, and was worked by Savariano. The ore was very rich, a single mule load being worth from \$1,000 to \$1,200. This was taken by pack mules to California by the way of Placerville. Some 40 mule loads had been taken out and prepared for packing.

Next morning it was found that the pack train under Savariano had departed in the night. The lead had been covered up and has never been found since. The only thing ever seen or heard of the train was by an early teamster as it was filing towards the mountain by Woodford's, and beyond Genoa. Savariano had played Moldonado false, had stolen the mules and from \$40,000 to \$50,000 in ore, and left the country. Instead of going through by Placerville, he kept along the eastern slope of the mountains, struck down by Aurora, thence through Mono into Inyo county, California. It was during this flight that the gold mines of Cerro Gordo, in Inyo county, were discovered, and the white-haired Mexican said yesterday that Savariano was in that section now.

A year ago last summer, Mr. Moore saw a Mexican walking over the section where the old original Mexican claim lay. He watched the man for an hour, as he appeared to be searching for something, but seemed unable to find the bearings. At last Mr. Moore interviewed and found him to be Savariano. He was then searching for the lead from which this rich ore had been taken, and which, on the night of the flight, had been covered up. Savariano at that time asserted, as does the old white-haired Mexican who was with him while here and who went away with him, that the rich lode from which that ore was taken has never been discovered, but remains to-day on the Ophir ground as it was left at that time. Savariano, when here, tried to get a lease of the ground of

the Ophir company, but did not succeed. The old Mexican says things have changed so that he cannot tell for sure where the lode lay, but that Savariano knows where it is, and can uncover it in a day or two.

There are several things which go to corroborate this wonderful story. The sudden disappearance of the Mexicans and their pack mules is well-known to all early Comstockers. This was followed by a cessation of work on the claim and desertion of the premises.

Concentration in Montana.

The Butte (Montana) *Miner* gives the following description of Olin's concentrating works which are in successful operation:

Brief mention has been made of the condition and progress of these works from time to time in these columns, but no attempt to give anything like a detailed description of the process now in successful operation. A visit by our reporter last week found the works running, and appearances in and about the concentrator indicating a degree of activity and bustle rather surprising. The numerous "dumps" of ore waiting to be treated and the piles of concentrated ore lying outside, being sacked up and prepared for shipment, showed that something was being accomplished inside the building. But before entering upon any description, it may be well to state briefly how, and under what conditions, the proprietor has brought these works to their present state of perfection. Mr. Olin commenced operations last summer, with very limited means of his own and at a time when the financial condition of the camp and its business was not as good as now by a long way. The first idea of starting up with hand jigs was carried out, and after a thorough trial had to be thrown aside for various reasons, the principal one being that the process was too tedious and necessitated too much labor. Then plans were drawn by Prof. Knabe for an automatic jig, which is the one now in operation, made on the ground and substituted for those discarded. During this time the weather was cold and stormy and the ore on hand and at the mines was covered with ice and had to be dried before it could be worked. A furnace or kiln was then erected, which occupied more valuable time and cost something besides. Before going further it should be stated that this furnace is not used only in case the ore has become wet from exposure to storms, or when taken directly from the mine without having lain in the sun any length of time. In the latter case exposure to the sun and wind will dry the ore sufficiently in a few hours and the furnace is not needed. The statement published some time since that the operation of heating the ore injured its quality is incorrect, the action of the heat not being strong enough to affect the value of the ore a particle. We understand the statement operated quite seriously at the time against Mr. Olin, and there being no foundation for the opinion it should be corrected.

In connection with putting in the automatic jig several other additions had to be made to the works and when these were completed it was well on to spring. And thus the owner has been put back in one way and another in getting under way till within the last few weeks.

The works are on a small scale but will prove of great advantage to owners of copper mines this season. Our description of the process will be brief, it not being necessary to enter into minute details. A visit to the works will satisfy any person that they are doing good work and be more satisfactory than any statement we might write.

In the first place, after the ore is pretty thoroughly dried in the sun or otherwise, it is put through a Dodge crusher, a spout from which carries it to a pair of Cornish rollers, (patterns for which were made by Mr. Olin and the rollers cast at the Butte foundry,) the ore dropping from the rollers into an elevator box and carried up and deposited into a revolving screen. This screen is very fine (No. 40), and takes out what is called the slimes, which are run off by themselves and treated by hand, mention of which will be made further on. The balance of the ore passes through this revolving screen (it being on the same principle as those used in grist mills in cleaning wheat), and from here is conveyed to another screen or bolt (on the same principle again as those in grist mills), having three grades of mesh. In passing through this screen everything but sticks and what may not have been crushed to the size of a duck shot in going through the crusher and rollers, drops into a bin and is again taken up by elevators and deposited into a hopper over the jig, where it goes through the process of condensation and separation, the concentrated ore being deposited on the floor and the gangue passing off and out of the house through a spout with the water that has done its duty in the operation of dressing. We are not well enough posted to give an intelligent description of the *modus operandi* of this jig. The principle of the process is something similar to that of a grizzly in saving gold. As stated previously, the pattern for the jig was furnished by Prof. Knabe, he having seen some like the one in use here in Germany. It does its work well and is considered as good as any pattern which is manufactured in the country.

The slimes, which were spoken of above, contain about one-fourth of the whole value of the ore as originally introduced into the dressing process, and the treatment of them by hand through tailing sluices is the only serious draw-

back in the whole operation. The works are now dressing about seven tons of crude ore every 10 hours, and the labor required to dress the slimes amounts to as much as all the other force employed, three men being kept steadily engaged, and then not being able to keep the bin clear. It is the intention of the owner to make this part of the business also automatic, doing away with the labor and expense of three hands, and also doing more rapid work. He has a plan already perfected by which he thinks he can accomplish this, and his perseverance and energy will doubtless carry the point.

The works are only run during the daytime at present, but in the course of a week another set of hands will be put on and steam not be allowed to be turned off day or night except for cause. To give an idea of the successful treatment of the ores and the advantages secured to miners in the operation of this concentrator, it may be said that after sorting out what will bear shipment at the mines—35% to 40% ore—the remainder is called second-class and would be utterly worthless and unmarketable unless concentrated. This second-class ore is concentrated to about one-half its original weight and bulk, the product carrying from 36% to 40% in value—about the same as the first-class ore after being carefully sorted. Perhaps two-thirds of all the ore taken out is second-class, or under 30%. There are hundreds of tons of this ore on the dump at the different lodes now working. The concentrator is now running on a lot of 37 tons from Discovery claim on the Parrott. This lot assayed 28%, which would not do to ship and therefore had to be dressed. Another lot of 600 tons from the Poznainsky claim, Mountain lode, is being delivered, which will be put through next. Mr. Olin informed us that 400 or 500 tons more from the Parks claim will be forthcoming when needed.

Now, that the works are proving a success and giving satisfaction in every particular, we hope that the owner's efforts will be duly appreciated and given a fair and liberal support, which we have no doubt he will receive.

As before stated, the enterprise is of great advantage to copper miners, securing to them fully one-third more receipts for their labors, and, in benefiting the miners, must necessarily contribute something to the general welfare and progress of the camp.

The Idaho Mine.

The Grass Valley *Union* gives the following description of this famous California mine:

The Idaho quartz mine was located May 8th, 1863, by Thos. J. Pegg and others, numbering 31 persons, mostly residents of Grass Valley and vicinity, and recorded upon the county records of Nevada county, comprising 31 claims of 100 feet each, and upon the easterly extension of the Eureka quartz lode. By proper transfers, the mine became vested in the following persons, to wit: Thos. J. Pegg, Wm. Young, Dibble & Byrne, J. Fricot, H. D. Cady, T. Findley, M. P. O'Connor and E. W. Maslin, who proceeded to levy assessments for the purpose of prospecting the mine. Previous to this time, however, there were other parties, one Edwards and others, who laid claim to the ground, but failed to establish that claim in court, and consequently the title became vested in the above named parties. The first work was done by sinking a shaft nearly in the center of Wolf creek, and now about opposite the present company's office. Work was prosecuted with vigor during the seasons of 1863-4, but finding the rock very hard, it was finally concluded to stop the work there and sink upon the side of the hill, where the present heavy pumping machinery was erected two years since. During all this time, about two years, assessments were being levied, and, as is often the case in mining operations, things looked pretty dark for the company. As a consequence, the property changed hands more or less; but to the honor as well as the profit of some of those plucky men, they struggled manfully through with the burden of assessments. But as results have proved, they showed their wisdom in holding on, and to-day are quietly reaping upon their hard won, but well won laurels. Such is pluck, especially in mining enterprises.

The shaft spoken of above was commenced July 5th, 1865, and work prosecuted upon it until February, 1866, when the work was stopped for about 18 months, on account of the difficulty of collecting assessments from some of the owners in the mine, the shaft having been sunk 120 feet, and a cross-cut driven into the foot-wall 70 feet. It was not then an incorporated company. Up to this time, there were paid in and expended upon the work over \$21,000. About September 1st, 1867, articles of incorporation were entered into, and a code of by-laws framed for the government of the company. The first regular meeting of the Board of Trustees was held September 6th, 1867, at the office of the company, Findley's banking house, Grass Valley, and the following Trustees elected as the first officers: John C. Coleman, President; Wm. Young, Vice-President; Thomas Findley, Treasurer; and M. P. O'Connor, Secretary; to serve for the first three months; and Edward Coleman, Esq., was appointed Superintendent, and at the first annual meeting was elected President, and has continuously served in those positions in a most efficient manner until the present time, except for a short interim, in which he was absent from the State. An assessment of \$1 per share

was levied upon the capital stock of the company, at the time of the first election, aggregating \$3,100, and work resumed upon the shaft spoken of above, and continued until a depth of 300 feet had been attained, when the drift was run toward the Eureka mine and pay ore found.

During the progress of this work the shaft was continued to the depth of 500 feet, when the pay shute was struck in the shaft. From September, 1867 up to September, 1868, the sum of \$18,600 was levied and collected in assessments. A 15-stamp mill was commenced in July and completed in the fall of '68, and upon July 4th, 1869, the first dividend of 2½% upon the capital stock was declared. During the year 11 dividends were paid to the stockholders, amounting to the sum of \$170,500, and aggregating 55% upon the capital stock of the company. During the last eight years, and including the first four months of the fiscal year, the mine has paid a net profit to the stockholders of \$2,123,570, the ninety-second dividend having been declared on the 2d of April of the present year. In 1872 the 15-stamp mill of the company was remodeled, and its capacity increased to 35 stamps, with all the latest improvements in gold saving, at a cost of \$38,000. In 1872 a new hoisting shaft was commenced, six by 20 feet within timbers in size, and having three compartments. This shaft is now down 1,116 feet on the incline, at a cost of \$104,000, as we find by reference to the annual report of the Superintendent. The hoisting works connected with this shaft cost \$30,000.

The original shaft sunk upon the mine is now used as a pump shaft, with the machinery and pumps of sufficient capacity to successfully contend with any amount of water that may be encountered. The repairing of this shaft and the erection of the pumping machinery and the fire-proof brick building within which it is contained, cost \$36,000. Everything about mill and mine is in fine condition, and under the able management the future looks bright for a long time to come. A peculiarity noticeable in the Idaho mine is that there is no surface croppings of the vein except about 60 feet at the west end of the location, but the croppings or rather the top of the ledge sinks into the earth at the same angle as the pay shute. For example, the vein pitches southward at an angle varying from 73° to 51°, while the pay shute which came into the ground from the west and was struck on the 300-foot level, pitches eastward on the vein at an angle of 33° and still continues at that angle at the depth of the mine. This shows the importance of not always depending for a ledge on merely surface croppings; but that where well defined croppings are found, that it is fair to assume the ledge may hold its course underground, and that it may be struck at varying depths—those depths to be judged by the angle of the pay shute, if such be found at the surface croppings of the vein. On next Monday the Idaho will pay its regular monthly or ninety-third dividend. It will be \$7.50 per share, aggregating \$23,250.

San Diego Mines.

The San Diego *World* has these notes from Julian and Banner districts in that county:

The Helvetia mill has been running steadily on San Diego ore for the last week, and will clean up about \$1,500. The ledge is about two feet wide, and continues down to the bottom of the shaft, one hundred feet from the surface.

The Ready Relief mine is being worked by Messrs. Ring & Cundy, and is turning out rich ore, and looks better than ever before.

The Tom Scott mine, purchased by John P. Sanborn, has commenced operation under the supervision of J. M. Beach, J. W. Munday acting as foreman. As to what their intentions are in regard to sinking, or stopping, we are not informed.

The Centennial mine, under the supervision of Morgan, Vale & Co., is moving slowly. Prospects not very flattering.

It is understood that the Golden Chariot will commence operations as soon as the assessment, levied lately, is paid.

It is stated that the Stonewall will soon commence operations.

It stormed very hard in Julian last Sunday and Monday, with good rain and a light fall of snow.

GRAVEL MINES.—The burgs of Liberty, Lowell, and Remington Hills are beginning to show marked signs of prosperity. The mines already opened at these places are all paying dividends, and with the numerous miles of large deposits of gravel, which are known to exist in that vicinity, all of which it is thought will pay well to either drift or hydraulic, and from the large increase of prospecting which has been put in progress since the reduction of miner's wages, we have good reasons to predict that in all probability in less than two years from now there will be a large number of men employed in that locality, in working some of the richest and most extensive gravel mines that now exist in either Placer or Nevada counties. Several of the tunnels which are now under headway are being run by contract, the parties constructing them receiving for their labor a deed to one-half the ground, when the gravel in the bottom is tapped. There are two more companies talking of letting their ground on the same lay-out, and as each claim embraces considerable ground, there is still a chance for several more enterprising miners to get in possession of what the present prospects indicate to be a rich mine, at a very light expense.—*Dutch Flat Forum*.

MECHANICAL PROGRESS.

Balancing Buhrs.

John W. Hopkins, a millwright of Wilmington, Delaware, gives the *Mill Stone* a straightforward and practical method of performing this much discussed operation. He says: As "centrifugal force is always as the specific gravity, and the square of the velocity," therefore, every heavy block in the buhr below the horizontal plane of the cock head, throws up while running and down while standing, and every heavy block above the cock head throws down, both when standing and running, if not balanced by blocks of the same size and weight on the opposite side. This can be demonstrated to the eye as follows: Undo the connection between the throttle-valve and governor of a steam engine; substitute a wooden ball for one of the iron ones, and start the engine; the iron ball will reach the horizontal plane with a less velocity than the wooden one. But when we come to apply these principles to practice in the balancing of buhrs in the usual way, we find that they don't always work, and we wonder where is the mysterious influence which sets at naught the laws of gravitation and centrifugal force. The influence is in the irons. The cock head may be off the truth. Chalk will show that. It may be in the drivers; but far oftener it is where least expected—in the pivot bearing which rests on the cock head. Now, to get at the root of the evil, we must begin at the beginning, by asserting that not one in a hundred of these are right when they leave the machine shop. The usual way to find the center is by squaring, plumbing, measuring, etc. They are then taken to the drill-press, blocked up and bored with a flexible revolving drill, and not one in a thousand of borings are concentric with the circular part of the balance rynd. The right way is to make two cast-iron brackets for the purpose, bolt them on the face plate of lathe, turn off true, clamp on your balan rynd to these so as the inside circle and lower edge of rynd is true to the chalk; bore or turn out with a rigid fixed tool your circular and bearing, turn off the edge of rynd and turn inside of rim, true down to about three-quarters of an inch from edge. Now all this may be done and the rynd put in true by the millwright; but if the miller or dresser takes more off one side than another in dressing his buhrs, the mill in time becomes unbalanced. The true plan is to bore and turn a light cast-iron wheel or plate with an oblong hole, with set screw to receive an arm with marking point; fit this into the turned mouth of the balance rynd; to be used only to try if the millwright puts the rynd true, and if the miller dresses equally all around, this can be done cheaply and simply; and until this is done, none but the most expert and persevering of men will be able to keep buhrs in good order, the average miller will be humbugged, and poor flour and dyspepsied stomachs will be the result.

AUTOMATIC FURNACE DAMPERS.—Iron describes Mr. J. Watton's invention for regulating dampers of boiler furnaces. It consists of a self-acting apparatus constructed as follows for opening and closing the dampers of steam boiler furnaces. Over the furnace flue in which the damper works, is a hollow cylinder containing a long piston or ram, to the bottom of which the damper is connected. The damper and ram are kept in their raised position by counterbalance weights. A pipe from the steam boiler opens into the hollow cylinder, and in the course of the said pipe is a spring safety valve. When the steam boiler is working at its normal pressure, or at a pressure less than that which the safety valve is regulated to bear, the damper is kept in its raised position by the counterbalance weights, and the furnace flue is open. When, however, the steam in the boiler attains a pressure greater than that which the safety valve is regulated to bear, the safety valve is lifted, steam enters the hollow cylinder and depresses the piston or ram, and the damper and the flue is closed or partially closed. On the pressure of the steam in the boiler being reduced to its normal working pressure, the safety valve closes and cuts off the steam from the hollow cylinder, and the counterbalance weights raise the damper and ram, and the flue is again opened.

RAPID STEEL RAIL ROLLING.—The Scranton, Pa., *Republican* gives an account of rolling-mill work which the world is challenged to beat: "Last week the steel rail mill of the Lackawanna iron and coal company, in the usual 11 turns on a 50-pound rail 30 feet long, did the following work, which is considered one of the most extraordinary on record: 'Total number of rails rolled, 6,173; average per turn, 561; total tonnage during the week, 1,377.18; average time rolling each bar during entire week, including all stops during and between turns, 77 seconds; best single-turn rails, 740; best double-turn rails, 1,414; actual rolling time of above, consecutive, 1,414 bars, 23 hours, 43 seconds—average 60½ seconds per bar; 1,414 bars equal four miles and 90 feet of track. Greatest speed accomplished, 109 bars in 97 minutes, a little less than 53½ seconds per bar; 6,173 rails will lay 17 miles 2,835 feet of track.' On the above figures the officers and men of the mill make the following claims and challenge comparison: 1. To have rolled the largest number of rails yet rolled in the world on one rail train in one

week. 2. To have made the largest tonnage ever made on equally light rail in one week. 3. To have rolled the largest number of rails yet rolled in 12 hours. 4. The same claim as to 24 hours. Taking the above as an average the company, using both its mills, could roll rails for a double track to Pittsburg, a distance of 480 miles, in 27 weeks. This enormous amount of work turned out at No. 2 mill seems all the more when we compare it with that done at No. 1 mill on iron, now having the same capacity as No. 2, when the first Delaware, Lackawanna & Western track was being laid. The distance from Scranton to Great Bend is 52 miles, and it took the mill already mentioned nearly six months to roll the rails necessary, which could now be supplied in three weeks."

PETROLEUM FOR PRIMING OF BOILERS.—A paper "On the Priming of Steam Boilers" has been written by Mr. W. Major. The author draws attention to the great uncertainty which prevailed as to the cause of priming. The case of the *Serapis* was mentioned, the speed of which ship, through priming, was reduced from 13 to nine knots. The author then stated what he thought was the cause—friction of steam globes against impurities floating in the water. To overcome that, lubrication was needed. Tallow and oils had been beneficial for that purpose, but unfortunately had produced graver evils. Having tried many lubricants, the author found the purest rectified petroleum a perfect remedy, and he enumerated the advantages gained. He then explained his mode of application by reference to drawings, and stated the satisfactory results. He then mentioned two cases of collapsing of flues, in consequence of thick coatings caused by fatty and other particles carried over from the surface condenser, and preventing the access of the water to the internal parts of the boiler. He considered that this collapsing of flues caused the disappearance of many steamers which were never heard of again. He pointed out, in conclusion, that the use of rectified petroleum would not give rise to such accidents.

CASTING A BRONZE.—A short time ago, after the Italian residents of New York city had raised a nucleus of \$2,800, almost a penny at a time, the Italian sculptor, Turini, turned over to George Fisher, the founder, a colossal plaster bust of Joseph Mazzini, which was successfully recast in bronze. The *Iron Age* says it took two months to prepare for the casting. Into one of the halves of a great iron mold, filled with plaster and molding sand, the plaster cast was lowered, face down, and an impression of half the bust was taken. Exactly the same process was gone through with for the impression of the back of the bust. Both sides of the mold were then locked together, with the cavity left by the plaster cast filled in with a core of sand. The whole great mold was then baked until the back and front impressions of the cast were hard and clear, and the cast itself was reduced in the sand core, also baked hard and dry. Then came the delicate operation of shaving the impression in the mold and the core also, so as to leave a space between the core and the mold in which the molten bronze was to be run. After this had been accurately and perfectly accomplished—and it requires no little care thus to shave down the delicate features of a likeness—the core was hung in its place by bars and wires of iron, and the great mold was lifted to the side of the furnace.

MACHINE DRILLING IN MINES.—Sir G. W. Denys writes as follows: "Does boring by machinery pay? I answer decidedly, yes, wherever you have plenty of water-power and a long distance to go. I do not hesitate to affirm that I have driven 550 fms. with the borer, in one-third of the time, and for half the money, it would have cost to drive the same distance by ordinary hand labor. I am, indeed, afraid to hazard an opinion as to what it would have cost to drive by hand labor, for at the bottom I do not believe it could or would have been driven at all. Further, wherever extensive mining operations are intended, whether machine drills are to be used or not, an air compressor put up at the commencement, will pay for itself five or six times over."

USING SUPER-HEATED STEAM.—Mr. A. M. Clark, of England, has an invention for generating and utilizing highly super-heated steam. In a circular furnace is suspended one or more series of hollow spheres connected to one pipe, from which the generated gas escapes to an engine, and down which passes an internal pipe conveying water to be "decomposed." The spheres are made very strong, and the inventor claims that the "electric" gas produced from evaporated water possesses unlimited expansive force, which has not hitherto been made subservient to the will of man. The quantity of fuel needed is, he says, "out of all proportion" less than that needed to generate steam for the same amount of power. The specification describes an engine for using the "gas."

COMPRESSING STEEL.—M. Considere read a paper on the 30th of March before the French Saint-Etienne Association of Mining Engineers on the subject of "Compressing Melted Steel," which has been experimented on at Chaleassiere for the past twelvemonth. The results of experiments conducted on more than 100 tons of ingots enabled the author to affirm that steel castings never exhibit blow-holes when solidified under sufficient gaseous pressure, acting freely on the inner mass of the steel.

SCIENTIFIC PROGRESS.

Chinese Buying Science.

We read in English papers that the Chinese have bought out an English scientific establishment, and propose to export it to China. The account is as follows: "The gentlemen in this country identified with the promotion of Western knowledge in China, having been much impressed with the popular science lectures, which have been for some years past delivered at the Royal Polytechnic, in London, by Mr. J. L. King, F.G.S., determined a short time since to purchase the whole of the costly apparatus necessary for inaugurating similar lectures at Shanghai, and on Wednesday the Chinese Ministers and suite visited the institution in Regent street, to witness some of the most interesting phenomena connected with the polarization of light and other branches of optics, as shown by a new apparatus intended for an institution at Shanghai. The demonstrations were conducted by Mr. King, who delivered a brief lecture explanatory of the scientific principles which determine the phenomena, and who stated that the occasion derived its chief interest from the fact that it marked an awakening in the Chinese mind to the importance of scientific institution. The Chinese institution owed its origin mainly to the influence and exertions of Sir Walter Medhurst, lately our consul in Shanghai, who was Chairman of the Shanghai Committee, and Mr. Fryer, who acts as honorary Secretary. Their views have been energetically supported by our ambassador, Sir Thomas Wade, and by many of the leading mandarins, among whom may be mentioned Li-Hung-Chang, whose name has a European celebrity, Feng-Chu-ju-Taotai, of Shanghai; Hsu-Tschu-Tsun and his sons, who are well known throughout their own country for their technical skill and scientific enlightenment, and by many others who favor the importation of Western knowledge of every kind as calculated to render the most important service to their country. The design of the new institution is to make a first step towards satisfying this patriotic aspiration. A building has recently been erected at the city of Shanghai, within which lectures are to be given and interesting apparatus and processes shown; and likewise a reading room, provided with suitable works, is already in active operation."

THE DEPTHS OF THE SEA.—According to the late explorations of the English, German, and United States governments, it has been proved that the average ocean depths in the southern hemisphere are less than those of the northern hemisphere. The greater range of water surface in the southern hemisphere is, therefore, in a measure, compensated for by its shallowness. It has been a question how, considering the great apparent preponderance of land in the northern hemisphere, the center of gravity of the earth could coincide with its actual center, if such be the fact. These contours of the ocean-bed point to a possible solution. The greatest recorded depth in the southern ocean is 17,000 feet, while in the northern oceans 27,000 and 23,500 were found respectively in the Pacific and Atlantic. A published report of Captain Evans' remarks before the British Association, says: "The general surface of the sea-bed presents in general to the eye, when graphically rendered on charts by contour lines of equal soundings, extensive plateaux varied with the gentlest of undulations. There is one great feature common to all oceans, and which may have some significance in the consideration of ocean circulation, and as affecting the genesis and translation of the great tidal wave and other tidal phenomena, of which we know so little—namely, that the fringe of the sea-board of the great continents and islands, from the depth of a few hundred feet below the sea-level, is, as a rule, abruptly precipitous to the depths of 10,000 and 12,000 feet. This grand escarpment is typically illustrated at the entrance of the British channel, where the distance between a depth of 600 feet and 12,000 feet is in places only 10 miles."

FORMATION OF MINERALS.—Hartley has made further examinations of the liquids contained in mineral cavities. He finds, says *Harper's Magazine*, that the liquid carbon dioxide present varies considerably—from 27.27° to 33.7° C.—in its critical point in different mineral specimens, often varying in different cavities in the same mineral specimen. The presence of this substance in sapphire and topaz leads him to the supposition that these minerals may have been formed by the action of aluminum fluoride or chloride upon calcium carbonate at high pressures, producing alumina and carbon dioxide. Where water is also present in the cavity it would seem that the reaction had taken place in presence of moisture. As to the diamond, the author thinks that this mineral is the result of the action of reducing agents upon very highly compressed carbon dioxide at temperatures above its critical point—a condition of things which suggests a new direction for speculation and experiment.

It is said the fuchsia in its native country, Chile, runs into varieties as freely as blackberries do here—so much so that it is extremely difficult to decide what is a species and what a variety.

DARWIN'S CONCLUSIONS ON PLANT FERTILIZATION.—In Mr. Darwin's latest work of the conclusions reached, the first and most important is, that cross-fertilization is generally beneficial, and self-fertilization injurious. This is shown by the difference in height, weight, constitutional vigor and fertility of the offspring from crossed and self-fertilized flowers, and in the number of seeds produced by the parent plants. The advantages of cross-fertilization do not follow from some mysterious virtue in the mere union of two distinct individuals, but from such individuals having been subjected during previous generations to different conditions, or to their having varied in a manner commonly called spontaneous; so that in either case their sexual elements have in some degree differentiated. Again, the injury from self-fertilization follows from the want of such differentiation in the sexual elements. Thus, when plants of the *ipomoea* and of the *mirabilis*, which had been self-fertilized for the seven previous generations, and had been kept all the time under the same conditions, were intercrossed one with another, the offspring did not profit in the least by the cross. On the other hand, as showing that the benefit of a cross depends on the previous treatment of the progenitors, plants which had been self-fertilized for the eight previous generations were crossed with plants which had been intercrossed for the same number of generations, all having been kept under the same conditions as far as possible. Seedlings from this cross were grown in competition with others derived from the self-fertilized mother-plant crossed by a fresh stock; and the latter seedlings were to the former in height as 100 to 52, and in fertility as 100 to 4.

A NEW ERA IN TELEGRAPHY.—Prof. Loomis, of Washington, who has given to electricity and its uses much study and thought, says the time is not far distant when telegraphing will be carried out by means of aerial currents without the aid of wires or poles. He has already, he says, communicated with his assistant, who was 12 miles away, by means of an aerial current. The current was reached by flying kites a certain height at each point, the string used being a copper wire. When both of the kites would be at the same altitude and in the same current, he has, by means of an instrument attached to the ground end of the wire, sent to and received messages from his assistant, 12 miles away, there being nothing but an aerial connection between them. Prof. Peters, in an article on the telephone, written after he had witnessed its first performance, says: "The telephone of today probably bears to the telephone of the future about the same relation that Fulton's little steamboat bore to the magnificent floating palaces that now ply on our lakes and rivers, or to those nobler embodiments of human skill, which have reduced the formidable Atlantic voyage of our grandparents to an average ten days' trip."

A TESTIMONIAL TO DARWIN.—On his sixtieth birthday, Darwin was presented with an album, a magnificent folio, bound in velvet and silver, containing the photographs of one hundred and fifty-four men of science in Germany. The list includes some of the best-known and most highly honored names in Europe. He likewise received on the same occasion from Holland an album with the photographs of two hundred and seventeen distinguished professors and lovers of science in that country. The German album bears on the handsome title-page the inscription: "Dem Reformator der Naturgeschichte (To the Reformer of Natural History), Charles Darwin."

EVAPORATION OF NITRO-GLYCERINE IN DYNAMITE.—According to recent investigations of Captain Hero, of Vienna, it appears that a specimen of dynamite made in 1871 lost in five years 2.2 per cent. of its nitro-glycerine, and another sample manufactured in 1872 lost in four years 1.52 per cent., through evaporation. The conclusions are that regular times should be fixed as limits for the employment of dynamite supplies, and that, when the material is kept beyond these periods, it should be replaced by fresh. It is also suggested that, to allow for this loss, a larger proportion of nitro-glycerine than the percentage now employed (ranging from 71 to 73) should be introduced in dynamite.

TRANSIT OF VENUS.—Progress is reported at the Greenwich observatory in reducing the observations made on the last transit of Venus. Two of the most recent calculations required the use of 3,000,000 figures. The French attempts at obtaining new figures for the sun's distance by the study of the photographs taken during the transit, have been reported as turning out badly; it is even doubtful whether the photographs can be used at all for this calculation. Better results are hoped for at Washington from the photographs taken by the American expeditions, but the work proceeds very slowly because the appropriations by Congress were much smaller than had been expected.

DISTRIBUTION OF PLANTS.—From a sketch of the tropical forest of Hampshire, England, by J. Starkie Gardner, we learn that tropical plants, like the palm, cactus, and aroids, grew in company with the beech, oak, elm, maple, and laurel in the eocene period. Heretofore the accepted theory has been that the temperate plants did not make their appearance before the miocene, having migrated from America by way of Siberia. These discoveries will weaken the credit of this theory of migration.

TRANSVAAL has been annexed to the British empire.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

ALPINE.

THIS ADVANCE.—Alpine Chronicle, May 5: We have nothing new in regard to this mine. It continues to prospect well. Although in over 100 feet of good ore the foot wall has not yet been reached. We can assure our readers that there has been no over-coloring in regard to this mine. It will soon be a great wealth.

PROF. THOMAS PRICE, of San Francisco, and Mr. Hughes, Superintendent of the Blue Tent gravel mine, in Nevada county, arrived yesterday at the Exchange mill, where they are the guests of Manager Chalmers. To-day they have been inspecting the mines in Scandinavian canyon in the interest of English companies.

AMADOR.

MECHANICS.—Amador Ledger, May 5: Work is temporarily suspended. The result of the last crushing did not come up to expectations. It is the general impression, however, that when the affairs of the company are straightened out, mining will be resumed. There is any quantity of rock in sight, and the drilling depth to which the mine has been prospected—between 100 and 200 feet, we believe—is hardly a sufficient test to justify the abandonment of the claim.

OLIVE.—Favorable reports continue to reach us from this mine. The ledge is now from 6 to 7 feet wide. This, it is thought, is not the full width of the ore body, as indications favor the opinion that quartz exists in the hanging wall. The rock presents a very uniform appearance. So far the yield of gold has paid for the sinking and putting up the works, which is a rare occurrence even with mines which have turned out enormously rich. A run of \$10 per ton will pay expenses in the present sinking. The Isonanza mill will be kept running for the next three months on Olive rock.

KENNEDY.—The Kennedy will be started up on Monday. Mr. Fleming, who is placed in charge of the works is already here making his plans for the future. Work will be confined to prospecting by sinking the two new shafts commenced last summer.

THE MONTERICHARD.—Amador Dispatch, May 5: We understand the proprietors of the Monterichard mine have commenced hauling rock from their mine to the Onida mill for the purpose of having it thoroughly prospected and creating a mill of their own. They contemplate having several hundred tons crushed, and they are confident that it will pay handsomely.

BUTTE.

BIG BAR CLAIM.—Oroville Mercury, May 4: On Saturday last week, the Trustees of the Big Bar claim took a trip up the north fork to their claim. They paid \$10,000 for it the 1st of January, and have expended some \$3,500 in sinking it up. They now have two chiefs and 1,000 feet of good iron pipe, and 1,400 feet of flume. They have run but a short time. Some days ago they were offered \$30,000 for their claim by parties below, but as they have a good thing, they propose to hold on to it for the present at least. On the clean-up the other day, they were more than pleased, having got double the amount expected. They supposed if they got \$1,000 out of the small piece of ground washed, they would be doing extremely well; but to get double that sum was a long time that the intelligence of a big clean-up scarcely provokes comment, and people have come to regard enormous returns from that mine as a matter of course. The crushing of 85 tons of Champion ore, just completed, yielded in the neighborhood of \$9,000—an average of over \$100 per ton. And that is not in excess of former returns from the same quantity of rock, not to mention the fact that the mine has been making for years. We have frequently charged the State to "bait" our "Champion," but West Point still carries the lead for having the richest quartz ledge in the country.

CALAVERAS.

BIG CLEAN-UP AT THE CHAMPION.—Calaveras Chronicle, May 5: The extraordinary yield of the Champion mine at West Point, owned by Messrs. Haskin & Hadler, has been such a regular thing for so long a time that the intelligence of a big clean-up scarcely provokes comment, and people have come to regard enormous returns from that mine as a matter of course. The crushing of 85 tons of Champion ore, just completed, yielded in the neighborhood of \$9,000—an average of over \$100 per ton. And that is not in excess of former returns from the same quantity of rock, not to mention the fact that the mine has been making for years. We have frequently charged the State to "bait" our "Champion," but West Point still carries the lead for having the richest quartz ledge in the country.

GRAVEL MINING.—While a tour of the gravel mines in this vicinity does not develop much that is new, it is convincing of the fact that work is being energetically conducted, the miners making good use of the water at present running in the ditch in anticipation of an early failure of that supply.

At the Duryea the battery is kept in constant motion day and night. A large force of hands are now employed in running tunnels and "breasting out" gravel. The Duryea is remunerative to its owner.

BROWN & CO.'S NEW TUNNEL ON TUNNEL RIDGE is fast approaching the channel, only 75 feet more being necessary to complete the work. We have an idea that when the channel is reached Brown & Co.'s tunnel claim will prove to be one of the best paying ones in this section of the country.

VEITH, proprietor of the Excelsior hydraulic on Tunnel ridge, is just "scooping" out the gravel by his powder and water process, and he makes it pay. Mr. Veith employs 20 men in and about his claim.

MORSE'S hydraulic, on Tunnel ridge, is in full blast. His claim is now in excellent condition for working to advantage, and ranks among the best paying in this vicinity.

COOK & CO.'S mammoth hydraulic, near the French hospital is progressing favorably. He uses 300 inches of water, has a pressure of 200 feet and a flume over 100 boxes long. Cook expects to clean up shortly.

HARRISON, the well known Happy Valley "squirrel" is working away with his usual energy and vigor. His mine is in good working condition, and its proprietor is satisfied with the returns.

UPPER COUNTRY JORS.—A company from S. F. are now engaged in working the Tolland & Miller lead with good results. Needhardt & Johnson, owners of a very promising lead situated near the Lone Star mine, have out about 30 tons of rock. Good judges say that the rock will average \$80 per ton. Porteous & Co. have recently struck very rich rock in their mine at Bannerville. Williams & Co., owners of a promising lead a few miles from West Point, have lately struck good rock and plenty of it. The ledge is a wide one. Rock from the Granite lead is being hauled to the Josephine mill and crushed. Work on the Mina Rica is progressing favorably. Sundermyer & Co., at Independence, have out 200 tons of quartz on the Tunnel ridge. In their 100 feet from the main shaft, they have struck rock that will average over \$100 per ton. Sundermyer & Co. have one of the best mines in the upper country district. Clark and Harris's mills are running in full blast on custom rock. The mining interests generally in the upper country district are improving.

EL DORADO.

THE MINES.—El Dorado Republican, May 3: At Logtown, Mr. Harding is now running the mill on surface rock, which has paid an average of \$20 per ton, and many hundred tons in sight. The Condo company are quietly taking out splendid ore at their claim. Williams & Co. are mining out a fine lot of rich quartz from the old Wilder lead. Their size will pay about \$80 to the ton. Messrs. Galt & Lovless have good prospects at Honeycomb; indeed, the whole country is full of prospectors, and nearly all are satisfied with their mines. I yesterday visited a new shaft being sunk by Gray & Warf. They have discovered a fine body of porphyry, encased in slate, all of which contains gold. They have hopes of soon reaching a rich vein. They also find indications of this mine having been worked in ages gone by.

THE PACIFIC.—This formerly famous mine will soon be

in full blast again. We visited it on Tuesday, and found a force at work, under charge of Dan Wickham, putting the machinery in order, and by the last of the week the hoisting works will be ready to start. It is thought that two or three days will be sufficient to free the mine of water, and then sinking will be commenced, and at the same time a large body of low-grade ore to the south of the 300-ft level will be taken out. This is the lowest level yet reached. By sinking another 100 feet, it is believed that the same vein, which paid so well from the 300-ft level, will be developed.

THE WARREN BROS. of Oakland, who have the management of the Old Hickory and the river claim above the Bar bridge, have completed an easy wagon grade to the former mine from the old Chile Bar and Kelsey grade, and are now engaged in grading a road to the river claim. Work will soon be commenced and vigorously prosecuted upon the latter claim. Upon the former, it is not their intention to rush things before next fall.

INYO.

SANTA RITA.—Coso Mining News, May 5: The Santa Rita furnace, which was started on the morning of the 26th ult., has been running constantly every day since, with the exception of three or four hours, when it had to stop for some slight repairs. The number of bars of bullion turned out is very creditable indeed, and regular shipments are being made.

MOBAC.—We hear that the connection by shaft has been made between Confidence No. 3 and No. 4. It is said the mine looks better than ever, and the facilities for working will now enable the company to supply the furnaces at a greatly reduced cost.

NAPA.

SILVER.—Callista Cor. Lake County Bee, May 3: Our silver mines are being rapidly developed and promise rich results. I paid a visit to a few of the mines since the Palisade and others in the neighborhood, and found them looking well. The Palisade is about two and a half miles north of Callista. Upon my arrival there I found Mr. Bivins with a force of men (white) busy at work sinking a shaft, intending to tap the ledge at about 50 feet from the surface. I found the ledge well developed, being about 11 feet wide. The rock on the outcroppings along the ledge as well as the developments warrant it. Adjoining this is the Stillwagon claim. This company has a force of men employed. The Centennial is another well defined ledge. Men will be put on here next week. I understand that the Callista company will start up their mill and mine soon.

QUICKSILVER.—The quicksilver mines are doing well. The Great Western and Oak Hill are shipping their regular amount of quicksilver weekly. The Mason will soon have their new furnace ready, and will then start up; they have a large amount of high grade ore on their dumps. Capt. Wright, of the American, is not certain whether that mine will start up this season or not.

NEVADA.

REPUBLIC.—Nevada Transcript, May 2: This mine, located near Eureka, of this county, has recently been purchased by some early settlers and farmers of this State, and preparations are being made to erect a 20-stamp mill. The vein is very wide and is free milling ore, there being but little or no sulphurets in the quartz. The ore will mill from \$7 to \$10 per ton, and the conveniences for mining and milling could not be better improved. It is estimated that the cost will not be more than \$3.50 to mill and mine the ore. We look upon this as one of the most substantial and steady mines in the county, and believe the enterprise has a good future before it. The Republic is located in the great quartz belt which runs parallel to the Sierra Nevada mountains, and extends through Nevada, Sierra and Plumas counties. It is in this great belt that the Sierra Butte mine is located, which has been worked for the past 20 years, and has disbursed monthly dividends regularly for 18 consecutive years. The Sierra Butte has an 80-stamp mill run by water power, and is the largest and best equipped of the Republic.

THE WATT DRIFT M. Co., located on the blue gravel channel, near North Bloomfield and Moore's Flat, have recently purchased a 60-horse power engine for pumping and hoisting. This company has the heaviest machinery in use of this class of mining in the State. They are down with their main shaft some 60 feet.

JACOB & SARGENT are making preparations to sink a shaft into the great quartz belt which runs parallel to the Sierra Nevada mountains, and extends through Nevada, Sierra and Plumas counties. It is in this great belt that the Sierra Butte mine is located, which has been worked for the past 20 years, and has disbursed monthly dividends regularly for 18 consecutive years. The Sierra Butte has an 80-stamp mill run by water power, and is the largest and best equipped of the Republic.

The Sierra Butte has an 80-stamp mill run by water power, and is the largest and best equipped of the Republic.

GOOD GRAVEL.—Foothill Tidings, May 5: In the Washington mine, which was located for a quartz ledge at first, a bed of gravel was struck some time since and recently a drift has been run off upon it which brings to light a lead of regular blue gravel, and the prospect is good for paying gravel mine as of a good quartz vein. Quite a quantity of this gravel was taken out this week and washed, and the clean-up gave a return in coarse gold of fully 50 cents to the wheelbarrow load. We understand that arrangements will soon be made for working this deposit, which has been located for the Washington company.

A GOOD MINE.—The Idaho mine of this place will pay its 33d dividend on Monday next, aggregating in the eight years it has been running the neat little sum of \$2,148,820 as clear profit to the stockholders. As much more has been paid out from the product of the mine to workmen, merchants, etc. The Idaho is one of the best mines in the State and bids fair to continue such for many years to come. The chances for opening up others as good are not yet taken. Keep prospecting!

GRAND MINES.—Nevada Transcript, May 5: John McAllis, Superintendent, and one of the owners of the old Camer and Goodspeed claims, in Little River township, was in town yesterday. Since they bought the property, they have built two reservoirs, and otherwise expended in all about \$10,000 in putting the claim in good shape. They will commence washing some time next week, and will use 1,200 inches of water.

GRAND MINES.—This mine is still doing well in the way of taking out good quartz. A crushing of 60 loads has just been cleaned up, and the yield was \$3,300 in free gold, not counting in the sulphurets saved.

COLD SPRING.—Nevada Weekly Gazette, May 5: The Cold Spring gravel mine is located on the south side of the Washington road, about three miles from town. They have run 3,600 feet of drifts and tunnels, mostly through regular blue gravel, and the prospect is good for paying gravel mine as of a good quartz vein. Quite a quantity of this gravel was taken out this week and washed, and the clean-up gave a return in coarse gold of fully 50 cents to the wheelbarrow load. We understand that arrangements will soon be made for working this deposit, which has been located for the Washington company.

PLACER.

WORKING.—Dutch Flat Forum, May 5: The warm weather of the past week has not been favorable for our water ditches, as the effect of such weather is to shorten the season. The various mines in this section are working vigorously, so as to reap all the benefit possible while the water lasts.

THE POLAR STAR and Southern Cross continue washing at intervals, with one head of water, alternating from one claim to the other, as circumstances require. The Elmore Hill and Franklin are washing as continuously as possible.

THE BAKER and Star & Union claims both made a partial clean-up on Monday, changing their blocks so as to have them in good order for a long and profitable run. Neither of these claims were unable to wash any bottom gravel, and the rich deposit in both claims still lies ready for the approaching run. The blast in the Baker looked up a large area of bottom gravel, but only a small portion even of the top was washed off. These claims are now in first-class trim, and it is believed the next clean-up will be big. It is to be lamented that these claims were not ready by the commencement of the season, as the amount of gold that has been taken out heretofore.

THE FRANKLIN is improving the time washing away the gravel loosened by the last blast, and are preparing for driving another powder derrick. The derrick works to a charm, and the large boulders are being disposed of advantageously. The Pacific is washing day and night and promises well.

HUGH TREASURE.—Placer Herald, May 5: The water supply this season being short, the extent of the gold yield this year must depend more than usual on the quartz and drift mines. While the yield of the former will reach at least a full average in Placer county, the latter promises to exceed the average sufficient to make up very largely for the deficit in the yield of hydraulic claims. Besides the more general attention that is being given to drift and cement claims, heretofore worked, some new ones of this character have within the last year been opened. Notably among them is the Hidden Treasure, located on the Damascus lead, about four and a half miles from Damascus, and about six miles from Michigan Bluff. This claim was discovered by some of the original owners of the Mountain Gate, a noted drift claim near Damascus, who, by taking careful observations of the course of the Mountain Gate lead, were able to come upon this treasure some four miles away, on the opposite side of a rugged divide, by running a tunnel about 600 feet. The gravel was soon found to be very rich, and a company was at once formed for working it. This mine has yielded steadily since its first discovery, though up to the present, much of its proceeds, we understand, have been expended in getting the mine in shape. The mine is divided into 36 shares, held at about \$7,000 each, and not particularly for sale at that. At present the company is able to work but 40 men, and the yield is about \$12 a day to the man. As the breast is widened, they expect to increase their force, and every indication points to an extensive yield this coming summer.

PLUMAS.

QUARTZ PROSPECTUS.—Plumas National, May 5: From several gentlemen who have been in the Greenview country during the past week, we learn that the quartz fever is still raging, and developments are being made almost daily, which show that the mountains in that section are full of valuable lodes. Plumas certainly promises to be the Banner mining county in the State ere many years.

SANTA CLARA.

QUICKSILVER.—San Jose Mercury, May 5: For some time past we have heard rumors that valuable and extensive developments of metal have been made on the lower levels of the Guadalupe mine. We do not usually give credence to reports of this character, but in this case, from careful inquiry, we understand them to be well founded, and they require some significance from the fact that three members of the great bonanza firm of San Francisco have recently made several visits to the Guadalupe, and since then the product of that mine has been regularly shipped from our depot, consigned to Colonel Fair, the bonanza mine Superintendent, at Virginia City. We have it from reliable authority that the product of the Guadalupe mine is increased to at least 2,000 flasks a month, or as much more as the market will take, all of which we heartily rejoice at for the sake of our laboring population, who, in consequence of the continued drought and failure of crops, will welcome the new field of labor that so unexpectedly opens for them.

TRINITY.

FINISHED.—Trinity Journal, May 5: Mr. G. W. Sleeper informs us that the mining season is at an end in Hay Fork, that himself and partner quit piling last week. This season has been a terrible short one everywhere.

QUARTZ FOUND.—We learn that a quartz ledge has been found back of Perkins' bar, above the Arkansas dam, and arrangements are being made to prospect it. We not advised as to the prospects obtained from the quartz. The ledge is found in the presence of free gold in considerable quantities.

TULARE.

PLACERS.—Visalia Delta, May 5: Several parties from the Mill creek placer mines were in town last week, and had in their possession some fine specimens of washed gold. One piece weighed \$14, another \$38, an others less. We have been informed that Mr. McLean has staked out a claim five miles from the original diggings, on a flat, from which he had taken out an average of \$40 per day for six days. Mr. Neil owns a claim just below the one of Mr. McLean, which prospects equally well. There is not a superabundance of water, but enough for quiet working purposes, with a prospect for more as the weather increases in warmth. The gold sells in Visalia at \$17.40 per ounce.

YOLO.

THE CAL. Q. M. Co.—Yolo Mail, May 3: The news from the California quicksilver mine is that a sudden change has taken place for the better. One year ago there was but little silver being produced, the mines were apparently giving out; rich ore was not in sight, and everything seemed to be discouraging. Now, however, the new management, the mines are being developed; rich ore is found in abundance; the furnaces are constantly reducing ore, and between 70 and 100 flasks of quicksilver per month are being produced. There are about 150 laborers at work, and everything is lively.

YREKA.

GRAVEL IN THE STREETS.—Yreka Union, May 5: Some of the gravel from the bottom of the excavation for the new cistern at the corner of Miner and Oregon streets, prospected several "colors" to the pan. All the gravel bed under our town would doubtless pay well if mined, still we would not advise our citizens to tear down their buildings for the purpose of mining gravel lots.

QUARTZ PROSPECTING.—Messrs. McConnell and McManus, R. O. Dewitt and others of the Norfolk quartz company are about to send East for a portable quartz mill, which it is claimed will do the work of the usual four stamp mill, but is a great deal cheaper. They will use it to thoroughly prospect the quartz they have taken from the Norfolk and Lodi claims, and also of other claims in which they are interested. We are informed that a subscription is being taken up at Cottonwood to purchase one also, to test the many ledges around there. If these mills can do what is claimed for them, their introduction here will be of incalculable benefit to this county.

Nevada.

WASHOE DISTRICT.

YELLOW JACKET.—Gold Hill News, May 9: The station at the bottom of the north winze below the 2040-ft level is opened, and the drift east started for the commencement of explorations at the 2200-ft level. As soon as the drift is well opened another will be started south from the same

station, thus exploring the ledge in both directions. The material is birds-eye porphyry, with small streaks of quartz, some of which carry a little ore. In fact the whole of the ledge matter at this point bears a lively, very encouraging character, justifying the opinion that a good ore body might be found in that vicinity, the more especially as very good ore streaks were found directly above in the 2040-ft level.

CON. VIRGINIA.—Daily yield, 400 tons of ore, keeping the mills all running at their full capacity. The ore stops on the 1050-ft level continue rich. The face of the south drift on the same level, advancing to connect with the deep winze, also continues in the finest character of ore. The upraise from the 1500-ft level has reached and connected with the openings of the 1400-ft level. This winze, in ascending, cut through a considerable vein of very rich ore lying west of and entirely separated from the main body by a division of barren ledge material. This ore has a curved course to the north and west, directly away from that of the main vein, which is to the north and east. In accordance with our former reports, the old dividend of \$2 per share, aggregating \$1,080,000, was declared on the 7th inst., payable on the 15th.

DAVENPORT.—Daily yield of 500 tons of ore. The ore stops are showing splendidly at every point, and continue their regular yield of rich ore. At the same time the mine put on a more favorable appearance than at this time. Day before yesterday the regular monthly dividend of \$2 per share, aggregating \$1,080,000, was declared. The mills are all kept running up to their full crushing capacities. The 1750-ft station in the C. & C. was commenced yesterday.

OVERMAN.—The east drift on the 1400-ft level on Monday last encountered a strongly increased flow of water, so strong, in fact, as to force a suspension of the work for 36 hours. Last evening, however, the flow was again greatly lessened and work was resumed in the face. The formation in the face of the drift denotes a near approach to the vein, quartz beginning to show quite freely.

OPPIN.—Sinking the main incline is making the best of progress. The road to the depth of 100 feet yesterday, and to-day preparations are being made to put in the station set, preparatory to starting a drift at that point to cut and prospect the ledge. It will be necessary, after completing the station, to continue the shaft to a sufficient depth to form a pump before it will be safe to cut the vein. The Winfield mill is kept steadily running on the reserve of ore accumulated in the dumps.

SILVER SPRING.—Sinking the shaft is being pushed steadily and vigorously forward, the bottom in favorable ground, carrying streaks and stringers of quartz of a very fine character. The shaft has three compartments. **CHOLLAR-PODSI.**—Daily yield, 100 tons of ore, taken from the old stops above the level of the old Podosi tunnel, and assays on an average about \$20 per ton.

SILVER HILL.—Sinking the main incline and operations at the shaft level have been temporarily suspended. The north drift on the 650-ft level is going steadily forward, the face still in quartz and ledge matter of the most favorable description.

SUTRO TUNNEL.—During the past week the material in the face of the header has been very hard, being composed of very close-grained species of porphyry, with streaks of quartz and clay, the whole working and blasting very disadvantageously. The rock is, however, becoming more even in character, as well as softer, working to much better advantage. Total length of tunnel last evening, 16,713 feet.

NORTH CON. VIRGINIA.—The new station at the 1300-ft level is completed, and a drift started to cut the ore vein at that point. Sinking the main shaft has been temporarily suspended, pending the opening of the station and starting the drift at the 1300-ft level.

PULLMAN.—The east drift on the 1600-ft level is steadily advancing, with favorable prospects of soon reaching the ore vein.

BELCHER.—Daily yield, 80 tons of ore. The prospecting drifts on the 1600-ft level to the southward show no new changes. The flow of water is still quite strong. Sinking the combination drain shaft is making the best of progress.

MEXICAN.—The quartz and ore in the upraise from the 1465-ft level continues of a very fine and encouraging description. Good headway is being made with the raise, the entire size of which is in quartz. The east cross-cut from the north drift on the 1700-ft level has penetrated some very fine quartz.

JUSTICE.—Daily yield, 400 tons of ore. The ore stops on the 600, 700 and 800-ft levels are all yielding finely and promise well for months to come. The winze below the 800-ft level is still in ore, and a good quartz vein. The south drift on the 1000-ft level continues in good ore. This level is opening up splendidly.

GOULD & CURRY.—The main south drift on the 1700-ft level, running to connect with the Savage deep winze, is being pressed ahead at the usual fair rate of speed, the face in soft, favorable ledge material.

CALDONIA.—Sinking the shaft is making excellent progress. Much of the quartz is of a very fine character, some of it being highly impregnated with sulphurets of iron, giving low assays of both silver and gold.

IMPERIAL CON.—Sinking the south winze near the Yellow Jacket line, below the 2135-foot level, has just been commenced.

SAVAGE.—The water is being gradually reduced and is now much more easily held in check than at any time since the mine was flooded. A steady run of one hour day before yesterday, in conjunction with the pumps of the Hale & Norcross, resulted in lowering the water nine feet.

HALE & NORCROSS.—The repairs to the cave in the main incline is making all the headway possible, considering the great heat and the fearful difficulties under which the work is prosecuted.

THE BRIDGE.—The three cross-cuts now being run on the 1700-ft level are each being steadily advanced at a favorable rate.

LADY WASHINGTON.—The face of the north drift on the 850-ft level is still in a fine character of quartz and ledge material.

PROSPECT.—Face of main west drift, at the 400-ft level, continues advancing in very hard working material.

NEVADA.—Prospecting the 1750-ft level, both north and south, from the main shaft is making the best of progress. The chances for yet developing some good ore on that level is first-class.

DAYTON.—Some excellent ore has been opened up in the east drift on the 220-ft level, ore that will, no doubt, assay a good milling profit.

ALTA.—Sinking the shaft has been resumed. The new pump is working splendidly, and will lift the water for a depth of 200 feet.

NEW YORK.—The operations on the pumping compartment are all that is being done in the mine at present. **LEVATHIAN.**—The faces of both drifts are in very encouraging vein matter, with an occasional streak of low-grade ore.

JULIA.—The face of the south drift on the 1800-ft level is showing fine quartz and ore, that assays from \$20 to \$25 per ton.

BALTIMORE CON.—The northeast drift on the 1400-ft level is being pushed vigorously forward, the face in a fine character of vein matter.

UNION CON.—The north drift on the 1300-ft level is showing more quartz in the face.

ATLANTIC CON.—The shipment of ore to the Boston mill has been commenced, and crushing will begin to-morrow morning.

EUREKA DISTRICT.

HAMBURG.—Eureka Sentinel, May 3: The Hamburg company is daily receiving large quantities of charcoal at their furnace. It is particularly lively up around the coal shed, above their works.

The Richmond company are running but one furnace at their works, they having shut one down last Saturday. They have about completed the repairs on some of them, but no time is set for starting them up.

Snow is rapidly disappearing from the mountain peaks that encircle Eureka.

THE ENGINEER.

Interesting Experiments with Hydraulic Cements.

In the course of a long essay on cements, a writer in the *Polytechnic Review* states that the most thorough and valuable contribution to our knowledge of the influence of foreign addition upon the properties of the hydraulic cements, the technologist owes to the industry of Mr. Frederick Schott, the results of whose experiments with Portland cement are so highly important and suggestive that they deserve the careful study of all who are interested in the subject.

Mr. Schott asserts that the hydraulic properties of the cements are by no means conditioned by the purity of their composition, but that, on the contrary, they may suffer very considerable modifications from this standard without destroying their hydraulicity; indeed, this property may even be decidedly exalted by such modifications. In substantiation of these statements the author details the following experiments: A sample of Portland cement, mixed with moderately diluted hydrochloric (muriatic) acid, solidified quite rapidly, and, after immersion in water for nine days, it had attained a stony hardness, and was externally quite smooth. If the muriatic acid used for the mixture is concentrated instead of diluted, the sample solidifies even while being stirred, and cannot be poured from the vessel. With tartaric acid the result is the same, solidification occurring instantly. This phenomenon may be best observed by first mixing the cement with water to a stiff paste, and thereupon moistening the mass with the acid solution, when it hardens at once to stony consistency. A sample treated in the manner here described could scarcely be scratched with a knife after having been immersed for six weeks in water. Still more remarkable, however, is the action of the carbonate of soda (the soda of commerce). Portland cement, mixed to a thin paste with a cold saturated solution of soda, solidifies so rapidly that it may, with difficulty, be poured from the vessel. Carbonate of potassa behaves in this respect precisely like soda. When the oily liquid which is formed by treating this salt with a small quantity of water, is mixed with cement so as to form a thick syrup, it rapidly solidifies, and, when immersed thereupon in water, it rapidly acquires a very considerable hardness, without exhibiting the slightest disposition either to disintegrate or to scale. A sample prepared as just described, after immersion for 14 days, was found, upon drying, to be so hard as almost to resist scratching with the knife; it gave back a clear ring when struck with the hammer, and when written upon with ink, gave back the characters plain and sharp, without the slightest spreading.

A solution of silicate of soda or potassa (water, or soluble glass) very materially adds to the hardness and density of the cements. A cement casting, if immersed, after having sufficiently hardened to be removed, in a very dilute solution of the silicate, solidifies thoroughly; it is necessary, however, to renew the solution from time to time, until, after long contact with the cement, it gives a constant precipitate with chloride of ammonium. Very hard blocks are likewise produced by mixing the cement directly with dilute silicate solution, the samples solidifying more rapidly. A syrup-thick silicate solution, thinned with an equal volume of water, and then mixed with double its weight of cement, gave excellent results. Portland cement, stirred into a syrupy solution of silicate, solidifies at once. Blocks of extreme hardness were obtained by taking samples of cement which had acquired some hardness in water, allowing them to dry somewhat, though not entirely, and dropping thick silicate upon their surfaces until no more was absorbed.

Portland cement, treated with a cold saturated solution of chloride of ammonium (sal ammoniac), cemented very well, and in a few days had acquired, in the air, a very considerable degree of hardness; after immersion for a week in water, the sample had become so indurate as to emit a sharp sound when scratched with the knife.

Carbonate of ammonia exercises a very favorable action upon the cements, hastening the hardening process and augmenting the density of the product. Samples laid in the solution of this salt acquire extreme hardness in a very short time.

USE OF STEEL IN RAILWAY STRUCTURES.—The committee, consisting of Sir John Hawkshaw, Colonel Yolland and Mr. Barlow, appointed by the Board of Trade to consider the practicability of assigning a safe coefficient for the use of steel in railway structures, and the correspondence connected therewith, have made their report. *Iron* says: They recommend that the employment of steel in engineering structures should be authorized by the Board of Trade under the following conditions, namely: 1. That the steel employed should be cast steel, or steel made by some process of fusion, subsequently rolled or hammered, and that it should be of a quality possessing of considerable toughness and ductility, and that a certificate to the effect that the steel is of this description and quality should be forwarded to

the Board of Trade by the engineer responsible for the structure. 2. That the greatest load which can be brought upon the bridge or structure, added to the weight of the superstructure, should not produce a greater strain in any part than six and a half tons per square inch. They remark that cases may arise when it will be proposed to use steel of special make and tenacity, and when a higher coefficient than the above might be permissible, but they think those cases should be left for consideration by the Board of Trade when they arise.

Utilizing Niagara.

Two weeks ago we printed a paragraph from an English engineer proposing to use our great cataract. It now appears that the Canadians have tackled the proposition at once. The *Ottawa (Canada) Press* says:

A letter has recently been addressed to His Excellency the Governor-General, by Horace H. Day, a gentleman who owns the American side of Niagara falls, on which side the water-power much exceeds that of the Canadian fall. Mr. Day recommends the utilization of this vast water-power by the establishment there of manufacturing for spinning and weaving cotton cloth. When our ship canals, and eventually the Pacific railway are completed, the subject of cheap production may have a measure of interest to our manufacturers now not even thought of. The chief points of Mr. Day's scheme are the following, and should his ideas as yet fail to be appreciated, we may recall to mind George Stephenson, fighting his railway enterprise through amid the ridicule of Parliament and people, and Mr. Muntz going humbly from one ship-owner of London to another vainly asking permission to apply, at his own expense, a coat of his metal to the bottoms of their ships:

1. The formation of compressed air, by means of the water-power, and its appliances to drive the machinery of cotton factories, placed where convenient, the air being conveyed in pipes and applied to the common steam engine.

2. The manufacture, by this means, of cotton cloth, so near to the producing points of the raw cotton and of the food staples, as materially to lessen the cost of production.

3. The loading and unloading of vessels by means of the same cheap hydraulic power, the only expense of which is, of course, the erection of the apparatus.

4. The gray cotton cloth being so manufactured, its transportation (when the canals are enlarged), in sea-going vessels, direct from the point of production to England, there to undergo the finishing processes of bleaching and printing, and to be thence distributed to the markets of the world.

We understand that His Excellency has promised Mr. Day to lay his communication before the Dominion government, and to forward a copy of it to the Secretary of State for the Colonies, for the consideration of her Majesty's government.

Official Report on the Eads Jetties.

The sixth report of General Comstock, the Government engineer charged with the inspection of the progress of the works for the improvement of the South pass of the Mississippi river under J. B. Eads, was received at the War Department April 9th. The report is quite long. It is accompanied by maps and diagrams fully illustrating the work. It will be sent to the public printer for publication at once. The following extracts are of interest:

"At the mouth of the South pass, between November 18th, 1876, and March 16th, 1877, a few new wing-dams have been built and some old ones repaired. About 16,000 cubic yards of material have been dredged out at points where the channel was worst. A storm of December 30th, 1876, damaged the ends of the jetties and the wing-dams near them quite severely; 26,000 feet of the west jetty has been raised by mattresses two or three feet thick built in place; a layer of stone eight-tenths of a foot thick on this portion gives it a height varying from five-tenths of a foot to two feet above average flood tide. The other end of this part is 700 feet from the sea end of the jetty; 167 new piles have been driven in the jetty. Little work has been done on the east jetty. The channel of 20 feet in depth at the mouth of the South pass which, on December 27th, 1876, had a width of 200 feet from the pass of the Gulf, has narrowed at a point near the sea end of the jetties so as to be but 70 feet in width, and at a point a little below the head of the west jetty so as to be 180 feet in width.

"A table accompanying the report shows that depth could be taken through between the jetties as follows:

"June, 1875, 9 2-10 feet; May, 1876, 15 feet; August, 1876, 19 8-10 feet; November, 1876, 20 3-10 feet; March, 1877, 20 5-10 feet. A comparison of the soundings off the ends of the jetties with those of June 21, 1876, shows that in that period the 50, 70 and 100 feet curves have on the whole remained in the same position. At the head of the passes the west T-head has been extended up-stream to meet the line of mattresses across the head of the Southwest pass, and its upper part has been made a solid dyke. A line of mattresses has been carried from the east T-head down to the head of Goat island. A solid mattress dam has been built across the old east entrance to South pass. About 50,000

cubic yards of dredging has been done, making the total amount of dredging here 40,000 or 50,000 cubic yards. The river began to rise on January 24th, and caused a sharp scour between the T-heads, so that 23 feet 9 inches could be taken from the Mississippi river into the South pass on March 7th, 1877."

THE SIMPLON TUNNEL.—The *English Mechanic* says that the preliminary studies for boring the great tunnel of the Simplon and making accessions lines are now in course of execution. The plans and measurements have been completed in the offices at Lausanne. The line commences at Brigue, which will thus become the international station, to enter the tunnel, which will have a length of 18,340 meters. The end of the tunnel will be near d'Isella, and the line proceeds from there to Bombo d'Assolla. The total length of the line will be 46,900 meters. Near Bombo it will rejoin the old works, the Italian continuing to the station of Arona. As far as the village of Crevola the line follows the left bank of the Boveria, but crosses it there on a large viaduct.

The Pelican Mill.

A long time ago, says the *Colorado Miner*, when Georgetown was a gold mining camp and before silver was discovered in the district, Providence, R. I., sent out a man with a pile of money to build a quartz mill here. A large sum of money was paid for a number of supposed gold lodes. A valuable mill site and water-power were secured and an expensive quartz mill erected. The mill site covered the ground upon which Georgetown is now built. The investment for years appeared to be a total loss, but the discovery of silver, and consequent influx of population, enabled the What Cheer company to dispose of their property advantageously.

The first silver brick made in Colorado came from this mill. Garrett, Martine & Co. put in the Bruckner cylinder, (an invention of Prof. Bruckner, and first practically tested here,) which, in spite of the bitterest opposition, has proved to be a good machine and is still regularly and successfully grinding away.

Garrett, Martine & Co. were succeeded by Hupedon & Walters, and the concern was popularly known as the "German Reduction Works," for some time. The firm of Palmer & Nichols followed, and finally the Pelican company purchased the property and, for a number of years, have run the mill on ore from their own mine. The mill was recently overhauled and enlarged, three new cylinders and more barrels for amalgamation were added, also a new 10-stamp mill, new dust-chamber built, two new boilers substituted for the old single one, and a new engine room built. It is now as complete a silver mill as there is in the State. The firm of Fraser, Chalmers & Co., Chicago, furnished a great portion of the new outfit.

To those not familiar with the process of silver production, it may be well enough to say briefly something about the *modus operandi*. The ore arrives from the mine in a common quartz wagon, and is first thoroughly dried, after which it is pulverized in the 10-stamp mill—a double-discharge California battery. The stamps weigh 650 pounds each, and drop 90 times per minute. The timber of which this quartz mill is constructed has a history of its own. It is of the best Wisconsin oak, was purchased by an Eastern company proposing to operate at Montezuma, Summit county, was transported to that inaccessible district at a heavy expense, and finally brought over the Snake river pass by the Pelican company, and placed in its present position. The money actually paid for these oak timbers would have been amply sufficient to pay for one of rosewood or mahogany. This by the way.

The ore, when pulverized, is carried to the top of the mill by means of an elevator, and deposited in a large hopper over each cylinder. This cylinder is made of boiler iron five feet in diameter and 12 feet long, and is lined with brick. Through the center there is a diaphragm so placed as to cause the charge of pulverized ore to be constantly moved from one end to the other. It is practically the same operation performed in the reverberatory furnace, but is done by machinery, and one man is able to roast and chloridize as much as 12 in the old way; besides this he has an easy position, the charging and discharging of the cylinders being the only real work there is about it. The cylinders are discharged into an iron car, and the ore is put on the cooling floor, after which it passes into the amalgamating barrels, from which the silver is obtained in the shape of amalgam, and the worthless ore is dumped into the creek. The time required for the operation depends on the character of the ore. Heavy zinc ore requires from 15 to 20 hours in the cylinder alone. The Pelican mill, with its five cylinders, has a capacity of 10 to 20 tons per day. The ore has been averaging about 100 ozs. per ton for some time past, just as it is broken and comes from the mine, without sorting. The silver produced is not as fine as it might be, ranging between 750 and 850, but this is a matter of economy. They are able to make it 999 fine, but the difference in price does not justify the extra trouble.

The Pelican mill is peculiarly interesting for several reasons. It produced the first silver brick from Colorado silver ore. It demonstrated the practicability of roasting ore by machinery and established all that the inventor ever claimed for the Bruckner cylinder. It is

the first mill in Colorado where dry crushing of ore was successfully tried.

The mill, under the prudent and economical management of Hon. B. F. Napheys, is producing a large amount of bullion annually, and is making a good profit on the labor performed. Mr. E. Y. Naylor, the Superintendent of the company, gracefully presides in the office, and Mr. Patrick is the assayer. This mill is one of the old landmarks, and has set good examples to other similar institutions now scattered all over the State.

Nevada County Mining.

We do not believe, says the *Nevada Transcript*, there is a better field for the energetic prospector than in this county, and time will prove that our mining ground up to this year has hardly been touched. In many localities there are claims upon which work was suspended when wages, water and other mining expenses were double what they are now, and which could be worked at a good profit. Many such claims could now be purchased at low rates, and could be fitted up at a small cost. There are also very large ranges along the gravel channels which are unprospected, and which have never been taken up, or even if taken up, they have been forfeited for not having complied with the requirements of the law. In these cases they are open for relocation, and in case of a contest, nine times out of ten, a suit would result in favor of the party who, in good faith, goes to work on the ground with the intention of uncovering the valuable deposits. The large number of locations made each month, as shown by the books at the County Recorder's office, proves that our mines are not being neglected by prospectors. There is one thing certain, and that is, it requires money to open these claims; but when the channel is reached by the prospector or locator, and the gravel is tested, if it pays, it is a very easy matter to obtain capital to carry on the development of the mine. In quartz, prospecting is being carried on quite lively, and scarcely a day passes by without a location is placed on record. During the past year many good claims have been opened, and though there have been a few failures, as there is in every business, the result has been most satisfactory. If a hundredth part of the money which has been lost by gambling in stocks on the Comstock had been invested in this county, we would to-day have more and better paying mines than there is in the State of Nevada. The great drawback to the development of our mines is, that capitalists have millions for speculation, but risk only a few hundred dollars for the actual development of mines. If these men can flood the market with certificates of mining shares without risking their own money to work the mines, they are ready to do so, and this practice has created the belief that mining is hazardous, whereas nearly all the losses are either from bad management, or because people have bought stocks which were never worth the paper they were printed on. But this latter kind of business has about petered, the people having got their eyes open to the fact that they have been continually robbed by stock manipulators, we already perceive the benefit that is accruing to this county. While we sympathize with the unfortunate victims who have lost heavily in stocks, yet their loss will be our gain, as it will redound to the prosperity of our own and other mining counties in this State, provided no more dupes can be found to invest their money in the Comstock manipulations. Stock gambling is carried on between brokers now, and when an outsider is silly enough to invest his money, there is a scramble for it, and his hard earnings are soon gone. The people now, more than ever before, seem to appreciate the situation. It is a sad lesson to some of them, but it may prove to be the best thing that ever happened, if not to them personally, to the community in which they live, and for the State. Something had to happen. A change was necessary to convince men that they were not all born to be rich, and that stock gambling was undermining the very foundation of the financial prosperity of the State. The last break in stocks did the business, and the mines of Nevada county will surely receive more attention than they have for many years past. We again reiterate, that as good a field for prospecting cannot be found on this coast, and Nevada county is the peer of the Pacific slope for profitable mining.

SALT WORKS.—A new enterprise has been started near the sink of the Humboldt, Nevada. The *Silver State* says that Walter Schmidt, the discoverer of the Rye Patch mine, has commenced the manufacture of salt near Brown's station on the railroad, and in a short time will be prepared to fill orders for the article in large or small quantities. The works are situated near the road, which enables the owners to defy competition. A sample of the salt was exhibited at the fair last fall, and was awarded a diploma by the committee. There is plenty of salt in Nevada, the Humboldt salt marsh being practically inexhaustible, but hauling it to the railroad is so expensive that its owners cannot compete with that from works situated near the road.

A SALE in this city of 33 tons of ore from the Silver King mine, A. T., aggregated \$39,510, the highest lot bringing \$4,650 per ton, and the lowest \$1,230. The ore came by the Southern Pacific.

Mining Affairs at Cerro Gordo.

A correspondent of the *Coso Mining News* says: In one of my former letters, I promised to give you a description of the Belmont silver mines, and here is the fulfillment of my promise.

In former years, when Cerro Gordo was in its bloom, and when two rival companies were eager to bring the ores at a living price, quite extensive operations were carried on there, as men could then afford to work their claims to advantage, and the camp gave employment to some 40 to 50 men. Now, when there is only one company at work, and that company buying the ores at their own price, the place is almost deserted. Ores, no matter how rich, are bought for 50 cents per ounce, silver, delivered at the furnace, and ore assaying below 40 ounces silver cannot be sold. And not alone this, but ores which formerly assayed hundreds of ounces now assay ridiculously low, so that miners are not at all satisfied or convinced of the honesty of the concern.

The mines are situated on the east of the Cerro Gordo mountain, about three miles from the town, and facing Lee district. The ore is mostly copper-silver ore, though carrying sometimes considerable lead, and all of it contains from \$20 to \$30 gold per ton. Indeed, with the exception of a small portion of it, it is mainly milling ore. The principal mines are the Belmont, owned by Mr. Wm. Hunter; the Witte-Kind, patented and owned by Mr. John R. Hughes; the Buena Suerta, owned by Dr. H. W. Gould; the McDonough mine and the Nettie, Barbarossa and Gracewood, owned by Dr. Hehner and K. C. Johnson.

Of these the Belmont is the most extensively worked. A large, well-defined ledge, of from two to three feet high, and carrying all free-milling ore. As high as 20 to 25 men have been employed here formerly. Hundreds of feet have been run in tunnels, drifts and shafts, and Mr. Hunter sold, four summers ago, ores to the amount of \$63,000 alone, keeping two pack trains constantly employed. From this an idea may be gained of the immense quantities of silver taken out of the camp. The Witte-Kind, adjoining the Belmont, has also been very largely worked. The ledge here is somewhat smaller, but the ore is of a very high grade, assaying as high as 400 to 500 ounces per ton. As, however, the mine is patented, its present owner prefers the ore to remain in the mine rather than selling it at such ruinous rates to the Union Consolidated company. The Buena Suerta is also a very valuable property, the richest ore in the district. Its owner, Dr. H. W. Gould, is residing at the mine, but refuses also to sell any more ore to our monopolists. The mines of Dr. Hehner and Kit Johnson are leased to some Mexicans, and in all of them considerable ore is in sight. In the Gracewood they are now sinking a shaft. The ledge is very regular, averaging some 18 inches in width.

It is a wonder, indeed, that mines as valuable as those at Belmont, should have gone begging so long for the want of proper means of reduction. It is true enough that there is no water, but a very good road can be made, with but very little expense, to the lake, and ores can be hauled down for about \$7.50 per ton. Ten stamps could be kept constantly running, and we do not know of any better investment in regard to mining enterprise in the county. A year ago, Mr. S. Linkton came over from Darwin, looked at the mines, and taking along some sacks of ore from the Belmont mines, had it milled. The result was 62 ounces silver per ton. This was as poor ore as was ever taken out. He then bonded the Belmont, Witte-Kind and McDonough for \$20,000, but for some reason forfeited his bond.

We have had a visit from Mr. Belshaw, and, as a consequence, a reduction of wages at the furnace as well as the mine, of 50 cents per day. The cause alleged is that the mine has not paid during the last year. Probably, however, the real cause may be found in the fact, that owing to the dull times and the general scarcity of money, such a reduction could now be safely made, and will be an established fact when ore will be struck in the new shaft. The latter is being steadily pushed ahead, and it is currently reported, and on good authority, that a large body of ore has been struck in the cross-drift, but that it is hushed up on account of their tax suit. Some very fine galena has certainly been taken out already.

That the Union Consolidated company should really have the assurance of going to law about their taxes, and how employees of that company could have gone before the Board of Equalization and made oath that the property was not worth \$8,000, and at a time when upwards of \$20,000 had been already expended alone for machinery and work on the shafts, is a cause of wonder to everybody at all acquainted with the prodigious resources of that mine.

MCGARRAHAN CLAIM AGAIN.—The application of the New Idria company for patents for quicksilver mines has been referred by Secretary Schurz to Assistant Attorney-General Marble, law officer of the Interior Department, and an animated argumentative contest is now in progress before him, between ex-Senator Stewart and William Neely Thompson in behalf of the company, and Montgomery Blair and others representing McGarrahan. Meanwhile the apparently everlasting controversy as to the history and merits of the case has been revived in the Washington newspapers.

USEFUL INFORMATION.

The Movement of Storms.

Prof. William Ferrel, of Washington, has gained and deserves high reputation at home and abroad as a student of meteorology. His constant endeavor is to bring it, as a science should be brought, to the tests of facts and mathematics. The essay which he has just delivered before the National Academy of Sciences will add to that reputation. This essay on the "Progressive Motions of Storms," is intended to show that the movement of great storms across our continent, for instance, is determined by the currents of our atmosphere—its upper currents especially. He presented in tabular form the results of his theoretical determinations as to the speed of atmospheric currents for different heights. By these currents neither the ordinary surface winds nor the winds which form part of great storms or cyclones are referred to, but the great easterly current which is mainly above the surface and extends far above the clouds. This current is chiefly due to the difference of heat between the equatorial regions, and consequently is greater in winter when that difference is greatest, as compared with summer, when it is least. The theory assumes that this current is swifter with increased heights from the earth, but varies with different latitudes. The figures of the increment are:

Latitude.	Per Mile of Height from Surface.	
	Winter.	Summer.
70	7.5	5.8
60	10.1	5.6
50	10.9	5.1
40	12.1	4.9
30	14.7	4.3
20	15.0	2.4

The increment is to be added to easterly surface wind; but where, as in low latitudes, the surface wind (trade wind) is westerly, it should be subtracted. Thus for latitude 40 degrees the amount to be added to the prevailing easterly wind at the surface would be, for a height of five miles, in winter, 60 1/2 miles per hour. In this great easterly current it is conceived that storms, cyclones, and the like are carried along though their specific winds may be blowing on the surface in an apparently contrary direction. The theory is partly corroborated by the calculation of the Rev. Clement Ley, of England, that the maximum speed of cirrus clouds having an altitude of four miles, is 120 miles per hour.

A theoretical explanation was also given for the observed circumstances that while the storms north of 40 degrees latitude go easterly, those south of that line go 30 degrees north of east. But Prof. Ferrel's chief object was to show that the progress of a storm most largely depends upon the general movement of the atmosphere; a movement increasing with altitude, and greater in summer than in winter.

PURIFYING PARAFFINE.—We read in the London *Mining Journal* that with a view to realize in an expeditious and economical manner the separation of the oil and coloring matter from paraffine, and the separation from each other of the constituents of other fats or fatty matters, whose constituents have different melting points, Mr. F. G. Morton, of Deptford, proposes to place the cakes or pieces of paraffine or other fats or fatty compounds in shallow boxes or cases constructed with perforated sides, interposing a quantity of common soda or other alkali between the cakes or pieces of paraffine or fat or fatty compound. The boxes or cases may each be composed of a frame of wood forming four lateral parts or sides, say about one inch wide, and of two perforated sheets of zinc forming the two other and larger lateral parts or sides; one at least of the perforated sides must be made removable for the introduction of the material to be treated. The perforated boxes or cases are placed about two inches apart in a tank of water heated by steam or otherwise (but preferably by steam) to a temperature slightly below that which will melt the constituent having the higher melting point, and the temperature is then regulated to allow the heat to gradually extract the constituent or constituents which melt at lower temperatures, as for example in the case of paraffine, to gradually extract the oil and coloring matter. As this operation is repeated the paraffine is finished and filtered in the ordinary way. For some operations, perforated boxes or cases as herein described may be employed without the use of alkali. The perforated boxes or cases may be arranged horizontally or vertically, and may be fixed, or may have an oscillatory or rotatory motion, according to requirement.

UNIVERSAL HYDRAULIC MOTOR.—According to a Turin fortnightly, *Il Progresso*, a certain Gerolamo Cavanaugh, of Genoa, has been in Rome demonstrating to the Minister of Marine the reality of an important discovery which he claims to have made. Cavanaugh substitutes water-power for steam in all application, even for locomotives and marine engines. He asserts that he is able to use liquids for the production of powerful mechanical effects, his invention resting (1) upon the utilization of the pressure from the bottom to the surface of any liquid mass, enabling him, with the outlay of but a small additional force, to elevate that mass; and (2) upon his utilizing this mass as a heavy weight, the pressure of which is converted into a driving or other power. We confess that the statement has a vicious circle look with it, which we do not find reassuring.

Peculiar Colliery Explosion.

The Manchester *Guardian* has the following: On Wednesday, when the workmen were leaving their work at Troedyrhiw colliery, situated in the greater Rhondda valley, and at the entrance into the Ferndale valley, the scene of a terrible explosion some years ago, a roar of rushing water was heard. Many men succeeded in making their escape to the surface, but it was soon discovered that 14 men and boys were missing. There were plenty of brave volunteers forthcoming, and many descended the shaft, which is 92 yards deep, and entered the workings. They quickly discovered that all the workings within a few hundred yards of the bottom of the shaft were filled with water to the roof, and no hope was entertained that anyone would be discovered alive. While the explorers were consulting what should be done, faint knockings were heard on the other side of the coal, at a distance, it was conjectured, of a dozen yards. No sooner was this heard than a score of men threw off their jackets, and, with mandrills, commenced cutting through the solid mass. The imprisoned did likewise. Relays of men worked with great energy throughout the night, and about four o'clock yesterday morning they reached within speaking distance of each other. The imprisoned men were greatly excited, saying that the rising water was gradually approaching them. It came out that there were five firemen and a boy. About six o'clock in the morning a mandril struck through. The next moment a terrible explosion, as that of a cannon, occurred, but not of gas, and one man was terribly cut about the face. A few minutes later, on approaching the hole made, it was discovered that a man named Morgan had been jammed in the hole, and that he was dead. The inundation had been so sudden as to imprison the air in the inner workings, and the force of this had kept back the water from the five men. The moment a small hole was made by Morgan's mandril this volume of imprisoned air escaped. Between eight and nine o'clock Morgan's dead body was brought to the surface. Yesterday afternoon Mr. Galloway and the officers of the Troedyrhiw and other collieries, after penetrating as far as possible into the colliery, heard knockings ahead of them. Some of the men left in the colliery, therefore, were still alive at the hour, but there is half a mile of water from the nearest point reached and where they are imprisoned, and, owing to a deep basin intervening, filled with water to the roof, it is feared that they cannot be reached for some days.

CONSOLIDATED TEA.—The operation of compressing or consolidating tea, as carried on by Messrs. Goundry, of London, is very simple. The tea is weighed out by girls—who almost exclusively carry out the process from beginning to end—into quarter pounds, which, one after another, are passed into molds on a revolving iron table, a piece of metal exactly fitting the mold being placed on the top. As the table revolves, each mold comes under the stroke of a hydraulic ram, which exercises a pressure of about 80 tons on each quarter of a pound of tea, reducing it to one-third of its bulk, and consolidating it into a mass, marked out by depressions into divisions of exactly half an ounce each in weight. As the table revolves, each cake is ejected from its mold, and the process, in which, by the way, not a particle of moisture is used, is completed. The effect of this enormous pressure is stated to be so thoroughly break the cells and smaller vesicles of the tea leaves that the theine and aromatic oil are set perfectly free, and the mass of tea is more easily affected by boiling water, in which it at once falls to pieces. The practical result is that the liquor produced from consolidated tea after ordinary infusion is considerably stronger than that produced from loose tea, varying according to the quality of the tea subjected to the process. It is found that a half ounce of consolidated tea gives in five minutes the same strength of liquor as the same weight of ordinary tea in four or five hours.

CALIFORNIA CONTRACT GOING TO ENGLAND.—The New York *Iron Age* says: If all the rumors we hear are true, the hoop iron contract is not the only large one that has been lost to us to give employment to English mills. We hear, from a reliable source, that a large order for plates for California, amounting to some 2,000 tons, has been or will be given to English bidders. The pig iron, bar and railroad iron trade of this country may be lost to England; but, as we have several times suggested, in the higher grades of iron the closing battle has not been fought yet. The "mother country" is getting down to "hard pan" as well as we, and when she gets there, and there is any improvement on this side of the water, there will be "blood upon the face of the moon."

DURABILITY OF PORTLAND CEMENT.—During the course of some recent experiments in Paris, it was found that a brick of pure Portland cement, which had been kept in water six weeks, broke under a tensile strain of 170 pounds to the square inch; but a brick, six months old, which had also been kept under the water, broke under a strain of 441 pounds per square inch. The experiments proved that cement hardens more rapidly when exposed to sunlight and fresh air than when affected by humidity, but that this is at the expense of the tenacity and impermeability of the product.

GOOD HEALTH.

The Doctor's Story.

Deacon Rogers, he came to me:
"Wife is agoin' to die," said he.
"Doctors great an' doctors small,
Haven't improved her any at all.
"Physic and blister, powders and pills,
And nothing sur: but the doctors' bills!
"Twenty women, with remedies now,
Bother my wife the whole day through.
"Sweet as honey, or bitter as gall—
Poor old woman, she takes 'em all.
"Sour or sweet, whatever they choose;
Poor old woman, she daren't refuse.
"So she pleases who'er may call,
An' death is suited the best of all.
"Physic and blister, powder an' pill—
Bound to conquer, and sure to kill!"

Mrs. Rogers lay in her bed,
Bandaged and blistered from foot to head.
Blistered and bandaged from head to toe,
Mrs. Rogers was very low.

Bottle and saucer, spoon and cup,
On the table stood bravely up,
Physic of high and low degree:
Calomel, catnip, boneset tea;
Everything a body could bear,
Excepting light and water and air.

I opened the blinds; the day was bright,
And God gave Mrs. Rogers some light.

I opened the window; the day was fair,
And God gave Mrs. Rogers some air.

Bottle and blisters, powders and pills,
Catnip, boneset, syrups and squills;

Drugs and medicines, high and low,
I threw them as far as I could throw.

"What are you doing?" my patient cried;
"Frightening death," I coolly replied.

"You are crazy!" a visitor said;
I flung a bottle at his head.

Deacon Rogers, he came to me;
"Wife is a-gettin' her health," said he.

"I really think she will worry through;
She scolds me just as she used to do.

"All the people have poohed an' slurred—
All the neighbors have had their word;

"'Twere better to perish, some of 'em say,
Than to be cured in such an irregular way."

"Your wife," said I, "had God's good care,
And His remedies, light and water and air.

"All of the doctors, beyond a doubt,
Couldn't have cured Mrs. Rogers without."

The deacon smiled and bowed his head;
"Then your bill is nothing," he said.

"God's be the glory, as you say!
God bless you, doctor! good-day! good-day!"

If ever I doctor that woman again,
I'll give her medicine made by men.
—Will M. Carleton.

Wearing Spectacles.

A writer in *Scribner's Monthly* for April gives an article on this subject, from which we condense the following. His views correspond with the generally received opinions of medical men with regard to this matter: It is currently believed that the use of glasses should be put off as long as possible; that a too early use of them is injurious, and that when once begun it becomes, earlier than it should be, a necessity. As the office of the glass is to supply the refracting power which the eye, through age, can no longer furnish, it is evident that so soon as a need of this artificial power is felt we should resort to it. By failing to do so, we deprive ourselves of much useful work of the organ, while the work it does is done under a disadvantage, and with greater or less risk. Far-sighted persons feel the need of assistance very early—often as early as the 25th or 30th year. When one can no longer read with ease the finest print of a newspaper at a distance of 12 inches, glasses are needed. Inconvenience will first be felt in the use of the eyes in the evening, and for a year or more their use may be confined to work at that time. Under ordinary circumstances the first glasses should be weak—say about No. 60, according to the numbering in this country. Such a number, however, should be selected as will enable one to read the finest print at a distance of 12 inches. A pair of spectacles of clear glass, free from defects, and accurately ground, which in a neat steel frame cost about \$3 or less, will do as much as pebbles, for which \$25 and even more is asked. For cleansing the lenses, use a piece of old, soft cotton cloth. The case in which glasses are kept should open at the side and not at the end. The rubbing of the lenses against the sides of the case soon mars their transparency.

BARE NECK AND ARMS.—An eminent physician declared: "I believe that during the twenty-six years I have followed my profession in this city, twenty thousand children have been carried to the cemeteries a sacrifice to the absurd custom of exposing their arms naked." And yet it is said the low-necked fashion is coming again. Do not follow it.

TURNIP SEED FOR INDIGESTION.—A reader of the *Press* writes as follows: I use turnip seed for medicine in case of dyspepsia or indigestion, and find them much better than the mustard seed, commonly used, besides they are much more palatable. They taste something like a nut kernel.

ADVERTISING RATES.	1 week	1 month	3 mos.	12 mos.
Per line.....	25	.80	\$ 2.00	\$ 5.00
Half inch (1 square).....	\$1.00	\$3.00	7.50	24.00
One inch.....	1.50	4.00	12.00	40.00

Four weeks are rated as one month.
Large advertisements at favorable rates. Special or
reading notices, legal advertisements, notices appearing
in extraordinary type or in particular parts of the paper
inserted at special rates.

SUBSCRIPTION IN ADVANCE.—Postage paid—one year, \$4;
six months, \$2.25; three months, \$1.25. Remittances by
registered letters or P. O. orders at our risk.

WRITE for the MINING AND SCIENTIFIC PRESS. We invite
not only professional men, but practical miners and
mechanics to contribute to our columns. All communica-
tions will be kindly treated. Authors, as well as readers,
will be benefited by corresponding.

ADDRESS all letters to the firm, and not to individua
members, or others, who may at any time be absent from
our office.

Our latest forms go to press on Thursday evening.

SAN FRANCISCO:
Saturday Morning, May 12, 1877.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Applications of Carlton's Axle
Set and Gauge; Lillie's Fruit Pitter, 289. The O'Hara
Chloridizing Furnace, 297.

GENERAL EDITORIALS.—An Improved Axle
Set and Gauge; A Fruit Pitting Machine; Milling, 289.
The Crown Point; Science and Practice; Salting the
Bullion; Foundry Notes; Hard Times on the Comstock,
296. Mechanical Ore Concentration and Separation—
No. 25; The O'Hara Champion Furnace; Amador
Mines; Items of Interest From the Mines, 297. Pat-
ents and Inventions; Notices of Recent Patents: The
Justice Mine; Confidence Gold Mine, 300. New Style
of Portable Engine; General News Items, 301.

MECHANICAL PROGRESS.—Balancing Buhrs;
Automatic Furnace Dampers; Rapid Steel Rail Rolling;
Petroleum for Priming of Boilers; Casting a Bronze;
Machine Drilling in Mines; Using Super-heated Steam;
Compressing Steel, 291.

SCIENTIFIC PROGRESS.—Chinese Buying Sci-
ence; The Depths of the Sea; Formation of Minerals;
Darwin's Conclusions on Plant Fertilization; A New
Era in Telegraphy; A Testimonial To Darwin; Evapora-
tion of Nitro-glycerine in Dynamite; Transit of Venus;
Distribution of Plants, 291.

MINING STOCK MARKET.—Sales at the San
Francisco, Pacific and California Stock Boards; Notices
of Assessments, Meetings and Dividends; Review of the
Stock Market for the Week, 292.

MINING SUMMARY from the various counties in
California, Nevada, Arizona, Idaho and Montana, 293-
300.

THE ENGINEER.—Interesting Experiments with
Hydraulic Cements; Use of Steel in Railway Structures;
Utilizing Niagara; Official Reports on the Eads Jetties;
The Simpson Tunnel, 294.

USEFUL INFORMATION.—The Movement of
Storms; Purifying Paraffine; Universal Hydraulic Motor;
Peculiar Colliery Explosion; Consolidated Tea; Califor-
nia Contract Going to England; Durability of Portland
Cement, 295.

GOOD HEALTH.—The Doctor's Story (Poetry); Bare
Neck and Arms; Wearing Spectacles; Turnip Seed for
Indigestion, 295.

MISCELLANEOUS.—Comstock Papers; Concentra-
tion in Montana; The Idaho Mine; San Diego Mines;
290. The Pelican Mill; Nevada County Mining; Salt
Works, 294. Mining Affairs at Cerro Gordo; McGee's
San Claim Again, 295. The Great Suspension Bridge
Between New York and Brooklyn; Experiments Made
by the Eastern Railroad Association; The Dives Mine;
Manufacture of Ammonia; Mines Sold; New Sulphuret
Works; Idaho Mines; A Lost Gold Mine Found, 298.

The Crown Point.

A meeting of the dissatisfied stockholders of
the Crown Point mine has been held to take ac-
tion with regard to the present management.
Mr. O. H. McKee read an elaborate report of
his investigation into the affairs of the company,
in which he made the following statements:

Since January 12th, 1875, eight assessments
have been levied, aggregating \$750,000. Dur-
ing 1876, 66,941 tons of ore were reduced, the
product being \$1,078,718. The total paid for
milling was \$667,199, leaving a balance to the
company of \$411,519. To this add \$500,000
drawn during that year in assessments, and the
total working expenses of the mine amounts to
\$911,519; and in addition to this the manage-
ment contracted an indebtedness of \$135,000,
making the total expenditure during 1876 of at
least \$1,046,519. In 1876 Yellow Jacket levied
assessments amounting to \$360,000; Bullion
(first since 1872), \$250,000; Overman, \$346,000;
Caledonia, \$260,000, and Imperial, \$350,000.
These companies did not mill any ore in 1876.
He thought the stock would become valueless if
the extravagant outlay was not checked.

After considerable discussion a committee of
three was appointed, composed of Messrs. Mc-
Kee, A. P. Wheeler and Kronberg, to investi-
gate the subject and report at a meeting to be
held shortly in a public hall. Among other
grievances, it was asserted that the present
Board of Trustees hold among the five only 175
shares of stock. All stockholders were urgently
requested to have their stock transferred to their
own names at least 10 days before June 4th,
as on that day there will be an election of new
officers.

Science and Practice.

The science of mining and metallurgy con-
sists simply in a knowledge of the results of
practice and experience; although many per-
sons seem to think that it is the other way, and
that practice is the result of the researches of
science. There is no reason at all why the sci-
entific man may not be practical as well, and
vice versa. The two go hand in hand. The
practical man may establish a fact and science
will preserve it for the use of others. The sci-
entific man may suggest an idea, but unless
proved correct by practice it is valueless and is
abandoned.

Most men seem to think that science means
Germany and books; that is to say, they think
it consists of knowledge gained in German
universities. What is taught there is simply
what has been learned by practice and expe-
rience, the scientific men having preserved the
facts and compiled them in a shape in which
they are accessible to all.

Now we are making science of this kind on
this coast every day, and the best kind of sci-
ence too. All we want is to collect and save it.
What is sometimes called "practice" is expe-
rience wasted or selfishly kept secret. A prac-
tical man can easily become a scientific one by
simply recording the results of his experience,
taking an interest in the application of the
knowledge acquired, and giving others some
benefit from what he has learned. The real sci-
entific man is at the same time practical, else he
is a mere theorist and his ideas worthy of little
consideration.

The every-day work in our mines and mills,
when recorded, described and applied else-
where, is as much science as any of that which
we get from the German books or universities.
The advantage they have over us is, that
they have, or take, the time to make a matter
of record of all that happens in their daily
business, so that others may benefit by their ex-
perience; while people in this country are either
too busy or, too careless to do any such thing.
It is unfortunate that this is so, but it is the
fault of the people themselves. In a measure
the numerous newspapers in the country remedy
the evil and help to make science out of prac-
tice, by recording such things as come under
their observation. The PRESS has always done
what it could in this direction, and only needs
the assistance of the practical men of the
country to do a great deal of good. If our
millmen would only take the trouble to let oth-
ers know what they find out, and not make a
secret of it, they would benefit others and not
detract anything from their own knowledge.
The experience which has been gained in the
practice of California and Nevada has been ex-
ceedingly valuable, although it is not as satisfac-
torily a matter of record as it might be. We
have had so many classes of ore to deal with,
and so many varying conditions that we have
had to try all kinds of experiments, some of
these have been failures and others have proved
successful. We have branched out from the old
systems of mining in many particulars, and
made many new departures in metallurgical
practice. All this is of great interest abroad,
but others depend for their knowledge of
these things almost entirely on the newspapers.
Still we, having the practice, have the basis of
the science, and it is our own fault if we allow
others to claim the latter as their own.

Salting the Bullion.

A week or so ago there was a wholesale dis-
charge of miners from the Bullion mine for an
alleged "salting" of rock by which the insiders
lost some money. It seems that on the 2000-
foot level and in the north drift, some excellent
indications were found, and to hurry up matters
it was determined to take long hand-drills and
send them on ahead and assay the pulp as it was
drawn out. This worked well, but some one
"played" the managers. He took some rich
ore and powdered it, and mixed it with the pulp
formed by the drill. The assays ran into the
hundreds, and the "inside" loaded up with
stock for a rise. When the drift got to where
the rock was supposed to come from the trick
was exposed. As it was impossible to find the
guilty man, the whole force on that level was
discharged. The worst of it was that the drop
in the market came just after the load-up above
mentioned, and consequently the loaders are
caught.

Since then all the men have appeared before
a Justice of the Peace and made oath that they
did not, at any time, tamper with the rock
they were working, or salt it in any manner,
and that they had no knowledge who had done
so. After this it was no more than fair that the
men should be reinstated, especially as employ-
ment is scarce just now in that part of the
country. It seems, however, a good judgment
on the insiders, who were laying to catch some
one else, and got caught themselves. A few
lessons of this kind would be wholesome, and
probably the man who did the "salting" had
that in view, and did it to catch the very per-
sons he did. At all events nobody has much
sympathy with people who keep ahead of a drift
with a drill to take advantage of other stock-
holders who do not happen to be in the manage-
ment. All sympathy is with the poor fellows
who lost their places on account of the affair.

Foundry Notes.

Although business at the foundries is by no
means as lively as it might be, all of them have
some work on hand, of course. Work has been
taken this year at less prices than heretofore,
so that profits have been lighter as well as
work scarcer.

At the Etna Iron Works

They are keeping a full force of hands all the
time, and their trade has been pretty good of
late; in fact, for two months as good as cor-
responding months last year. They are building
at present one of Wilson's two-stamp steam-
stamp mills, on an improved plan. This is to
be taken to Globe district, Arizona, and a
White rotary furnace will accompany it. A
company are taking it down there who are to
work it as a custom mill as well as for their
own mines. In this mill the valve motion is
changed from those previously made and bal-
ance valves put in. With the old style it took
about half of the power to move the valves, so
that the new mill will work much better. It
will have a four-sided discharge, and be set on
four iron columns, having no wood about it.

At these works they are also building a new
rotary pulverizer, which will be completed in a
few days. As soon as it is finished and tried
we shall describe it in detail. They have cast
a large five-ton propeller for the steamer *Ajaja*.
This is a fifth one cast from this pattern, the
largest ever cast in the State. It is four-bladed
and 14 feet in diameter. They are also doing
some work for the steamer *Neuborn*. They are
re-boring a cylinder and putting in Dunbar pack-
ing at the Alviso flour mill. They are doing
the usual jobbing and small work.

The Golden State Iron Works

Have considerable small work on hand. They
are making a lot of Frue concentrators to be
worked on the gold beach sands, where they
have proven successful. They are doing con-
siderable work for the Napa Consolidated quick-
silver company and also for the Cloverdale and
Sulphur Banks' companies; also doing the iron
work for the new railroad bridge over the Rus-
sian river, being built by the Pacific bridge com-
pany. They are making some amalgamating
machinery for the Manzanita mine in Colusa
county, of which we spoke of last week. A
considerable amount of castings is being made
to go to Virginia and Gold Hill.

They are making quite a number of the
Golden State pressure and suction blowers
principally for quicksilver mines. One is being
made for use in ventilating a dairy and keeping
the temperature even. A small stream of
water is conducted to the pipe connecting with
the blower, and the blower throws it in a fine
spray into the milk-room. We understand
that this principle has been applied with suc-
cess at the dairy of Hon. C. S. Abbott, Salinas.

At these works they are also making some of
Thomas Guerin's patent main sewer traps,
an invention particularly useful in a climate
like this where we have such long dry seasons.
It is intended for use at the corners of streets
where the water from the streets flows into the
sewer. It consists of a vertical pipe in which
is placed a wooden valve, so as to shut the cess-
pool off from the main sewer when there is no
water running. When there is water to run,
the wooden valve or float, rises and allows the
water to run off, closing automatically after the
cesspool is drained so as to keep the sewer gas
from escaping into the street, as it does by the
present system. To use these traps, there is no
change necessary in the present cesspools, ex-
cept to remove the present iron arch and insert
the pipe and trap. By the use of this appara-
tus no sewer gas is allowed to escape into the
streets, to the detriment of the health of the
city. The trap has been examined by the
health officer and pronounced good.

BULLION SHIPMENTS.—Since our last issue
shipments of bullion from prominent mines have
been as follows: Grand Prize, April 30th, \$6,596;
Modoc, May 1st, \$5,633.70; Northern Belle, 1st,
\$7,900; Comanche, 1st, \$8,770; Northern Belle,
3d, \$8,286.12; Con. Virginia, 5th, \$244,326.83
—total to date, \$845,657.37; Modoc, 3d, \$6,
717.90—total to date, \$12,351.60; Grand Prize,
5th, \$6,800; Northern Belle, 6th, \$11,794.21;
California, 8th, \$230,165.70—first shipment for
May account; Con. Virginia, 8th, \$106,157.24
—April account to date, \$951,814.61; Modoc,
7th, \$6,658.42—total to date, \$19,044.60.

THE Mechanics' Institute held a meeting this
week, when S. H. Wheeler, Joseph Britton,
James Patterson, A. S. Iredale and I. M. Scott
were appointed to nominate seven Directors to
serve for the ensuing two years. At this meet-
ing a resolution was adopted, suggesting the
appointment of Prof. Geo. Davidson, President
of the California Academy of Sciences, as a
member of the Board of Regents of the State
University, to fill the place of the late John B.
Felton.

A boy found 400 pounds of amalgam in an
old tunnel near the Kelsey mill, near Silver
City, Nev., last week. The amalgam had been
placed there recently, and was in all probability
stolen from one of the mills near by.

It is said that the Nevada bank helped the
Martin White company, of Ward district, out
of its financial difficulties.

Hard Times on the Comstock.

The phrase of "hard times on the Comstock"
would have sounded queerly a year ago, but
there is more truth than poetry in it now. The
depression in the stock market and lack of faith
in mining securities, has naturally operated to
the injury of the mines. All of the large mines
on the Comstock have reduced the working
force, and many of the "outside" ones have shut
down altogether. When such mines as the
Yellow Jacket only keep a dozen or so men at
work, the chances for miners to find employ-
ment are slim. The discharge of workmen con-
tinues daily, and with many it is no longer a
question of making a fortune, but one of ob-
taining the common necessities of life. Only
this week we read in the local papers of the
case of a mother and three fatherless children
being found starving to death. The people
there are just awakening to the misery and des-
titution which exist in their midst, and it has
been suggested that a relief committee be ap-
pointed.

This state of affairs, in what has been consid-
ered the most prosperous mining town on the
Pacific coast, is truly deplorable. Miners who
find no employment there have no where else to
go to get it, as all the camps have the same
trouble. Business is dull at all of them and
times hard. Some are thinking of going to the
Black hills and others to Arizona, but both are
bad places for a man "without a stake." It
seems strange to an old resident to hear of such
rough times on the Comstock, as it has always
been the miners' Mecca, where work could be
found when other places were dull. Now,
however, it is as bad as, if not worse than, other
localities, and many there have not means to
leave if they knew where to go. In speaking
of the prevalent distress, the *Enterprise* says:

It looks now as though in a few days more it
will be a question for landlords to decide
whether to accept less rents or to have tenant-
less houses; a question for railroad corporations
whether to charge less freights or to cease run-
ning trains; a question for laborers, whether to
take less wages or cease laboring at all; a ques-
tion for everybody, whether a half-dollar can
be made to go as far as a dollar did a year ago,
or whether to go without the half. The mines
are daily discharging workmen. The number
of destitute and desperate men and families are
increasing daily. The situation is very serious.
What the cause is or who is to blame is a second-
ary matter; the question now is, what is it
best to do? We think there should be a relief
committee organized at once. Of our own
knowledge we know that there are delicate
women and little children here who have not
any sufficient food or clothing. The safety of
the property-holders demands that these people
shall be looked after and provided with what
they absolutely need at once. There are dozens
if not hundreds, of strong men walking our
streets half crazed for want of work and bread,
and wild with anxiety for their little ones.
There is a limit beyond which these men will
not go, and the time comes to a man at last
when he says "I don't care." A great calamity
fell upon Virginia a year ago last October. In
five hours the main portion of the city was
lifted up in a whirlwind of fire and carried
away. Every heart was open then and every
exertion was made to rescue and relieve suffer-
ers. Our people should remember that a calam-
ity, four-fold greater in its immensity, has
fallen now upon our city. The only difference
is that it has been coming for five months in-
stead of having been precipitated in five hours.
Men before had no houses, but they had work
and could buy food. Now they have shelters,
but no work and no money. We do not wish
to be thought an alarmist, but, in all truth and
seriousness, we say that there is such terrible
suffering here now as puts the city itself in
danger. We invoke our rich men to meet and
consult and see if some work cannot be found
for our most needy laborers; we commend to
citizens generally the need of organizing to try,
with a concerted movement, to inaugurate a
system of charities which shall feed and send
away our most deserving poor; and to all we
commend the utmost charity and forbearance.

MECHANICAL ORE CONCENTRATION.—The se-
ries of articles on mechanical ore concentration
and separation, by Mr. F. M. F. Cazin, M. E.,
of Santa Fe, New Mexico, is concluded in this
issue. The article, as a whole, is very valuable,
and stamps Mr. Cazin as a practical and well
posted man in his specialty. He informs us
that he has elaborated the articles published in
the PRESS and will probably present the whole
in book form before long. The treatise is the
most complete on the subject which has been
given in this country, and is rendered more
valuable to us from having been written by one
who has had so much practical experience in
American mines. The subject is one of great
importance on this coast, where it has been too
long neglected. Mr. Cazin deserves great credit
for his valuable compilation of facts concerning
concentration, and as much of what he has
written is the result of his own experience, an
elaboration of the treatise will be valuable to
the mining community.

Mechanical Ore Concentration and Separation—No 25.

(Written for the PRESS by FRANCIS M. F. CAZIN, M. E., Santa Fe, New Mexico.)

Equal Falling.

In a vertical upward stream of water, the streaming action supplements within a limited vertical space (column), what this space (column) may lack in height for permitting two particles of solids of equal size, but unequal density, to separate locally, in a degree sufficient for practical application. If, therefore, motion is required in order to utilize the difference in density in practice within water for separation, according to quality, such motion (power, fuel) is required in a higher degree in using a liquid of less density than water or air. This involves a greater amount of expense in using air than in using water for motive power for gaining the same effect.

The same tendency shown by unequal falling particles to differ in their rate of motion in a column of water without motion, and in an upward vertical stream, is shown also in a horizontal stream, as well when the particles of solids are suspended free in such horizontal stream, as when these particles of solids are in contact with the floor on which the horizontal or inclined stream is in motion.

In practice all four modifications are utilized, either singly or in combination, and the following supplementary axioms govern the action:

First. Of two particles of solids being either free in suspension in a horizontal or inclined stream of water, or in contact with an even floor it runs on, being of equal size but of unequal density, the particle of less density will be carried to the greater distance.

Second. Of two particles of solids in a horizontal or inclined stream of water being in contact with an even floor on which the stream runs, being of equal falling but of unequal size and density, the one of larger size but less density will be carried to the greatest distance.

But in pursuing the course of experiment further with regard to the even floor (horizontal or inclined plane) on which the particles of solids are to move by a stream of water, we find that a separating motion may be imparted to the particles by and in their contact with the solid plane (floor) they run on, and then find the further axiom.

Third. Of two particles exposed to a horizontal or inclined stream of water when in contact with an even floor (plane), such particles being either of equal size or equal falling but differing in size, the particle of greater density will, when the solid floor receives a percussion, either contrary to direction of stream or in a right angle, it will either be arrested or be made to recede to a greater extent than that of less density; and the difference will be the larger, the more equal in size the particles differing in density.

By these axioms one conclusion must by necessity be arrived at—the necessity of assorting according to size before entering into any action for separating according to quality. There is only one case where equal falling will act for equal size. This is where the particles are in contact with an even floor.

This quality of equal falling is therefore utilized where the minuteness of sizes does not longer permit mechanical assorting for preparing material (slimes) for the separating action as shown in the proper place.

Conclusive Remarks.

The preceding treatise has been begun when the author was temporarily free from practical work in his special line of action, and has been completed when again under the pressure of daily duties. This, and the great distance between San Francisco and Santa Fe, preventing him from reading proof-sheets, have not only permitted many imperfections and even errors to escape, but even occasioned the misplacement and falling out of chapters; but nevertheless what has been said will prove of real practical benefit wherever needed and heeded. It is the author's intention, when spare time arrives therefore, to make this treatise the skeleton of a complete one in book shape; but he is in hope that the present one will be useful in drawing closer attention to the great importance of mineral dressing in our mining industry, and would be well pleased to thus have been useful to the development of the immense resources of this country.

PICNIC OF SANTA CLARA COUNTY PIONEERS.—We acknowledge the receipt of a card of invitation to attend the above named festivity which will occur at O'Donnell's gardens, San Jose, Friday, June 22d. The occasion will doubtless be one of much enjoyment to the pioneers and their guests. The picnic is under the auspices of the Pioneers' Association, of which Coleman Younger is President and A. P. Murgotten is Secretary.

The Crown Point mining company having found it necessary to increase their pumping facilities in order to handle the water on the 2000-foot level. The Dayton mining company are going to let them have their big No. 7 air-compressor for use until such time as new pumping machinery can be obtained from the East.

The O'Harra Champion Furnace.

The O'Harra Champion furnace at the Exchequer mill, Alpine county, has been accepted by Manager Chalmers for his company, and he is so well satisfied with its work that he has ordered one of the same capacity for the I X L mill. We gave some time since a description of this furnace, but it has been so successful in Alpine county, and so much interest is manifested just now in furnace work that we give herewith illustrations showing the construction, and take the following description from the *Alpine Chronicle*:

The furnace is perfect in its mechanical arrangements and runs like clock work. It has not been stopped a moment on its own account since starting. Before seeing the furnace at work we had some doubts as to the iron work standing the heat, but after seeing the plows and chains moving through the flames and red

the lower hearth it gives up a portion of its sulphur, and changes to a sulphate. After passing the first fires it receives oxygen from openings on each side of the furnace, and from that on the chlorination progresses. As it is moved toward the second or last fires, the draft is so arranged that it is equally divided and looks as though it hardly knew which way to go—in fact the chlorine gases arising from the bed of ore stop there, hovering over the ore as the plows expose a new surface every minute, thereby causing the ore to chloridize to very near 100 per cent. of the fire assay. For instance, on an average sample of a forty-eight hours' run on low grade ore (that was run through to get it out of the way) the chlorination was found to be 94 per cent.—within six per cent. of the fire assay. The furnace was built for a thirty-ton furnace, but it is found that it will easily work forty tons in twenty-four hours. With this furnace a number of steam pipes, with superheaters, are connected and so arranged as to throw jets of steam, and cause a rush of oxygen to mix with the flames, but it is found to be unnecessary to use them on the Exchequer ore, as the bullion is 960 fine.

FIG. 1. SECTIONAL SIDE ELEVATION OF FURNACE.

hot ore, and coming out of the furnace almost cold, we are satisfied that they are little, if any affected by the heat and gases, and the secret of this is, they are in the heat only half a minute and out in the cool air one minute and a half, consequently they have no chance to become over-heated while the furnace is running, and when it is stopped the chain is lowered in a groove or opening in the hearth out of the heat by slackening the chain at one end where the shaft is on a carriage, and so arranged as to be tightened or slackened by a ratchet. For the

The cost of roasting 20 tons of ore in 24 hours is as follows:

One man.....	\$ 4 00
One man.....	3 00
Wood—13 cords, at \$3 per cord.....	5 25
Salt—1,000 pounds, at 2½ cents.....	40 00

Cost of 20 tons.....	\$52 25
Cost of one ton.....	2 61½

Mr. O'Harra says he can build a 100-ton furnace that would make the cost of roasting much cheaper. We learn that the Advance company, at Monitor, are negotiating with Mr. O'Harra

FIG. 2. BOTTOM HEARTH OF FIFTY TON FURNACE.

benefit of those that have not seen the furnace we will try to give a description of it. It is 85 feet in length, with two hearths, one above the other, as two furnaces, each seven feet wide. There are five fire chambers, one on the upper hearth which is used only for heating the furnace, after which the fire is allowed to go out, as the heat and gases arising from the lower hearth is sufficient to heat the ore and prepare it for chloridizing on the lower hearth, on the sides of which there are four fires, two on each side.

for the erection of two 30-ton furnaces this spring. The people of this county may rejoice that our rebellious ores have at last been subdued. Alpine is wealthy in her mountains, and capital, to be well directed by energetic men, would soon place her in the front rank with the best mining districts in the world.

Since the above was put in type Manager Chalmers informs us that since the furnace was accepted by him it has done its work still better—working up to 100%—up to the full assay

FIG. 3. THE O'HARRA CHLORIDIZING FURNACE.

There is an endless chain that moves through a groove in the furnace and around large sheaves at each end and over the top outside. To this chain is attached two triangular frames, and to these frames are fastened a number of plows, so arranged at a certain angle as to turn the red-hot ore to the right and then to the left, and at the same time move it forward a little every time they plow through it. The heat arising from the lower furnace ascends to the upper hearth through the flues and ore shutters, and is brought to bear on the ore as it is discharged from the battery and fed to the furnace and moved forward by degrees by the plows, prepares it, or heats it up, evenly and gradually, ready for the chloridizing heat of the lower hearth. When it reaches the opposite end from where it is fed it drops through an opening or shutter to the lower hearth or lower furnace; from thence it moves in contact toward the discharge end and through the flames, a space of about seventy-five feet. As the ore is moved forward in contact with the first fires of

value—stamping it as the best reduction furnace in existence.

MINING SUIT.—H. S. Moore has filed a suit in the Twelfth District Court, against Isaac Yoakum et al., to recover possession of the Long Tom, Ophir, Gould & Curry No. 2, Cornelia McDonald, Josephine, Sam Patch, Mammoth, Ingomar and Isabel mines, known as the Long Tom mining property, quartz mills and other property, and \$75,000 for the withholding and use of the same. The plaintiff also prays for an injunction restraining defendants from working the mines during the pending of the action.

Owing to the stringency of the times and the heavy expense in conducting mining and prospecting operations, the Yellow Jacket mining company find it necessary to discharge the greater portion of the men in their employ at the present time and to reduce expenses in every way possible. Only enough men will be retained to keep the old works running and sink the new shaft.

Amador Mines.

We had the pleasure of a call this week from Capt. Beck, of Jackson, Amador county, and Mr. John Clements. These gentlemen have been in the city about 10 days in order to place some gold mines of Amador county. They have sold the Good Hope and Pioneer mines, near Jackson; both to Eastern capitalists. The mines have been bought and the money paid. Capt. Beck is now getting drills, pumps and other machinery, to go immediately at work to develop the properties for the parties to whom he has sold. Both gentlemen say they found no trouble in selling the mines, everything having been accomplished within the few days of their stay. The mines are rich and there is no doubt the investors will get a good return for their money.

Mr. Beck has also purchased one of W. C. Wilcox & Co.'s new pattern pumps for his own mine, the Bismarck, and will take it back with him. He is very much pleased with the appearance of the pump, and is sure it will do first-class work. At the Beck mine they have 46 feet of ore. This and the other mines were first worked by Mexicans, who, when they came to work in their shafts—four of them—gave up work. Mr. Beck is an old Lake Superior miner, and has been in Colorado, Utah, Arizona, etc., but thinks Amador county, in this State, has the best and richest mines he has met with. The prospects are better there, he thinks, for honest, legitimate mining, than any place he has seen. The gold mines are rich and only need intelligent development to make them very profitable.

The dry weather of the past winter has been favorable for quartz mining as they have been able to prepare everything for work, and have been less troubled with water than usual. Capt. Beck thinks the mines right at our own door would be more profitable investments than if our capitalists went further off. To get to Jackson you leave here on the C. P. R. R., at 8 A. M., and go to Galt station; from there to Ione, on the Ione railroad, and thence to Jackson by stage, arriving at 5 P. M. Any one owning mines in that vicinity, can run up at any time and see how they are getting on, and as communication is speedy, there need be no delays about work.

Items of Interest from the Mines.

We give below items of interest from prominent mines, most of which are collated from letters of the respective Superintendents on file at the offices in this city:

They will commence opening a station at the 1900-foot level of the Ophir next week.

In the Justice, owing to the great size of the ore chamber, above the 400-foot level, the same being a perpendicular height of 125 feet, by 136 feet in length, the overhanging wall presses with such force against the timbers that the expense is very great; 600, 700 and 750-foot levels, north lateral drifts are still in a very promising condition.

They are using the Ingersoll drill in the Utah mine.

During the month of April the Manhattan mill reduced 573 tons of ore; assay value \$90,866.

They struck a new body of ore in the Ready Cash of the Steptoe Con. Co., which is somewhat different and better than any heretofore found in the mine.

All the various ore stopes in the California mine are looking well. They are producing some 515 tons daily.

The south drift on the 1650-foot level of the Con. Virginia is being advanced as fast as possible, but will require some days yet to reach the deep winze. The rock is hard and heat intense.

The face of the north drift of the Advance is said to be in pay ore.

They think they have good prospects for a large body of ore in the DeFrees mine.

In the Yellow Jacket mine what little water is found in the bottom of the winze below the 2040-foot level is sent up to the 1740-foot level by a pump worked by compressed air, from which point it is sent to the surface by the main pump. A syphon is now being put in to run the water from this point across through a drift to the 1850-foot level of the Crown Point and Belcher pump shaft. If this should be successful it will do away with the necessity of running the heavy main pump of the Yellow Jacket. The idea is to run the old works as cheaply as possible, and yet keep the prospecting of the mine going forward, while the new shaft is being sunk.

The yield of the California mine in April was \$1,558,722.44, of which \$817,046.56 was gold and \$741,674.88 silver.

The flow of water in the Crown Point has been so great in the face of the drift, on the 2000-foot level, that it has not been safe to attempt its advancement during the past week. In the meantime, however, the northeast drift on the same level, which will cut the ledge diagonally with its main course, has been advancing through a stratification of quartz and porphyry identical with that developed in the east drift. This drift will also soon have to stop as it will not do to tap the water at two different points at the same time. The quartz found in the face of the northeast drift assays from \$5 to \$7 per ton, being identical with that first struck on that level.

The Great Suspension Bridge between New York and Brooklyn.

The work of arranging, testing and preparing for the laying of the wires of the main cables is steadily progressing, and is watched with much attention by engineers and others interested in this remarkable work. As a matter for convenient reference, we subjoin the following epitome of principal facts and dimensions:

Construction commenced, January 2d, 1870.
Length of river span, 1,595 feet, six inches.
Length of each land span, 930 feet (1,860 feet.)

Length of Brooklyn approach, 971 feet.
Length of New York approach, 1,562 feet, six inches.

Total length of bridge, 5,989 feet.
Width of bridge, 85 feet.
Number of cables, four.
Diameter of each cable, 15½ inches.
Each cable consists of 6,300 parallel (not twisted), steel wires, No. seven gauge, closely wrapped to a solid cylinder.

Ultimate strength of each cable, 11,200 tons.
Depth of tower foundation below high water, Brooklyn, 45 feet.

Depth of tower foundation below high water, New York, 78 feet.

Size of towers at high water line, 140x59 feet.

Size of towers at roof course, 136x53 feet.
Total height of towers above high water, 277 feet.

Clear height of bridge in center of river span above high water, at 50° Fah., 135 feet.

Height of floor at towers above high water, 119 feet three inches.

Grade of roadway, three and one-fourth feet in 100 feet.

Size of anchorages at base, 129x119 feet.
Size of anchorages at top, 117x104 feet.

Weight of each anchor-plate, 23 tons.
Estimated total cost of bridge, exclusive of land acquisition, \$9,000,000.

Estimated cost of land, say, \$3,500,000.
Total estimated cost, \$12,500,000.

Experiments Made by the Eastern Railroad Association.

The Springfield, Mass., *Republican* of recent date says: A very interesting series of experiments have been in progress on the Boston and Albany road the past few days by means of the dynamograph car of the Eastern Railway Association, in charge of P. H. Dudley, which has been run between Springfield and Worcester on both freight and passenger trains to test the relative amount of power required at different points along the road, especial reference being had to the Springfield and Charlton grades. The experiment on the Modoc train east, leaving Springfield at 6:30 A. M., which, on the day in question, consisted of two sleepers, four passenger and baggage cars and the dynamograph car, showed power required as follows: For the first 2,920 feet out of the depot the tension on the draw-bar was 6,526 pounds; for the next mile 6,460 pounds, the rate of speed being 32 miles per hour; for the next, 6,200 pounds, the speed being 36 miles; and for the last 1,100 feet to the top of the grade, 6,250 pounds. The last mile required the engine to produce 19,625,800-foot pounds of power per minute, the term foot-pound indicating the power required to lift one pound one foot. In going up the grade from East Brookfield to Charlton, beginning at the station the tension on the draw-bar for the first 3,880 yards was 5,722 pounds; for the first full mile, the velocity being 37.5 miles, 4,250 pounds; for the second mile, with 37 miles velocity, 5,232 pounds; third, with 36 miles velocity, 5,450 pounds; fourth, which contains a sharp curve, with 37 miles velocity 5,612 pounds; fifth, with 41 miles velocity, 5,230 pounds; and sixth, which ran a little past the summit at Charlton, 4,356 pounds. The engine had an 18 by 24 cylinder, and the track was in excellent condition. The maximum of the Springfield grade is 60 feet to the mile and the Charlton grade 51.47. At the sharpest curve the grade is about 49 feet. Similar experiments were made on a freight train of 27 cars drawn by the Adirondack, famous for her trials with the Mogul engine last summer, and showed that the tension on the draw-bar going up Springfield grade at a speed of 5.9 miles per hour was about 16,000 pounds, and the average strain going up Charlton grade at an average speed of about nine miles per hour was 14,500 pounds, the power required in the first instance being 84,840,000 foot-pounds. Near the top of the grade the power of the engine was tested by applying the brakes and it was found that, running at four miles per hour, the engine could exert a tension of 17,000 pounds. Beyond this point the drivers would slip and little progress was made.

Really, the most important experiments in which the Association is just now engaged are in testing the quality of iron and steel used for bridges, rails, axles and car wheels. Recent trials of the tenacity of iron used for various bridges and car axles indicate that much of the iron in use will only stand about two-thirds the strain which it is guaranteed to resist. For instance, some iron now being put into a new bridge at the East, which is supposed to stand a pressure of 60,000 pounds to the square inch, breaks readily at 40,000 pounds, and a car axle supposed to be equal to 110,000 pounds snapped at 70,000. When it is borne in mind that the calculations of bridge-building engineers are based on the guaranteed strength of the irons

the reason for the fall of iron bridges become, apparent at once, and, instead of wondering at an Ashtabula horror, the wonder rather is that it is not repeated.

The Eastern Railroad Association, which is making these experiments, is composed of all the railroads on the Atlantic coast north of Richmond, Va., and east of Pittsburgh and the Alleghenies, and was organized about 10 years ago, having for its object the investigation of the validity of patents and claims to royalties for the use of the same. S. M. Whipple, of South Adams, is the General Agent. The scope of the Association has naturally broadened, and it has been for the past few years largely engaged in testing the merits of various railway equipments with the idea of getting the best in every department. The dynamograph car is a curiosity in itself, containing, besides the dynamograph, which is a wonderful instrument, registering exactly the amount of power to pull a train, a chronograph which records the speed of the train every seven and a half seconds, an anemometer which registers the velocity of the wind, whether natural or caused by the motion of the cars, and a complete set of instruments for testing the hardness, tenacity, ductility, density and amount of carbon in rails, axles and the like.

The Dives Mine.

The Colorado *Miner* says: We have been down in the Dives—down and through and out by way of the Diamond tunnel, 650 feet below the surface at the discovery. A trip through this celebrated mine suggests enough to more than make a book; stories connected with the men and stirring times in the history of the Colorado silver mines occur to the mind, and one feels like he was walking over an old battle field. At present, however, we must be confined to the simple story of what you see in going through the mine.

Passing through a tunnel 730 feet long, you arrive at the engine chamber, which is scooped out of the rock, 24x30 feet, and timbered like an Episcopalian church, only the rafters are big pine trees. The engine and boiler are delightfully clean and bright—the engineer is evidently proud of his place. This is on the south vein of the Dives lode. Another similar chamber, but not so large, is found on the north vein, and the same boiler furnishes steam for both. One of these, the first, does the work for the Purdue company, or West End—the other for the East Dives.

We go into the East Dives first. The ladders are dry and safe, and we have time to look about as we pass from one level to another, reaching finally a depth of 520 feet. The material used in timbering is the best to be found in this county; the work done is first-class in every particular. It is surprising to find such good work with such a stormy history. The ore vein is never lost—its value and size changes, but it is always in view and always good and strong. Experts have estimated that it would average two feet through the entire workings, and to us this seems a reasonable conclusion. From the bottom of the East Dives mine we return to the seventh level, pass over into the Purdue mine, and descend to the bottom or to the level of the Diamond tunnel, and come to the surface again. This tunnel is over 1,200 feet long, and has only recently broken into the Dives mine.

We have now passed nine levels, having an aggregate length of 1,840 feet. The work at present is done from above by the two engines alluded to, which are each 45-horse power. The ore passes out through what is called the slide, which is substantially boxed up with heavy plank. An iron bucket attached to a large rope which runs on a great spool, regulated by a friction brake, lifts the ore to the engine room, and a car carries it to the ore house. In the various levels there are similar iron tracks—T-rails—and cars to carry the ore to the main shaft.

The Dives began to attract public attention in 1872. Since that time it has produced a million and a quarter of money. The ore deposit was not only large but rich, running as high as 300 ounces per ton, and as much as eight feet in width. In going down the deep shaft we passed solid blocks of mineral eight feet thick.

The west end of the vein is owned by an Indiana company (the Purdue) organized by John H. McMurdy in Lafayette, Ind.; the east by the estate of John H. McMurdy, John A. Logan and others. Hon. William A. Hamill is the agent and Superintendent for both. An immense amount of money has been spent in working this vein and has all come out of the ore produced. The pay roll of both concerns has been over \$25,000 per month; a whole forest of trees has been used up in timbering this mine; and an army of men employed in doing the work. At times every wagon and teamster in the county has been employed in hauling the ore to market.

The cutting of the vein by the Diamond tunnel ought to be a great benefit, but this will depend upon the good sense displayed by the parties in interest. Should they meet each other with reasonably conservative views, it will be a mutual good thing, and a great public benefit. Should the Pelican, Dives and Diamond tunnel consolidate, it would make the most valuable and productive piece of mining property in Colorado. The engines could be lowered to the Diamond tunnel level, and the vein explored to a depth of 1,000 feet below that point. Meantime, the reserve ground now above that

level would furnish the necessary funds, besides leaving a handsome profit to the owners.

Mr. Hamill's management of this property has compelled the respect and admiration of the general public, and those who have had the best opportunity to examine the mine are loudest in his praise. We cannot close a notice of this mine without a reference to one of the miners who has contributed much towards keeping it in good shape, M. T. Sandals, who has been a lessee on the Dives since 1872.

Manufacture of Ammonia.

In some cases the gases evolved in blast-furnaces used in manufacturing iron and the cyanogen combined with them are allowed to escape into the atmosphere, but in other cases they are conveyed in tubes under steam-boilers to generate steam. With a view the better to utilize them, Messrs. Israel Swindells, of Warrington, and Robert Lancaster, of Widnes, propose to inject superheated steam into the tubes containing the gases and cyanogen, either before or after they act on the steam-boilers, the steam, gases and cyanogen thus combined are passed through incandescent fuel, and the vapors thus formed are condensed by any well-known process to produce ammonia. In carrying out the invention, they take from any conveniently formed blast-furnace for smelting iron, the gases and cyanogen therein generated, and pass such gases in combination with highly superheated steam through any conveniently formed pipe or pipes into a closed and highly-heated iron retort or clay furnace, of suitable size and dimensions, and erected in a vertical or other position, into which incandescent fuel or other material may be inserted. In superheating the required steam, they prefer to adopt the means employed in iron-smelting furnaces for heating the hot blast.

The combination of gases thus emitted in the latter process are further conveyed through any convenient form of pipe into a solution of lime, cream of lime or other caustic base, when it is found needful to absorb all or any portion of carbonic acid which may exist in conjunction with the remaining gases. The residue of these gases are also further conducted through suitably formed pipes into a highly-heated closed vessel or chamber, filled with broken bricks or other material, to combine the latter gases and thereby produce ammoniacal gases, which gases may be passed through, cooled down and condensed in towers constructed of any convenient material, form and dimensions, into which broken bricks or other material may be placed, or by any other known process of condensation. In the manufacture of muriatic or other salt of ammonia, the muriatic or other acid must be poured into the top of the condensing towers to meet the ascending vapors, but without the use of acids, caustic and carbonate of ammonia may be produced. —*London Mining Journal*.

MINES SOLD.—Messrs. Alvin Potter and James Sallee have sold their mine near Teel's marsh to Dr. Webber of Virginia City, Mr. J. R. Murphy, and another party whose name we did not learn. Mr. Sallee informs us that the price paid for this property was \$55,000. For the past few months this mine has attracted considerable attention from the fact that it has been the chief source of the ore supply of the Gen. Thomas mill, where it has been worked to a large profit, and at the same time they have shipped their highest grade ore to San Francisco, with like good results. If the mine is really as good as it is believed to be by the many miners who visited it recently, the price paid is but a small part of its value, while at the same time it is by far the largest sum ever paid for a mine in this vicinity. Messrs. Potter & Sallee well deserve the success they have met. They have worked long and patiently, starting out with poor assays and good indications, they followed their prospect to success. We hope their good fortune will encourage other miners hereafter to stick to their claims until they develop mines which will command purchasers. Since the above was in type we have received a note from "Max" stating that the same parties also purchased the Comanche mine, in the same vicinity, from H. J. Keene. The company intend to build a mill for the reduction of the ore, and have put twenty-five men to work on the mine under the superintendence of J. R. Murphy, who is well-known in mining circles. —*Borax Miner*.

NEW SULPHURET WORKS.—To keep pace with the rapid development of the mineral interest in the northern part of the county, C. J. Garland is putting up sulphuret works, about half a mile from Drytown, on the road leading to New Chicago. The brick for the ovens is being made on the ground. The frame work consists of the building that used to stand on Sutter creek, previous to the construction of the large works near the Lincoln mine. Mr. Garland is thoroughly acquainted with the business of extracting the gold from sulphurets. During the many years in which he has carried on this industry in Amador county, he has given every satisfaction to the mine owners. While the Sutter creek establishment will still continue to be the principal place for the reduction of sulphurets, yet Mr. Garland is enterprising enough to retain the business in his own hands by throwing out branches in keeping with mineral development. The new works near Drytown will be a great accommodation to the mines of Plymouth, Drytown, and around the Grover mine and the lava beds. The item of freight to the Sutter works was so great as to

render the putting up of another reduction works only a question of time. Mr. Garland is shrewd enough to perceive this, and has moved in the matter with commendable promptness. —*Amador Ledger*.

Idaho Mines.

The Owyhee *Avalanche* says: From different sections of the Territory the reports we have relative to the prospects and progress of mining operations this season are quite satisfactory and cheering. While there will not probably be the usual yield from placer claims in consequence of the light snow falls during the past winter, there will nevertheless be a much heavier gold product than was generally supposed, and the present outlook is upon the whole rather favorable. A new impetus seems to have been given to quartz mining operations in the Basin, Alturas, the Heath district and other camps, and it is within reasonable limits to predict that bullion shipments from all the principal mining districts of Idaho will be larger the coming summer than they have been at any corresponding period for the past seven years. One of the principal drawbacks, to the success of mining operations here as well as in other parts of this Territory has been found to consist in the unsuitable character of much of the machinery in use at the mills. Much treasure has been lost from this cause which a different process of reduction, either by roasting or otherwise, might have saved. The attention of parties interested is being directed to this pressing want, and the requisite machinery is being gradually supplied at points where it is needed most.

In this immediate vicinity, the mining outlook remains about the same, with prospects rather cheering than otherwise. There is every prospect that the South Chariot, Empire and Poorman will be in full blast within the next ten weeks. There are fortunes to be made from the judicious working of any one of these mines, and it is a satisfaction to know that such valuable mining properties are not to remain idle much longer. Idaho has better mines to-day than any other country in the world.

A LOST GOLD MINE FOUND.—The great gold mine of Los Cristales, at Cauquenes, in Chile, which has been lost for 40 years, has been found by three Englishmen. It was abandoned at a time when the Chileans were shooting each other and trying to overturn the government. It then filled up with water and an avalanche slid into and over it, and confounded all the geographers for 40 years in regard to its whereabouts. Now that it has been found it will be worked again by English capital.

ADVICES from Victoria, B. C., state that on the 29th ult. the militia companies started for the scene of trouble at the Wellington coal mines, where the miners are on a strike. They went fully equipped for active service. The gunboat *Rocket*, with the Sheriff's party has gone also.

MAY DAY was ushered in at Eureka with eight inches of snow. The storm has been general throughout the eastern portion of Nevada.

Mining and Scientific Press Patent Agency.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1860—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Steam Engines & Boilers.

NEW AND SECOND-HAND.

One Patent Straw-Burning, Portable En-
 gine, (new,) fire box boiler, the best
 Portable Engine on the coast; built
 by Ransom, Sims & Head, Ipswich,
 England.

One Steam Fire Engine, second-hand,
 in excellent condition, with 200 feet
 leather hose, very cheap, just the thing
 for a small town. Button & Blake,
 builders, Waterford, N. Y.

One second-hand Stationary Engine, 14x30
 inches, link motion, with or without
 hoist gear.

One second-hand Stationary Engine, 8x20
 inch, with or without hoist gear.

One Upright Boiler, Horizontal Engine
 on wheels, Eastern make, 7x12.

One Upright Boiler, Horizontal Engine,
 San Francisco make, 6x12.

One small Stationary Engine, 3½x7 inch.

One Steam Boiler, 40 inches diameter, 16
 feet long.

One 8x10 Straw-Burning Portable Engine.

One Traction Engine, three wheels, rub-
 ber tires, double cylinder, 6x10 inch;
 Thompson's patent, D. D. Williamson,
 builder, New Jersey.

 Send for Illustrated Circular.

San Francisco Cordage Company.

Established 1856.

We have just added a large amount of new machinery of
 the latest and most improved kind, and are again prepared
 to fill orders for Rope of any special lengths and sizes. Con-
 stantly on hand a large stock of Manila Rope, all sizes:
 Tarred Manila Rope; Hay Rope; Whale Line, etc., etc.

TUBBS & CO.,

611 and 613 Front Street, San Francisco.

HYATT'S LIFE BALSAM.

As a conqueror of Rheumatism, Gout, Neuralgia, and
 cure for Scrofula and all diseases arising from impurity of
 blood, the old and reliable Family Medicine, Hyatt's Life
 Balsam, stands unequalled, as proven by over 300,000 great
 cures during the past 30 years. Is a radical vegetable
 compound of Sarsaparilla, Dock, Guaiacum, etc., and a
 permanent cure. Sold by all druggists and country gro-
 cers. Take nothing else, and if they haven't it we will
 send by express, boxed, everywhere, at \$1 and \$1.25 per
 bottle; \$5 and \$8.50 half doz. HYATT & HYATT, 240 Grand
 street, New York.

PACIFIC RURAL PRESS,
 A first-class 16-page Illustrated Agricultural Weekly, filled
 with fresh, valuable and interesting reading. Every
 farmer and ruralist should take it. It is im-
 mensely popular. Send for a sample copy.

Metallurgy and Ores.

JOHN TAYLOR & CO.,

Importers of and Dealers in

ASSAYERS' MATERIALS.

Chemical Apparatus and Chemicals. Drug-
 gists' Glassware and Sundries, etc.

512 & 518 Washington St., San Francisco.

We would call the special attention of Assayers, Chem-
 ists, Mining Companies, Milling Companies, Prospectors,
 etc., to our large and well adapted stock of

ASSAYERS' MATERIALS

—AND—

Chemical Apparatus,

Having been engaged in furnishing these supplies since
 the first discovery of mines on the Pacific Coast.

Our Gold and Silver Tables, showing the value per
 ounce Troy at different degrees of fineness, and valuable
 tables for computation of assays in grains and grammes,
 will be sent free upon application.

JOHN TAYLOR & CO.

THOS. PRICE'S

Assay Office and Chemical
 Laboratory,

524 Sacramento St., S. F.

Deposits of bullion received, melted into bars, and re-
 turns made in from 24 to 48 hours.

Bullion can be forwarded to this Office from any part of
 the interior by Express, and returns made in the same
 manner.

Careful Analysis made of Ores, Metals, Soils, Waters,
 Industrial Products, Etc. Mines examined and reported
 upon. Consultations on Chemical and Metallurgical
 questions.

ARITHMETIC MADE EASY.

ROPP'S

EASY CALCULATOR

Is a new publication that must prove of incalculable
 benefit to Farmers, Mechanics and Business Men. It is
 so rapid and original as to startle the most scholarly,
 and yet so simple and practical that the most illiterate
 in figures can instantaneously become his own account-
 ant. It enables thousands to accomplish in a minute
 what they could not learn to calculate in many months.

The first part contains an entirely new system of tables,
 which show at a glance the exact value of all kinds of
 Grain, Stock, Hay, Coal, Lumber, Merchandise, etc.,
 from one pound up to a car load, and for any price that
 the market is likely to reach; the interest on any sum for
 any time at 6, 7, 8 and 10 per cent.; correct measurement
 of all kinds of Lumber, Saw Logs, Cisterns, Tanks, Gran-
 aries, Bins, Wagon Beds, Corn Cribbs; a Time, Wages
 and many other valuable tables.

The second part is a practical arithmetic, and embodies
 a simple mathematical principle which enables any one
 familiar with the fundamental rules to become a light-
 ning calculator; and by which over two-thirds of the fig-
 ures and labor required by the ordinary methods, and
 fractions with their intricacies, are entirely avoided.

The work is nicely printed on fine tinted paper, is well
 and elegantly bound in pocket-book shape and is accom-
 panied by a Silicate Slate, Memorandum and Pocket
 papers. It is by far the most complete, comprehensive
 and convenient pocket manual ever published.

Price, bound in Fine English Cloth, \$1.00.

Sent direct from the Eastern publisher, postpaid, on
 receipt of price, by P. O. order, registered letter, or
 receipted by express. Address

DEWEY & CO., San Francisco.

Continued from page 293.

Twenty carloads of ore were delivered at the Eureka Consolidated works yesterday.

HOOSAC.—We are pleased to announce that the efforts of Billy Wernuth to place the Hoosac property in the New York market have been crowned with success. Deeds, conveying the property to the Hoosac gold and silver mining company of New York, were yesterday filed in the office of the County Recorder. We have not been favored with the figures, but take it for granted that the price paid by the New York company was something handsome, as the Hoosac, in days gone by, was one of the most productive and best paying mines in this portion of the State. The reduction works of the company are also extensive and first-class. It will look like old times to see the Hoosac once more in full blast.

WHITE PINE DISTRICT.

LOOKING UP.—White Pine News, May 5: Mining matters in this district are improving. In the fore part of the week Superintendent Fulton put a force of men to work on his company's mines, on Treasure hill—the Ward Beecher Consolidated. He informs us that his company intends to thoroughly prospect their mines the coming summer. Colonel Tyson, of the '76, came up from San Francisco, and the company with intention to immediately commence the erection of a furnace for the reduction of their ores. These new enterprises, together with the old ones—the Eberhardt and Aurora and the Stafford—ought to improve the business of this district greatly the coming season. A very important strike has been made in the west incline of the Jennie A. This had been expected by Superintendent Ford before he left for the bay. Large ore body is now being opened out in this incline, which no longer leaves a doubt as to the true merits of the mine.

Arizona.

HUMBURG DISTRICT.—Arizona Enterprise, May 3: Upon the Tip-Top work is being vigorously carried on. The north shaft is now down 95 feet and the south shaft about 70. The face of the tunnel is in good ore, showing a vein of two and a half feet of antimonial ore and staphanite. There are between 200 and 300 tons of unassorted ore on the dump. About 20 sacks of the first-class ore, which goes over \$300 to the ton, have been sorted out. An average assay of the rock left, after assorting out the first-class ore, went \$221. There are 10 hands now working on the tunnel, taking out ore. This is rapidly rising into prominence as one of the very best mines in the country. The gangue of the mine is spar in formation of granite. Upon the Nevada, which is a small vein, some very high grade ore has been taken out. Three tons from this mine yielded \$670 to the ton. It is situated on Cottonwood creek, about three-quarters of a mile above the Tip-Top. Messrs. Huff & Park are working upon the Silver Star, which has been recently located, and are getting out some very high-grade ore. C. A. Carpenter located, last Saturday, the Jefferson and Robert Lee. The former is a very large ledge, and Mr. Carpenter had two high-grade ore, but the latter is of two different classes of ore from this mine. One sample went \$28.33 in silver and \$180.45 in gold, which is good enough for surface rock on a large vein. Upon the Rescue the shaft is now down 30 feet, showing an ore body of from two and a half to three feet in width, of good chloride ore.

RICH PLACERS.—Arizona Miner, May 5: We are informed by S. Lount, Esq., that near the Stone ranch, on Black Canyon road, several Mexicans are at work on a bar, and are making from \$1.50 to \$3 per day, and are compelled to carry their dirt, from which they wash the gold, about one-quarter of a mile. We are assured by Mr. Lount that the bar where these Mexicans are at work will afford employment for 50 men, six months, with rockers and other means of washing out the precious metal, and that good wages would certainly be the result. The last work done on the bar by white men was several years since, when they were making \$10 per day to the man, and only abandoned the work on account of the hostility at that time of the Apaches.

BIG STRIKE IN BRADSHAW.—We are informed by Mr. C. A. Luke, who is putting up a fine 10-stamp mill, in the basin at Bradshaw mountain, that his workmen have discovered, in the immediate vicinity, where he is erecting his mill, a large body of very rich silver ore. So far, it seems that they have found a well-defined lead, but rather a body of ore, where hundreds of tons can be procured with little expense. The ore is of a blackish color and has been passed over by miners and others, time and time again, without the slightest idea that it contained silver or any other precious metals, it being such a huge mass that no person would, for a moment, give it even a thought. We believe Mr. Luke has made a good investment in the mill, which he is putting up, and the finding of such large quantities of rich ore adjacent thereto is certainly very fortunate.

CEDAR VALLEY DISTRICT is looking up, and quite a number of miners are at work on the different ledges.

The Independence mine, on the Arnold ledge, which is considered one of the best mines in Mojave county, has been bonded.

MOJAVE COUNTY is fast filling up with good miners, and many new discoveries are being made.

PECK DISTRICT.—The Josephine, which was discovered and located a few days since, by E. Gobin and Thomas Holland, is said to be not only extraordinarily rich in silver, but also carries a large quantity of free gold. The Treasure Vault is also one of the latest discoveries, and shows well on the surface. Several loads of rich ore from the Salvadora mine passed through town on its way to the Arizona mill, which, the site of the old Bully Buena mill, for the purpose of working ores from different leads in that vicinity, started in to work on Friday last.

BLACK WARRIOR MILL.—The mill, which was purchased by Mr. S. M. Wessels, in San Francisco, for the Black Warrior mine, has arrived at Ehrenberg, and is there held by the steamboat company for freight.

RICH DISCOVERIES.—A Mexican recently discovered a lead about 50 miles east of Prescott, and located the same for himself and Mr. John G. Campbell. Assays have been made in the different assay offices in this village of the ordinary ore picked up on the surface of the lead, and each agree in putting the value at \$1,500 per ton. The lead is about six feet wide, and is traceable on top the ground for about a mile. The theme of this new discovery is the Mexican. Several parties have been out to this new discovery and made locations, and all agree that it is a "big thing."

DRY WASHING.—Fred Valentine, who has been engaged in dry washing in the Santa Maria country, for over a year, arrived from the placers last night. Mr. Valentine informs us that his new dry washer works to a charm, with the exception of the fire-place, which was too small and did not draw sufficiently to make a heat sufficient to wash the dirt containing gold. During a run of two hours he took out \$11.50. The machine saves 100% in labor. Where six men were formerly required, it now takes but three. Mr. Valentine has had greater experience in dry washing than any man in the Territory, having been engaged for a long time in the mines at the Picacho, on the Gila, and the mines east of Ehrenberg. He represents about 20 Americans as being at work in the placers, at the Santa Maria mines, and that they are all making fair wages. These mines are about 60 miles from Prescott and 20 from Greenwood. Mr. Valentine also informs us that Indian signs are everywhere to be seen.

Idaho.

MINING NOTES.—Idaho Avalanche, May 5: There is no change to record in connection with the mining outlook

here. The prospects for the season are not regarded by any means as unfavorable. As soon as the questions connected with the status and ownership of various mining properties in this vicinity are settled, men will be found who will go to work and aid in an honest development of the mines thus set free.

GOLDEN CHARIOT.—Work is being vigorously prosecuted and everything in and about the mine continues to wear the most cheering complexion. The work of drifting south on the Crane & Briggs ledge from the point of intersection with the cross-drift from the 6th Chariot has resulted in the opening up of a splendid body of high-grade ore, which improves in quality as the operations go forward. The vein grows wider and richer and promises to be of itself a bonanza of magnificent dimensions. The slopes are yielding well, particularly those going south from the winze between the 6th and 7th levels.

The excitement of the past few days has been the rich strike at the Belle Peck, which the workmen encountered on Monday morning. It is a genuine bonanza and no mistake, and comes to light just where Mr. Peck the owner of the mine promised and expected it would. The new development is about 800 feet below the surface, and 110 feet south from the shaft in the direction of the Poorman. Mr. Peck has had to have a large amount of money expended and a great deal of labor performed in order to reach the ledge at this point. Rock is now being taken out at a lively rate and there will be a crushing in a few weeks. This rich strike comes in the "nick of time," and is bound to wield an influence for the better on the welfare of the camp.

This prospects of the Empire as well as the Poorman loom up by the discovery of the rich lead in the Peck, and the Empire company will probably hesitate no longer in prosecuting an enterprise that is morally certain to yield them millions of wealth, and at a comparatively trifling outlay. The ledge at the Empire and in the vicinity is more liberally streaked with gold and carries a heavier proportion of the precious metal than is found in any other ledge in the country.

Work has been actively resumed in the Potosi, the surplus water has been removed and the mine is looking first-rate throughout. There is plenty of rock which will crush all the way from \$40 to \$100 to the ton, and a good season's work is anticipated.

Montana.

DEXTER.—Butte Miner, May 4: Nothing of special interest to report from the Dexter mill this week, the managers still supplying the works with low grade ore. A full set of new stamps and dies are soon to be put in, when a higher class of ore will be furnished, the present condition of the old ones being unfit for use in crushing ores of great value. The shipment of the week was four bars, valued at about \$4,000.

The prospecting that has recently been going ahead on the Uinta ledge claim gives assurance of this being one of the best leads in this camp, the last ore taken from the bottom of the shaft now being worked assays 697.70 ounces per ton in silver, besides showing free gold.

There are 32 or 33 men now employed on the Lexington ledge and five or six on the Copper ledge, the property of A. J. Davis. The Lexington shaft—the deepest one—is down 110 feet, and the water is coming in pretty freely. In fact hoisting works will have to be erected before sinking can be resumed.

One of the new plans was put in motion at the Davis last week and is now running and doing good work, increasing the capacity of the works about one-third and giving the battery nearly full run. The other plan, making five in all, and another settler will be ready to put in in about three or four weeks, when the amalgamating facilities will be increased to all the battery can possibly crush. The mill is now crushing about 10 tons per day.

PONY MINES.—Madisonian, May 3: We found Mallory's 10-stamp mill running night and day. The mill was running on custom ore, and, from all appearances, pretty good ore at the battery nearly full run. The other plan, making five in all, and another settler will be ready to put in in about three or four weeks, when the amalgamating facilities will be increased to all the battery can possibly crush. The mill is now crushing about 10 tons per day.

Mr. Gornley is preparing timbers for the erection of a quartz mill early in the season, and it is safe to estimate that before fall the number of stamps now in operation will be doubled, and there is ore enough for them all.

PATENTS AND INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

(FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.)

FOR WEEK ENDING MAY 1ST, 1877.

190,146. KEY FASTENER.—L. W. Kennedy, Oakland, Cal.
190,210. HARROW.—J. B. Greene, Elliott, Cal.
190,217. REVOLVING ORE ROASTER.—J. Howell, Benton, Cal.

190,224. BUNG AND BUNG INSERTER.—W. Kromer, S. F.
190,225. WINDOW SASHES.—L. Landecker, San Luis Obispo, Cal.
190,234. DEVICE FOR ELEVATING EARTH.—G. E. Milliken, Los Angeles, Cal.

190,244. URINALS FOR INVALIDS.—R. H. Olmstead, Napa City, Cal.

190,245. VALVE MOTION AND CUT-OFF.—Eugene O'Neill, Oakland, Cal.

190,257. MEANS FOR UTILIZING EXHAUST STEAM.—W. H. Thomas, Wilmington, Cal.

The patents are not ready for delivery by the Patent Office until several days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

WINDOW SASH.—Lazare Landecker, San Luis Obispo. The object of this invention is to provide such a construction of window sashes that the panes of glass can be secured in place and removed and replaced whenever desired by any ordinary person, thus avoiding the necessity of employing a glazier to do the work. The improvement also allows the inventor to construct window sashes so that they can be taken apart and compactly packed for shipping after the manner known in commerce as "knock down" articles. The wood work can thus be packed in one package and the glass in another, saving expense not only in the cost of shipping, but also reducing the liability of breaking the glass. The invention consists therefore in constructing the mullions of the sash with simple grooves in which the edges of the panes of glass fit, and in providing slots in the edges of the

outside rails of the sash opposite said grooves, through which the panes of glass can be slid into place in the manner of a drawer. A filling is thus secured in the slot in the sash rail so as to prevent the glass from coming out. In order to render the removal and replacing of the panes more convenient and to permit the sash to be "knocked down" for shipping, the mullions are made in sections so that they can be taken to pieces.

DEVICE FOR ELEVATING EARTH.—Geo. Milliken, Los Angeles. This invention relates to that class of machines which are intended to elevate earth, sand or any other material, and which consists of an endless belt or band passing over pulleys and provided with suitable elevating buckets. The improvement consists in a novel combination of an elevator with suitable operating gearing and shafts and a movable or adjustable crane, whereby the elevator can be shifted so as to work at any desired point within its reach without removing or altering the stand or support. The operation of the device is very simple, as it is only necessary to set it so that the lower end of the elevator belt will rest upon some part of the bank to be excavated, and set it in motion to raise the earth which may either be deposited into carts or upon an endless carrying belt by which it will be removed to any distant parts. The elevator belt may be moved from time to time to new points, and by swinging the arm of the crane around, work may be done in a large circle without changing the locality of the machine.

VALVE MOTION AND CUT-OFF FOR STEAM ENGINES.—Eugene O'Neill, S. F. This is a combination of mechanism for opening and closing steam and exhaust valves in a steam engine; the opening being effected gradually, until the valve has started from its seat, and completed rapidly, while the closing of the valve is controlled by the closing of a cam or cams, which are made to release the valve and allow it to drop, at any desired point in the stroke of the engine; the whole mechanism forming what is known as a variable cut-off. It consists in combination with the vertically acting valve stem, of a horizontally moving bar having a peculiarly shaped curve formed upon its upper side, whereby the lifting of the valve is effected; also in the employment of a cam or cams in combination with the stem so actuated that at any desired point in the piston stroke it will release the valve from the action of the elevating devices and allow it to fall and cut off any further accession of steam to the cylinder.

The Justice Mine.

The annual meeting of the Justice mining company was held on Monday last, and the old management re-elected.—Messrs. Schultz, Von Bargen, Sherwood, Phelan and Richard.

So many conflicting statements have been in circulation relative to this company, that the Directors concluded to give a full exposition of previous managements, as well as the present; and from the President's report we extract the following:

"The Trustees for the past year found the company laboring under financial difficulties of no small dimensions—its credit impaired, by reason of an immense debt, and the value of the company's property misrepresented by parties hostile to the management. To successfully carry the company through its financial troubles, without an appeal to the individual stockholders, was the intention of the new Board, themselves the actual owners of over one-half of the capital stock. That they would have succeeded, there is no doubt, but for unforeseen difficulties thrown in their way by parties who, for their own private ends, were constantly laboring to depress the market value of the company's stock and misrepresent the worth of its property. The Board finally decided to call on the individual stockholders for assistance to sustain the credit of the company, and assessment No. 19 was levied and collected, the total amount of which was \$525,000. This was the only assessment levied by the Board during the fiscal year, and the entire amount was applied in the reduction of the debt incurred by our predecessors in office. While engaged in arranging the affairs of the company in this city, the work of the mine was being pressed with all vigor, and so well were their efforts rewarded, that in less than six months the mine was changed from a non-producing to an ore-producing one, and has been steadily improving, until it ranks third among the ore-producing mines of the Comstock. All ores extracted by the company have been crushed by custom mills in close proximity to the mine, the management deeming it prudent to delay incurring a large debt for the purchase and erection of mills for the company's account until the continuance of the ore body had been fully demonstrated. This is nearly accomplished, and a short time only is required to demonstrate the fact that the Justice mine is a permanent one, and that the yield of ore will be measurably increased, thus enabling the future managers to place the company among the list of dividend-paying mines of the great Comstock lode."

The Superintendent reports that the total number of tons of ore extracted for the year just ended is 80,563½. No surplus of ore was carried over from the preceding year. During the same space of time there has been reduced at the various mills employed by the company, 78,338

tons, yielding bullion to the amount of \$1,755,411.37. This yield is about 80% of the assay valuation of the ore—no deduction having been made for wet ore. Now on hand at the mills and in ore house, 2,220 tons, valued at \$45,000. The entire amount of this ore has been extracted from the 400, 500, 600, 700, 750, 800 and 1,000-foot levels. The most prolific of which have been the 400 and 600-foot levels, these having proved more lucrative than levels below, they being comparatively new levels. On the bottom of the 700-foot level, and for a distance of 380 feet, a body of ore is developed, pierced midway by a winze running through a continuous and broken ore body to the 800-foot level. The present face of the north lateral drift shows a body of fair average milling ore, about 10 feet in width. The company's vein is incased within a fissure, ranging from 300 to 450 feet, with spurs of ore found in all directions, interspersed with clay seams and walls running a certain distance and then entirely disappearing. Invariably, these spurs of ore are small and contain a large percentage of silica, hence the great expense of mining.

The report of the Secretary showed the year's receipts to have been, \$2,617,137, of which \$1,755,411 was the gross product of the mine. They spent \$543,434 for salaries and wages; \$43,000 for hardware; \$63,221 for lumber; \$9,320 for wood; \$62,745 for interest; \$925,171 for reduction of ore, etc. The discount on bullion was \$127,723. An item of \$600,000 called "bills payable," in the disbursements, the Secretary explained included a debt of \$480,000 due for title and equitable rights in a certain quantity of Woodville stock held in trust for the company. Mr. Robinson wanted to know if the assessment of \$525,000, levied September 14, 1876, did not put the company square with the world. The Secretary replied that at that time the company owed about \$680,000, and no one of the management asserted that the collection of the assessment would make all claims good. He did say that it was hoped and expected at the time that the ore would pan out sufficiently well to make up the difference. But for the first six months of the fiscal year the mine ran behind in its expense account, while for the last six months there had been a gain of \$35,000. In reply to a question of economy in salaries and in the reduction of ore, the Secretary stated that as for his own salary it was \$150 per month; that up to last month \$12 per ton had been paid for crushing ore, while for the last month only \$11 had been paid. He did not know that it could be done for nine dollars, as suggested by one stockholder, or even for \$10, as suggested by another.

Confidence Gold Mine.

EDITORS PRESS.—With the mining community generally but little is known of the Confidence quartz mining property, in Fresno county. Until recently it was held by its actual discoverers, who, I might add, were simple, honest, hard workingmen, but inexperienced as to the true rudiments of mining to secure success. I visited the property on the 8th of last January, examined it and fully satisfied myself that it was not only a good but a most valuable property if properly engineered. This I communicated to my friends, chiefly Merced City men, who came up and purchased the entire property. The main shaft is in a three-foot vein the entire distance, except in shaft's bottom, where it has widened to four feet, all first-class ore. Our last crushing netted us \$154.22 per ton. This was rock taken out in our last sinking. We have a first-class water privilege for free milling power, and by last of June hope to have our new mill running in full blast. This section is in its infancy as pertains mining, but I predict the day is not distant when we shall see more enterprising mining men searching Mother Earth to rob her of her treasures than in the past. Our property has been valued by some gentlemen at \$500,000, but its actual value at present cannot be fully estimated. Up to the time of which I am writing no mine can possibly show a better prospectus than can the Confidence. Respectfully,

J. F. Cox, Supt.
Fresno Co., Cal., April 30th, 1877.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

HEMME AND LONG PLANO MANUFACTURING Co.—May 7th. Capital stock, \$100,000. Directors—A. J. Hemme, J. B. Frisbie, S. H. Long and W. C. Hemme.
PACIFIC PLUMBING M. & C. Co.—May 9th. Location—Hermosillo district, Sonora, Mexico. Capital stock, \$2,400,000. Directors—J. J. Mullen, F. T. Gilbert, L. Lanzwert, J. N. Thorne and O. Smith.

Sinking the Chollar-Hale & Norcross combination shaft is going forward at the rate of three feet per day, which considering the immense size of the shaft, is as good work as has ever been done in any mine on the Comstock.

"CRAZY HORSE" has surrendered to General Crook with 1,300 Indians, about 3,500 ponies and all the arms.

The working force at the Jefferson mine, Nev., has been reduced, but the mine has not shut down as reported.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

New Style of Portable Engine.

One of the new things in the way of machine making, which our readers will be interested to hear of, has been brought about by Mr. H. W. Rice, who is well-known as a manufacturer of portable engines. Not long ago Mr. Rice moved his works from Haywards, Alameda county, to this city and erected a commodious shop on Bluxome street, near the freight depot of the C. P. R. R., corner Fourth and Townsend. During a recent visit to the shop we saw upwards of 25 engines, straw-burners, wood and coal-burning, portable and stationary engines in various stages of construction. The most attractive looking engine we saw was a small-sized portable threshing engine with an entirely new form of boiler. Mr. Michener, foreman, says that this boiler has more heating surface according to its weight than any other portable engine of its size. The boiler is 36 inches in diameter, and has 28 tubes two and a half inches in diameter and six feet long, which would give 140 feet heating surface. There is a large ash pan underneath the fire. In the large size straw-burning engine the ashes fall on the bottom of the main flue, which allows a limited space, but in this new style of boiler about one-fourth of the lower side of the main flue is cut away its whole length, also about one-third of the length of the shell of boiler under the fire end. The ash pan is riveted under this portion of the boiler. This cutting away of the main flue allows it to come down so as to leave room for an additional row of tubes on top of the flue. This makes the boiler much lighter and equally as strong. These engines are all fitted with Michener's hollow valve, which Mr. Rice claims to be very valuable and economical. Steam is admitted to the cylinder at the end. The steam chest is very long. The space from the valve seat into the cylinder is only seven-eighths of an inch, and the length of port is the same as the diameter of the cylinder, which is (six inches). The cylinder stroke is 12 inches. The engine is on a bed plate.

The manufacturer tells us that great care is taken to make the boiler as strong as possible. It may be believed that the less holes in a steam boiler the better. Working on this idea, the glass water gauge, safety valve, spring balance, whistle, blower and steam gauge are put into the boiler and connected to one pipe. This requires only two holes to be made in the boiler. Both sides of the water space are connected by a pipe under the boiler, in which is placed the blow-off cock and a union connection. The fly-wheels of the engine are 36 inches in diameter and seven inches face, and made crowning, so that the belt will not blow off in windy weather. The engine is fitted with a Gardner governor. The wheels and pole are painted a very appropriate straw color, with black stripes; the boiler and smoke-stack black, and the engine is a bright red. The total weight is about 4,500 pounds. It is claimed to excellently adapted for hill work. It sets low on wheels, with wide tires, and will ride well on side-hills without danger of upsetting. It will run a 36-inch separator, and burn any kind of fuel desired by changing grate bars.

CHEROKEE.—A visit to this famous mining town a week or two since—the first for three or four years—shows but little change in the place, except in the way of washing out huge places in the face of Sugar Loaf hill and the butt end of Table mountain. The face of the claim seen from the valley, is that of Sugar Loaf. The much larger face washed out of Table mountain faces more to the east, and is visible from the valley. A narrow strip now divides what we suppose to be the upper and lower claims. Hydraulic giants are playing upon it, however, and giant powder is tearing it to pieces, and soon the operations of the Cherokee mining company will show a continuous line of washed gravel for a mile or more in length, and varying from a few rods to half a mile in width. Winding away down the ravines, to the dump in Messilla valley, extends the flume of the company, with their under-currents and other devices for saving the gold. The water, brought on to the claim by huge pipes and under a heavy pressure, is hurled against the bank with irresistible force and power. A large force of men are occupied during the day, working from 7 A. M. until 6 P. M., when a night shift is put on to attend the flume and the hydraulic chiefs, and the water is thus made to do constant service. Those who remember the amount of debris sent into the valley, and the hill whereon stood the store and hotel of Moore & McDaniels, can form some idea of the amount of earth worked out by this company. What will be accomplished in the future can only be estimated by the size of Sugar Loaf and Table mountains, and adjacent hills.—*Butte Record.*

The New York Gold Exchange, with the close of business on the 20th ult. ceased to exist. The business of the gold room will hereafter be under the charge of the New York Stock Exchange, and will be carried on in all particulars as now. At the time of dissolution there were \$123,000 in the treasury.

A few days ago the employees of the Virginia & Truckee railroad, between Virginia and Gold Hill, were notified of a reduction of wages from \$3 to \$2.50 per day. The Labor Union is taking the matter in hand, and have announced their intention of striking if the reduction is carried into effect.

General News Items.

ADMIRAL POPOFF will take command of the Russian armament in the Black sea.

At a recent meeting of American glass manufacturers, prices were advanced five per cent.

The largest carpet-mills in the United States, those of Dobson, at Schuylkill Falls, will close, thus throwing out of work some 1,400 hands.

ONLY about half of the canneries on the Lower Columbia are in operation, owing to the light run of salmon. The warm weather will soon cause a rise in the river, when the fish will commence running in great numbers.

The financial earnings of the Central Pacific railroad company for the first four months of this year, amount to \$4,734,600. This is an increase of \$111,000 over the corresponding months of last year.

A SPECIAL to the Union from Tucson, Arizona, says: Indian agent Clum left Hot Springs, May 1st, with 423 Indians for San Carlos. The military authorities of New Mexico and Clum, agree that a complete removal has been made.

The Grand Jury, in relation to the recent post office accident in New York, find nobody individually responsible, but charge negligence, inefficiency and inexperience on the Supervising Inspector and assistants, and recommend a thorough inspection of the whole building by experts.

The Archbishop of Quito was poisoned on Good Friday, at Panama, while saying mass, by means of strychnine introduced into the wine in the ceremony. There was great excitement and indignation over the sacrilege. The perpetrators have not been discovered.

EX-PRESIDENT GRANT, on his arrival in London, will have a special audience with Queen Victoria and be the guest of Disraeli and other eminent men. It is said that in deference to the high office he has filled, the Queen will pay him a visit.

The Postoffice Department has contracted with Clarence Van Tassel, of Dakota, for a mail service from Fort Pierre, on the Missouri river, to Deadwood, 180 miles, tri-weekly, until September 30th, at the rate of \$9,919 per annum. It is established in compliance with a general demand, to give the people of the Black Hills country direct communication with Yankton.

Academy of Sciences.

The regular meeting of the California Academy of Sciences was held on Monday evening last.

Professor Davidson read a paper on "Breakwaters and Harbor and River Improvements in Europe and Asia."

Dr. George Bennett, of Sydney, New South Wales, was introduced to the Academy, and called attention to a new beetle discovered in New Guinea, and other interesting points.

Prof. Davidson read a short essay on A. F. Goddard's objections to the treatment extended to his theories of the transit of Vulcan, maintaining that they were baseless.

The following resolution, prepared by Henry Edwards, Esq., was read and adopted (Dr. Kellogg in the Chair *pro tem*):

WHEREAS, Under the laws of the State establishing the University of California, in addition to certain State officers, who are made Regents of said University *ex officio*, the President of the State Agricultural Society and the President of the Mechanics' Institute, for the time being, are also made Regents, by virtue of their official positions in said societies; that through in-advertence or otherwise, the California Academy of Sciences, an independent organization, founded before either of the foregoing, and whose objects and transactions cause it to be more nearly related to the University than the other societies named herein, though honorably recognized by the leading scientists and by all of the prominent scientific societies and institutions throughout the world, has no formal recognition by the State or representation in said Board of Regents; and

WHEREAS, Said Academy cannot be legally and authoritatively placed in the same position as the said Mechanics' Institute and State Agricultural Society without an amendment of the organic law upon which said University rests; therefore,

Resolved, That the California Academy of Sciences respectfully, but urgently, requests his Excellency, Governor William Irwin, to appoint Professor George Davidson, President of the Academy, as a member of the Board of Regents, to fill the vacancy created by the death of the late Hon. John B. Felton, and unhesitatingly recommend said appointment as being honorably just to the Academy of Sciences, and creditable alike to His Excellency and to Professor Davidson, whose education, ability and enthusiasm make him an eminently fit man for the place and for the interests of the University.

A VALUABLE MINING BOOK.

BY J. S. PHILLIPS.

The Explorers', Miners and Metallurgists' Companion, 682 pages, 83 illustrations. Second Edition. A California publication.

OPINIONS OF THE PRESS.

The book is exactly calculated to suit the views and meet the requirements of those for whom it has been written.—*London Mining Journal.*

The most practical and comprehensive work on mining subjects extant, and valuable book of reference.—*Mining and Scientific Press, San Francisco.*

We know of no work on these subjects in the English language at once so comprehensive, practical and intelligible.—*S. F. Golden Era.*

He has rendered to the leading industry of the coast a valuable service—has furnished the millman and miner a safe and much needed practical guide.—*Overland Monthly.*

This book, which treats in an intelligent and practical way on almost every topic connected with mining pursuits, should be in the hands of every millman, metallurgist, prospector and miner on the Pacific coast. Even the capitalist, and, in fact, every person already engaged in, or likely to become interested in the business of mining, will find in this comprehensive work an amount of information that they cannot afford to dispense with.—*S. F. Commercial Herald.*

This book is free from trash, and solid throughout; all its matter is intelligible to men of ordinary education, and all of it is valuable to miners.—*S. F. Daily Alta.*

In the several sections the work is eminently practical. Is very comprehensive, and contains a great deal of useful information which cannot be obtained from the previous books that have been written on these subjects.—*S. F. Daily Examiner.*

It affords a vast quantity of information as to the appearance and value of different ores.—*S. F. News Letter.*

It is the best single English treatise we know for the use of prospectors and practical miners.—*The Engineering and Mining Journal, New York.*

Sold by Dewey & Co., at this office. Price \$10.50.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. TITIAN—San Francisco.
B. W. CROWLEY—Amador, Placer, Calaveras and Tuolumne counties.
G. W. McGREW—United States.
A. C. KNOX—Plumas, Sierra, Lassen, Placer and Nevada counties.
C. N. WEST—Santa Cruz, Monterey and San Benito counties.
A. C. CHAMBER—Sonoma, Marin and Mendocino counties.
A. U. STRONG—Lake, Napa and Solano counties.
W. D. WHITE—San Bernardino and Los Angeles counties.
ED. T. PLANK—Dakota Territory (Black Hills).
JOSEPH DIMMICK—Mendocino county.

THE GRAND PACIFIC HOTEL, Chicago, with its central position and railroads branching off in every direction, is naturally a point to which travellers from all parts of the country are apt to come more or less frequently. Being there, a hotel is a necessity. A first-class one in every respect will be found in the "Grand Pacific," which is the temporary home for our off-hand Western folks who want to go to the best place the first time. The hotel is a handsome one and is fitted up in fine style with all the modern conveniences. It is centrally located, keeps a first-class table with the best market affords at all times and seasons, and the proprietors know how to make their guests feel at home.

Mining and Other Companies.

Booth Gold Mining Company.—Location

of works, Auburn, Placer county, California. Notice is hereby given that at a meeting of the Board of Directors, held on the thirtieth day of April, 1877, an assessment (No. 2) of five cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, No. 320 California Street, Room No. 3, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the fourth day of June, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on the twenty-fifth day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Directors, GEO. R. SPINNEY, Sec'y.

Office, 320 California St., Room 5, San Francisco, Cal.

California and Arizona Mining Company.—

Location of principal place of business, 507 Montgomery Street, San Francisco, California. Location of works, Mohave County, Territory of Arizona.

Notice is hereby given that at a meeting of the Board of Directors, held on the third day of April, 1877, an assessment (No. 2) of two cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin to the Secretary, at the office of the company, 507 Montgomery Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the thirtieth day of May, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the fourth day of June, 1877, to pay the delinquent assessment, together with the costs of advertising and expenses of sale. By order of the Board of Directors, T. E. JEWELL, Secretary.

Office, 507 Montgomery Street, San Francisco, California.

California Fruit Growing Association.—

Location of principal place of business, San Francisco, California. Location of property, El Dorado county, Cal.

Notice is hereby given that at a meeting of the Board of Directors, held on the 14th day of April, 1877, an assessment No. 4, of \$2.00 per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary at the office of the company, 331 Sansome Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 21st day of May, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday the 9th day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, HORACE JONES, Secretary.

Office, 331 Sansome Street, San Francisco, Cal.

Consolidated Bonanza Silver Mining Co.—

Principal place of business San Francisco, California. Location of works in Eagle and Washoe Valley Mining District, Ormsby county, State of Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 19th day of April, 1877, an assessment No. 1, of 10 cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary at the office of the company, No. 19 First Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on Tuesday the 23rd day of May, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the 19th day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, WM. MARTIN, Secretary.

Office No. 19 First Street, San Francisco, Cal.

Dolores Consolidated Mining Company.—

Location of principal place of business, San Francisco, California. Location of works, Dolores Mining District, Esmeralda County, Nevada.

Notice.—There are delinquent upon the following described stock, on account of assessment (No. 1) levied on the seventeenth day of February, 1877, the several amounts set opposite the names of the respective shareholders, as follows:

Name.	No. Certificate.	No. Shares.	Amount.
Blasdel, H. G., Trustee	16	10,000	\$1,000 00
Blasdel, H. G., Trustee	17	5,000	500 00
Blasdel, H. G., Trustee	18	5,000	500 00
Blasdel, H. G., Trustee	19	5,000	500 00
Drexler & Co., Trustee	8	2,500	250 00
Fraser & Co., Trustee	9	10,000	1,000 00
Keene, J. R., Trustee	7	10,000	1,000 00
Talbot, W. C.	3	100	10 00

And in accordance with law and an order of the Board of Directors, made on the seventeenth day of February, 1877, so many shares of each parcel of such stock as may be necessary, will be sold at public auction at the office of said company, on Monday, the sixteenth day of April, 1877, at the hour of two o'clock, P. M., of said day, to pay said delinquent assessments thereon, together with costs of advertising and expenses of the sale.

J. W. CLARK, Secretary.
Office, 418 California street, San Francisco, California.

Empire Mining Company.—Location of

principal place of business, San Francisco, California. Location of works, War Eagle Mountain, Owyhee County, Idaho Territory.

Notice is hereby given that at a meeting of the Board of Directors, held on the twenty-sixth day of April, 1877, an assessment No. 13, of \$1 (one dollar) per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company, No. 330 Pine Street, Room No. 5, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the thirtieth day of May, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the eighteenth day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, W. H. MCCLINTOCK, Sec'y.

Office, 330 Pine Street, Room No. 5, San Francisco, Cal.

Excelsior Silver Mining Company.—Prin-

cipal place of business, San Francisco, Cal. Location of works, Potosi District, Lincoln County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the twenty-fourth day of April, 1877, an assessment of ten cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold and silver coin, to the Secretary, at the office of the company, 306 Post Street.

Any stock upon which this assessment shall remain unpaid on the thirty-fifth day of May, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the eighteenth day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, A. KOLLMYER, Secretary.

Office, 306 Post Street, San Francisco, Cal.

The Ingersoll Rock Drill

Is Extensively Used in the East and

TAKES THE PLACE OF ALL OTHERS.

Wherever introduced, because it can be run with less
power, labor and repairs, and do more work than any
other Drill in the market. It has but few parts, is easily
handled, being light, and has AUTOMATIC FEED, which
saves labor. WE ASK FOR TRIAL AGAINST ANY
COMPETITOR. For particular information regarding
Drills or Air Compressors, send for circular to

J. B. REYNOLDS,
320 Sansome Street
(Room 10.)

THE O'HARRA CHLORIDIZING FURNACE

Guaranteed to Chloridize from 85 to 95 per cent. of any
gold or silver ores that are not more profitable for smelt-
ing. Will also desulphurize ores and put them in proper
shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this
Process:

Two cords of wood at \$6.....	\$12.00
Two firemen at \$4.....	8.00
1,500 lbs of salt at 1¢.....	22.50
Wear of shoes and power.....	1.50
Cost for 15 tons.....	\$44.00
Cost for one ton.....	2.93 1/3

In a furnace of three or four times this capacity the
cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Con-
solidated Co's mines, in the Peavine District. For
further information, apply to

D. J. O'HARRA,
Reno, Nevada.

Sole Manufacturers of

BRUCKNER'S PATENT
REVOLVING FURNACE,
For Chloridizing, Desulphurizing and
Roasting Ores.

—ALSO—

STEAM ENGINES, SAWMILLS, SHAFTING, GEAR-
ING AND MINING MACHINERY.

Send for our Illustrated catalogue.

H. W. RICE,

Manufacturer of

The Rice Patent Straw-Burning Engines.

Portable and small engines for Pumping, Grinding, Saw-
ing and all purposes. These engines burn less fuel than any
engines in use. Wood-Burning Engines changed to Straw-
Burners. Saw-mill and Flour-mill Engines. Second-hand
portable engines and boilers in good repair, cheaper than at
any other place in the State. New boilers made to order,
and repairs in the city or country done promptly. Repairs
made on wood-working and fine machinery. Threshers and
agricultural machinery made and repaired. ALL WORK
WARRANTED. Office and works, No. 56 Bluxome Street,
near Fifth, San Francisco, Cal.

LEVI STRAUSS & CO.,

Patent Riveted

Clothing,

14 & 16 Battery St.,
San Francisco.

These goods are specially
adapted for the use of
FARMERS, MECHANICS,
MINERS, and WORKING
MEN in general. They
are manufactured of the
Best Material, and in a
Superior Manner. A trial
will convince everybody of
this fact.

Patented May 12, 1873.

PATENTED
**CAST STEEL SHOES
AND DIES.**

Guaranteed Cheaper than the Best Iron.

IMPORTANT NOTICE.

Reduction in Price from 16 Cents
to 12 Cents Per Pound.

Owing to our largely increased business, the present low price of Iron from which our Steel is manufactured, and the improved facilities for casting and forging, we take great pleasure in announcing that from and after this date we will supply our IMPROVED CAST AND FORGED STEEL SHOES AND DIES FOR QUARTZ MILLS at twelve cents per pound, delivered at San Francisco or Sacramento, instead of sixteen cents, as heretofore.

We also furnish Steel Plates for Blake and other Ore Crushers, Steel Gut Gearing, etc., for Mills and Hoisting Works, Steel Pan Shoes, Battery Cams and Tappets, etc., etc.

Address all orders, with dimensions or drawings, to

\$1,000 Challenge Ore Feeder,

AWARDED FIRST PREMIUM

At the Tenth Industrial Fair of the Mechanics' Institute.

It may be considered as now fully demonstrated, by careful and long-continued experimentation, that the plan upon which a perfect ore feeder must be constructed is that of the carrier, and not that of the shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply dropped. Spasmodic or jerky contrivances will not answer the purpose.

REFERENCES.

A letter received from the Julian Mill, Newcastle, says of the Carrier Feeder: "It is the most perfect Feeder we have ever seen; don't see how any mill can do without them." A letter from Mr. C. C. Belding, of Amador County, speaks in the highest terms of them. Two of the machines were shipped to the Sunkers Hill Mill, also Gover Mill, Amador County. Mr. Stevenson, of Boston Mill, Gold Hill, Nevada, says they are the best Feeder he has ever seen. Soulsby Mill, Tuolumne County. California Company, Nevada City. Omaha Gold Mining Company, Grass Valley. St. Patrick Mill, Placer County.

\$1,000 CHALLENGE.

Backward in Coming Forward.

C. P. Stanford Fails to Come to Time on the Challenge of \$1,000 to Test the Merits of His Ore Feeder as Against Mine. The Challenge is Still Open to Him or any one else. GENTLEMEN, Put up or Shut up.

A letter has been received from the Crescent mine, Plumas County, in which it states that the Tulloch is a failure as against the \$1,000 Challenge Feeder of Hendy's.

We warrant the machines to give perfect satisfaction, and to be a better and more durable Feeder than any other in the market, and will sell them as cheap as any other of its class.

For Description, Send for Circular to

J. HENDY, Sole Manufacturer,

NOS. 49 & 51 FREMONT STREET, - - - SAN FRANCISCO, CAL.

Where it Can be Seen in Operation.

HENDY'S IMPROVED AMALGAMATOR and CONCENTRATOR,
AND DEALER IN
QUARTZ MILL MACHINERY.

PICKERING ENGINE GOVERNOR.

VALLEJO FOUNDRY, October 17th, 1876.

Messrs. NEYLAN & YOUNG, San Francisco,

Agents for "PICKERING GOVERNORS."

Gents:—The 10 two-inch Improved Speed Adjusting Governors I bought of you this year for my patent Straw Burning Threshing Engines give splendid satisfaction. They far surpass for regularity of speed any Governor that I have ever seen, and I have seen all the best kinds; I have seen the main belt fly off the pulley several times this season while threshing, and the engine did not discover it, so perfectly was the speed maintained, until he was told of it; this I consider something wonderful; I consider the Governor absolutely perfect, so far as speed is concerned. I bought and put on to one of my engines a Shive Governor, to see which was the best, and after one season's trial I have no hesitation in saying they are far superior to any other Governor that I have seen or used. I wish you would send me the lowest price that you can furnish 25 Governors for next season's engines. Yours respectfully, J. L. HEALD.

The only Governor that has received awards at each of the International Exhibitions. American Institute Fair, New York, 1869, Two Medals; Mechanics' Institute Fair, Baltimore, 1865, Silver Medal; American Institute Fair, New York, 1869, Two Medals; International Exposition, Paris, 1867, One Bronze and Two Special Medals; International Exposition, Vienna, 1873, Medal of Progress and Decoration; International Exhibition, Philadelphia, 1876, Medal and Diploma.

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to

this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

H. me Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.

Superior Pianos for the People at Popular Cash Prices.

More than TEN THOUSAND prosperous families on this Coast need Ten Thousand GOLDEN PIANOS to make TEN THOUSAND HOMES MORE PLEASANT AND ATTRACTIVE.

Prices of good Pianos have long been too high. Our people could not afford to buy them. But many will

find it not only pleasant but profitable to purchase

The Brilliant and Durable

GOLDEN PIANO

Which we now offer the readers of this paper

At Greatly Reduced Popular Cash Prices.

We Guarantee them to be as represented, of superior tone, finish and durability.

Samples can be seen by calling at this office. We keep no expensive sales-rooms and attendants.

We shall sell none but superior and desirable instruments, but give our customers the benefit of prices far below any before offered on this side of the Continent.

Prices of the Golden Piano:

The Golden Piano, \$500	\$350
(UPRIGHT—C.)	
The Golden Piano, \$375	\$300
(SQUARE—No. 1.)	
The Golden Piano, \$500	\$350
(SQUARE—No. 2.)	
The Golden Piano, \$600	\$400
(SQUARE—No. 3.)	
The Golden Piano, \$800	\$450
(SQUARE—No. 4.)	

We invite our readers who wish to look at Pianos for themselves or friends, for immediate or future purchase, to call and examine our samples.

Those who cannot call will be supplied with further descriptions and recommendations by sending to this office.

To Ship and Engine Builders, Steamship Companies, Etc.

A Mechanical Engineer, having an extensive experience in Marine Engineering (especially compound) and Iron Ship Building, also in Steam Engines and Machinery in general, is open for engagement. First-class references.

Address and references can be obtained at office of Scientific Press.

Don't trifle with a poor watch when you can buy a good one of Dewey & Jordan, 433 Montgomery street, San Francisco, at prices according to the times.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO.,
Patent Solicitors.

SAN FRANCISCO, SATURDAY, MAY 19, 1877.

VOLUME XXXIV.
Number 20.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

SEWING MACHINES.—Wm. A. Dawson, S. F. This improvement relates to that particular class of sewing machines in which two or more needles, operated by the same needle arm, are used for sewing two or more parallel seams. The needles used in this class of machines have heretofore been made stationary, so that the space between the seams could not be varied, whereas it is often necessary or desirable to run the seams closer together or farther apart according to the character of the work being done. This invention provides an arrangement for adjusting these needles so that the operator can set them to suit any character or class of work. The invention can be applied to any of the double-thread sewing machines now in use. In a shuttle machine the shuttle-races can also be made adjustable, corresponding to the adjustment of the needles; but the inventor has discovered that this is not necessary, as he can obtain a sufficient width of space for ordinary work by a simple adjustment of the needles, and the employment of a looper which will insure the passage of the shuttles through the loops, even when the needles are set at a distance from them. This invention provides an important improvement in this class of sewing machines by adapting each machine to sew parallel seams at varying distances apart as desired. Double seam stitching is now being generally adopted in sewing heavy materials, and this improvement is intended to adapt the machines for this work.

WINDOW SASH.—Reed, Hoagland & Newsom, Brooklyn, Alameda county. The nature of this invention is to provide an improved screen attachment for the upper and lower sashes of windows, so that when the windows are opened the screens will automatically and simultaneously be drawn across the opening and thus prevent the entrance of insects. The improved window screens are arranged to slide like drawers into vertical boxes or recesses in the casing or wall, one of which is arranged above and one below the window opening, so that the screens can be attached to and operated by the window sashes. For upper windows this screen is provided with a suitable frame on its two ends and upper edge, while its lower edge is attached to the upper rail of the upper sash, so that when the sash is lowered the screen will be drawn out of its recess so as to cover the opening between the upper rail of the sash and the top of the window opening. The lower sash is arranged a little differently but on the same principle, except that the screen is not attached to the window permanently, so that the window can be raised if desirable without raising the screen in the upper sash. However, it is a permanent fixture, and there are no detachable fastenings to give burglars a chance to get in at night in case the window is open.

TRACE FASTENER.—Chas. S. Crittendon, S. F. This improved trace fastening is intended more particularly for coaches or hacks, although it can be used on all classes of vehicles. Around each end of the whiffletree is made a groove as wide as the trace to be fastened on it. The end of the trace is formed into a loop to fit in the groove. Upon the trace is a metal or other loop which can be slipped up against the whiffletree after the trace loop has been placed in the groove, and thus by reducing the size of the trace loop it is made to clasp the reduced portion of the whiffletree so that it cannot get out of the groove. A strap keeps the sliding loop in place and holds the sliding loop up against the whiffletree, preventing the trace loop from sliding off the groove. This trace fastener allows the pull upon the trace to come straight from the whiffletree without cramping or straining any particular part of the trace, so that it will last as long as any other part of the harness, whereas, with the ordinary fastening now in use, the trace is cramped by the fastenings so that it soon becomes broken at that point, requiring to be frequently repaired.

The Knight Water Wheel.

The engraving which we herewith present of the Knight water wheel, shows a very plain and practical piece of machinery; but, notwithstanding its simplicity, it is said to give more power for a given percentage of water than any wheel yet invented. Possessing as it does so much usefulness at a comparatively trifling cost, we have deemed it of interest to our readers to thus represent it. The buckets and the rim of the wheel are one solid piece of iron, so that that there are no parts to become at any time disarranged. The buckets receive the force of the water in the center from a slotted nozzle with three subdivisions, and the discharge is instantaneous.

This wheel was patented through the MINING AND SCIENTIFIC PRESS Patent Agency in January, 1875, and within the past year has had an unusual run, particularly in Amador county in this State, where it is best known. This is shown by the following list of mills and hoisting works

Mining Co's mill, Amador Co., Cal.; 10 stamps. J. C. Goodman, Supt.

One 8-foot wheel, hoisting from 1300-foot level, Gwin mine, Calaveras Co., Cal. Wm. Gwin, Supt.

One 6-foot wheel, running St. Patrick's mill, Newcastle, Placer Co., Cal.; 15 stamps. John Townsend, Supt.

One 8-foot wheel, hoisting and running pump, compressor and hoisting at Sheba Silver Mining Co's mine, State of Nevada.

One 8-foot wheel, running 24-stamp mill, Green Mountain Mining Co., Plumas Co. C. G. Rogers, Supt.

One 4½-foot wheel, running Luck Q. M. Co. mill; 10 stamps; Oregon.

One 8-foot wheel, running No. 3 improved Burleigh Compressor at Pittsburg and California Gold Co's mine, Smartsville, Yuba Co., Cal. Jas. Watson, Supt.

By way of further explanation it may be stated that the wheel is a hydraulic pressure one, acting by force, instead of weight of water, though of course it gets the benefit of some weight. Parties who may be interested in such machinery can gain further information, and such particulars as they may desire, by addressing Knight &

KNIGHT'S IMPROVED WATER WHEEL.

which are now using the wheel, and which we give so that those interested may communicate with any of the companies referred to as to the actual work performed, amount of water used, etc.:

One 8-foot wheel, running Oneida Co's mill, Amador Co., Cal.; 60 stamps. Rob't Robinson, Supt.

One 8-foot wheel, running Con. Amador Co's mill, Amador Co., Cal.; 40 stamps and two Hepburn pans. David Davis, Supt.

One 8-foot wheel, running Lincoln Gold Mining Co's mill, Amador Co., Cal.; 40 stamps.

One 8-foot wheel, running pump at same company's mine. S. D. R. Stewart, Supt.

One 8-foot wheel, running Keystone Con. Mining Co's mill, Amador Co., Cal.; 40 stamps.

One 4½-foot wheel, used in hoisting by reversible water power at same company's mine. O. C. Hewitt, Supt.

One 4½-foot wheel, running Original Co's mill, Amador Co., Cal.; 40 stamps, one pan, and one rock-breaker. J. R. Johns, Supt.

One 8-foot wheel, running Gover Mining Co's new mill, Amador Co., Cal.; 20 stamps.

One 8-foot wheel, running same company's old mill; 10 stamps. John Palmer, Supt.

One 6-foot wheel, running Talisman Mining Co's mill, Amador Co., Cal.; 10 stamps.

One 8-foot wheel, hoisting and driving pump at same company's mine. John Tregloan, Supt.

One 4½-foot wheel, running Bunker Hill Mining Co's mill, Amador Co., Cal.; 10 stamps. John Palmer, Supt.

One 4½-foot wheel, running Gold Mountain

Co., Sutter Creek, Amador Co., Cal.; or Almarin B. Paul, agent for the wheel, room 20, Safe Deposit building, San Francisco.

MINING SUIT.—In the Supreme Court this week the hearing on appeal was argued and submitted in the case of Silas A. Stone vs. the Geyser quicksilver mining company et al. The grounds urged for a new trial are that the evidence which went to the jury clearly showed that he had acquired a title, which had never been forfeited, to the premises in controversy; that the title neither by mining rules or regulations had been rendered void nor abandoned intentionally; that all facts showed for the defendants were, that they audaciously and illegally intruded upon plaintiff and openly endeavored to improve him out of his estate by improvements deliberately made for that purpose, after due notice of his rights. The defendant set up no pretension to title other than by locations made in the fall of 1871, and later. Therefore it was claimed that the verdict of the jury in favor of the defendant was against the law and evidence, under these points. The admission of certain testimony and the allowing of certain instructions proposed by defendants to go to the jury, are also grounds for a new trial. The respondent's counsel argued a general denial, and reviewed the testimony of the case to show that the verdict was a proper one.

The Grand Prize company, of Tuscarora district, shipped \$6,518 last Monday; the Leopard shipped \$6,130.

The Crown Point Investigation.

There was a very large meeting of the dissatisfied stockholders of the Crown Point mine, held at Mercantile Library hall, on Tuesday evening. The meeting was called to order by Dr. Cachot, who stated briefly the object of the movement. The committee appointed at a previous meeting to investigate the affairs of the company, presented an elaborate report, which was read to the stockholders. They charge the Trustees with being guilty of the grossest mismanagement and carelessness. The receipts of the company during 1875 and 1876 amounted to nearly \$5,000,000, including \$750,000 in assessments, nevertheless the mine was in debt \$135,000 on the 1st of January last, and had ceased to pay dividends. It was reported that the water had prevented the working of the lower levels; but disinterested experts had informed the committee that the trouble from this source had been greatly exaggerated, and, from this and other circumstances, the committee had concluded that interested parties were trying to freeze out the stockholders and gain control of a valuable piece of mining property. At the time when the mine ceased to pay dividends, there was sufficient low-grade ore on hand in the drifts to keep the company's mill, which is one of the best on the Pacific coast, at work for 10 years, but instead of working it at a cost of \$7 per ton in their own mill, the company had sent it all to the Nevada mills, to be reduced at an expense of from \$11 to \$13 per ton. The committee explained this state of affairs by remarking that John P. Jones is the principal owner of the Nevada mills, and John P. Jones's brother is the Superintendent of the Crown Point mine, and what is more, John P. Jackson, agent for John P. Jones, is one of the Crown Point Trustees. The committee produced a letter written by the Superintendent, S. L. Jones, to the President, John D. Fry, on the 25th of last January, in which he says that he run the low-grade ores to the Nevada mills "because the mills were under heavy expense when idle, and he thought they should be kept employed." The committee were of the opinion that the mine had been worked in the interest of the Nevada mill owners instead of the Crown Point stockholders.

The committee are of the opinion that it was time a change was made and the mine run on a better basis, which is probably the opinion of almost any body who is in favor of economical mine management. As the books of the company close on the 25th instant, the committee request all stockholders to transfer their stock before that time, so that it can be used to turn out the present managers at the annual election. The committee stated that after the present assessment has been applied to the debts of the company there will still remain a debt of \$65,000, which will necessitate another assessment of \$1 per share, if a change is not effected.

The Crown Point mine made for itself in times past an enviable record as a bullion producer and dividend payer, and it is greatly to be regretted that it should have fallen into the list of assessment levying mines. Still, if the statements of the committee are to be credited, it is small wonder that the mine was unprofitable. It is the old cause of complaint over again, that the managers were looking out more for the interests of mills which they owned, than for the interests of the stockholders whom they represented. This sort of thing will continue of course, until the persons doing it are brought up with a round turn and properly punished. People will not stand any such nonsense much longer, and this special abuse, one of the greatest connected with mining matters on the Comstock, must be put a stop to summarily. Just at this moment when mining stocks are at a low ebb and the confidence of the people shaken in mining matters, it is a good time to bring the matter forward so that the practice may be abolished forever and a reform made in this as well as other things.

The Ophir mine report for April shows 642 tons of ore shipped to the mill; 410 tons worked, yielding \$11,731, or \$28.75 per ton, and 232 tons carried over into May account. Only one mill was employed last month on selected ore at a special rate of \$7 per ton.

CORRESPONDENCE.

Mining Items from Siskiyou County.

EDITORS PRESS.—We had a frost last night and ice this morning, a slight shower yesterday, cloudy to-day. Last Tuesday, the 1st, I paid a flying visit to Oro Fino, a little burg about 16 miles distant. Oro Fino, in 1862, was a flourishing mining town. There were five saloons in full blast, four stores, etc. The mines were then placer for gold, now quartz is all the go. There are several claims near the town that prospect well. Madam rumor has it that five or six mills will be erected there this summer. I found one store just opening; first they have had for four or five years, I am told. I expect to pay Oro Fino another visit soon, and, if I can find the time, will visit Quartz valley and the numerous mines in the vicinity, and may be, pick up an item of interest.

Last week, I had the pleasure of visiting South Fork. This is another old mining town, and is to-day one of the best mining camps in this vicinity. Some of the best claims are owned and run by Chinamen. I learn that all the claims are paying. My friend Cogings owns one of the best claims on the creek. The people here are as sociable and well informed as any I ever met, believing in living while they do live, and they surely enjoy life as they go along. I expect to visit South Fork in a week again, and will have more to say about it, the mines and people, etc.

Cory & Kingry passed, this afternoon, with two loads of quartz, bound for Johnston's mill, Oro Fino, to be crushed. They promised to let me know how it "panned out" as soon as the results are known. I picked up a piece of rock at random, and saw several colors in it.

R. D. NUNNALLY.

French Creek, May 7th, 1877.

Prospects of Eureka District.

In an interview with a gentleman prominently identified with mining affairs in this section, who has just returned from a business trip to San Francisco, we were informed that Eureka district is taking a rank in mining circles commensurate with the importance of developments made all along the line. He informs us that he was overwhelmed with inquiries in regard to the nature of the deposits, their extent and formation, and he has no doubt that a large flow of capital will be turned this way as soon as the market experiences a reaction. At present there is no money obtainable for the purpose of developing or working any mine, no matter how safe or profitable an investment it may be. People have become so frightened at the outlook that nothing will persuade them to let go of their purse strings. In this connection it is pleasant to note that Eureka stocks have not participated in the distrust, but instead have bravely held their own during the depreciation in values. Coming nearer home and feeling the public pulse on the situation, we are impressed with the general hopefulness expressed on every side. All concede the present stagnation, and admit the dull times, but while taking in sail to baffle the untoward winds, agree that it can be but temporary. Wait until the settlement of the suits, and you will see things booming, is the usual commentary, and that event is looked forward to as the end of all troubles, and the dawn of a better day. We are inclined to accept this view, and we think that no one can survey the district, and take into account the prospects and developments, without conceding the fact of its ultimate importance in the mining world.

The Ore Channel.

Commencing at the Hamburg on the south extremity of the vein as far as explored, we find a mine that in itself would, if situated in any other district, give it fame and prominence at once. We gave a mere sketch of a portion of the mine in our columns a short time ago, and our statements were not exaggerated in the least. The section of the mine that we visited was one mass of high grade ore from the grass roots to the lowest depths explored, and there is enough ore in sight, provided that no further developments were made, to keep four furnaces steadily employed in reducing it for the next 12 months to come. There are 2,000 tons on the dump, and teams are employed in transporting it from the mine to the furnace. On the completion of the hoisting works, stoping and extracting will commence, and the Hamburg will employ 200 men about the mine and works.

Along the Vein.

And a short distance to the north, lies the Connolly. The litigation that has retarded the development of this mine has been settled, and we believe that active operations will soon be commenced. It is a notorious fact that there is a large ore body uncovered, and the Connolly will soon become a bulwark producer of some magnitude. From the Connolly to the Dunderberg and Atlas is but a stone's throw. Here is another rich property that is involved in litigation. The mine is known to contain permanent and high grade bodies of ore, and the settlement of the question of title will set loose a stream of wealth from its shaft and levels. The Jackson is the next developed mine, and its lowest levels are teeming with ore awaiting the starting

up of the Eureka furnaces to add its quota to the bulwark product. The K K steadily turns out 60 tons of ore per day from the mine, and the smoke from its furnaces never ceases only when it is necessary to repair them. The Eureka Consolidated is too well known for us to comment on, or boast of. There is no doubt that there is more ore in sight and awaiting the labors of the pick and drill than has ever been found in its hidden depths at any previous time since its discovery. The settlement of the mining suit between it and its neighbor on the south will unlock treasures that will make the "Bonanzas" look to their laurels. The Richmond comes to the front with new discoveries in the western part of its mine, a section removed from all ground in dispute. No matter which way the suit will be decided, it will remain one of the chief mines of the district. Crossing over to Adams Hill, we find that mine steadily producing ore. Even the very low grade vein matter in this mine is valuable, from the fact that it is a splendid flux for the more refractory ores of other mines, and for that reason is sought for and purchased at the various furnaces at rates far above the usual prices allowed for ores from outside mines.

Prospect Mountain.

Thus in a general way we have alluded to some of the more prominent mines on the great vein that can be traced for a distance of five miles. Every one of them have the brightest prospects before them and will be adding their accumulated wealth to the coffers of the world in the near future. We have not taken into account the great ore deposit existing on Prospect mountain. That portion of the district is still in embryo, and although it has produced thousands of tons of high grade ore, yet it is a fact that the deepest shaft on the mountain has only gone down 280 feet. Such a vast network of veins and ore deposits is not to be found in any other section of the State, and of itself is sufficient to establish the fame of Eureka. It is not strange, that with all this wealth laying at our doors, that the abiding faith of the business men of Eureka in the permanence and future prosperity of the country should be firm and hopeful, nor that our district should meet with the recognition abroad that its splendid showing merits? Forty million dollars added to the grand aggregate of bullion produced by the State of Nevada is not a bad showing for seven years' work, and there is no reason why treble that amount should not be sent forth from the mines of Eureka in the next seven years. We predicate our statements and prophecies on what is actually in sight, and any one acquainted with the status of the mines will indorse us. A great vein, vast ore deposits, permanence assured by deep working, continued developments and the endorsement of those best qualified to judge, enables us all to tide over the temporary dullness caused by litigation, and not from any giving out of the vast wealth that nature has so lavishly bestowed on this portion of the base range.—*Eureka Sentinel.*

Milling Improvements.

The Virginia Enterprise says: The new tailings mill, known as the Omega, situated at the junction of Six and Seven-mile canyons, has been completed and will start up to-morrow. For the purposes for which it was designed, it is one of the completest and most convenient mills on the Comstock. It was built in accordance with plans and specifications furnished by Mr. Patten, architect, and, as will be remembered, is on the site of the old Gould & Curry mill, the engine itself resting on the old engine-bed. The mill is provided with 20 large-size pans and 10 settlers, and has a working capacity of about 200 tons per day. It will furnish employment for 100 men in all. The machinery is driven by a

Corliss Engine

Of 400-horse power. The engine, which is one of the finest on the coast, was purchased a short time ago from the Savage mining company. It cost originally \$60,000. The machinery of the mill is entirely new, and combines all the modern improvements tending to economy and convenience. The mill is supplied with tailings from the Consolidated Virginia and California mines, and has a set of sluices 1,200 feet long and 24 feet wide. It is also provided with three of Towle's concentrating tables. The owners of the mill chose for

Superintendent,

James Woodbury, who for several years past has acted Superintendent of the Mariposa mill, to the successful management of which Mr. Woodbury owes his appointment to the new position. The working of slimes and tailings involves a heavy expense in the line of chemicals, and a large amount of experience, skill and prudence on the part of the management to make the business at all profitable. The heaviest item of expense is for sulphate of copper, the consumption of which at the Omega for a month of 31 days, at 10 cents a pound, amounts to over \$27,500. There are required in addition from 15 to 18 car-loads of salt per month, with a daily consumption of quicksilver, amounting to 225 pounds, at 40 cents per pound.

Unhealthy Work.

The men employed about the mills, who receive the highest wages, are the amalgamators, owing to the unhealthy character of their work. Men are seldom found who are able to follow the business for a period of over two or three years, their systems becoming so thoroughly charged with mercury and other chemicals that

they become subject to the "shakes." After working in the open air for a time the poison is eliminated from the system. The high wages paid to amalgamators is the only temptation for a man to engage in the business. Among the amalgamators we noticed a son of Dr. Berthier, lately of this city. The

Pay-Roll

Of the Omega, for construction purposes for the past month, amounted to \$12,000; Mariposa mill, for labor, \$3,000. The chief engineer at the Omega is Joseph McNab, a young man well fitted for the position. The general manager of the new mill, as well as all the other mills running on Consolidated Virginia or California ore, is Mr. D. B. Lyman.

Other Mills.

All the mills in Six and Seven-mile canyons, with the exception of perhaps the Lady Bryan, are running—the Mariposa on tailings. The Land mill crushes 45 tons per day of Chollar rock; the Winfield 45 tons of Ophir. Parke's Railroad and Express mills are running on tailings; the Empire State mill on Chollar ore; the Nevada mill on tailings. The Sacramento mill, on the Geiger grade, is being thoroughly overhauled and will start up in a week, under the superintendency of W. J. Westerfield. The large mill known as the Eureka, is running on Justice ore; a majority of the smaller mills at Silver City being hung up for the present.

Wet Treatment of Silicate Ores.

The invention of Mr. Mieczyslas Kaminski, of Paris, relates to improvements in the wet treatment of silicate ores of copper, nickel, and cobalt, to obtain the metals or metallic salts. The natural silicates of the form $\text{Cu O Si O}_3 \text{ H}$ are treated with strong acid, which displaces the silica, and produces a soluble salt of the metal. The hydrate of silica, which results from the reaction, is also soluble. This silica is separated by dehydrating it at a dull-red heat. The heat ought to be such that the metallic salt will not be decomposed whilst the silica is dehydrated. The dehydrated silica, now being insoluble, is precipitated when water is added, and it is now only necessary to decant or filter and wash the precipitate of silica, and the whole of the metallic salt is thus separated; such is the system of treatment. Suppose that silicate of copper ($\text{Cu O Si O}_3 \text{ H O}$) is to be treated, the mineral is ground, and a quantity of sulphuric acid proportional to the amount of copper in the ore is mixed with it; it is then exposed to the air for the time necessary for it to form into a pasty and gelatinous mass. The magma is then placed in an iron pan, and submitted to a dull-red heat in any convenient furnace. The completion of the reaction is shown by the cessation of all volatilization vaporization of water or acid in excess in the magma. The resulting cake is treated with water; it disintegrates, the sulphate of copper dissolves, the temperature augments, the silica, which has been dehydrated by the heat, and has become insoluble, remains in the form of an excessively fine white powder. All that now need be done is to filter with bags, and a limpid liquor is obtained, which contains all the copper in the form of sulphate. The precipitate of silicate is easily washed without the necessity of agitation, so as to remove the last traces of sulphate of copper. The bags, if they are sufficiently large, can, before the final washing of the precipitate, receive successively large quantities of the silica. Sulphuric acid, nitric, hydrochloric, acetic, etc., may be used indifferently, but will produce the corresponding metallic salts.

If it be required to treat silicate of nickel, such as is found in the minerals of New Caledonia, having the composition of a double salt, silicate of nickel with the silicate of magnesia mixed with the oxide or the silicate of iron, the mineral in question is dissolved in muriatic acid of commerce, diluted with double its weight of water. For this operation the mineral should be finely powdered, and passed through a sieve. The quantity of acid should represent the equivalent corresponding to the nickel, the magnesia, and the iron contained in the mineral. The solution is made in stoneware vessels heated by an oil bath. The operation is complete when the residue, carefully washed, has lost its green color. The solution is allowed to settle and is drawn off; it contains chlorides of nickel, of magnesia, and of iron. After it has been allowed to stand for some hours the iron is peroxidized by adding an aqueous solution of chlorine, in such quantity that there may be chlorine equivalent to the iron requiring to be peroxidized. This quantity of chlorine will be quite small, for it has only to peroxidize the iron found in a state of protoxide. The rest of the iron exists as peroxides in the mineral. The iron thus oxidized is precipitated from the solution by carbonate of magnesia, the magnesia combines with the chlorine of the chloride, and disengages the peroxide. The quantity of carbonate of magnesia required is an equivalent of magnesia for each equivalent of iron to be precipitated. This carbonate of magnesia is obtained in a pure state from the mineral under treatment in the manner hereinafter described. Air is employed to agitate the liquid, and to remove excess of chlorine to prevent peroxidation of the chloride of nickel.

After that the liquid has been freed from carbonic acid by the action of the air or by agitation, the oxide of iron is found to be completely precipitated. After it has been left for about 12 hours the liquid is passed through a filter; it then only contains chloride of nickel and chloride of magnesia, and it is quite neutral. It

is placed in copper bowls, and carbonate of soda is added in quantity almost equivalent to the nickel contained, and it is heated. The carbonate of soda precipitates both the nickel and the magnesia in the form of carbonates, but the carbonate of magnesia becomes decomposed by heat in the presence of the chloride of nickel contained in the liquid, and returns as chloride into the solution, depositing the nickel in the form of carbonate. It should be observed that to avoid having carbonate of magnesia in the deposit it is necessary to have a little less soda than there is nickel in the solution. The remaining nickel will be recovered, as hereinafter described.

The liquid with the deposit is passed a second time through the filter press; the deposit, which is carbonate of nickel, is carefully washed with water free from earthy salts; then pressed, dried, and set aside for reduction with wood charcoal in a close crucible at a white-red heat continued for two hours or more. The carbonic acid of the carbonate of nickel, as well as its oxide, at this heat is reduced by the carbon forming oxide of carbon, which burns, leaving in the crucible pure metallic nickel mixed mechanically only with carbon, which separates from it when it is thrown into water. The nickel thus obtained in a spongy state is quite pure, and may be melted with other metals to form well-known alloys, or it may be employed in the metallic state. The liquid obtained from the second filtration containing traces of nickel besides chlorides of magnesia and of sodium is again treated by carbonate of soda for the precipitation of the rest of the nickel and of a part of the magnesia; it yields carbonate of magnesia and of nickel, which serves in the next operation for the precipitation of the iron, as has been already described. The remaining liquid, when submitted to evaporation, yields common salt, which represents all the soda employed as carbonate, the mother liquor (which is but chloride of magnesium) further evaporated and heated in stoneware vessels to a temperature of about 150°. Where a jet of steam is passed through the mass yields hydrochloric acid. The magnesia thus obtained is also a useful product.—*London Mining Journal.*

Uniting Iron and Steel.

It is well known that in employing either iron or steel for various purposes of manufacture, the result desired is frequently only partially attained; as, for instance, tools and other articles made entirely of steel, though possessing great hardness, do not combine therewith the requisite degree of tenacity, while articles made entirely of iron, though possessing great tenacity, are completely wanting in the necessary hardness and elasticity. These inconveniences can only be removed when both steel and iron are so intimately combined as to form a perfect union, whereby the deficiencies existing in either metal are atoned for by the qualities of the other. For this purpose Messrs. Asbeck, Osthann, Eicken, of Hagen, Westphalia, manufacture a mass consisting partly of steel and partly of iron, and which they call steel-iron. The novelty, if any, consists in introducing a thin plate of iron at the junction. A chill of cast-iron is divided into two compartments, either by a transverse plate or by standing a tube within it, and the metals to be united are poured into the separate compartments. Previous to fusion, both metals are refined and purified from all substances pernicious to their welding, after which the steel in fusion, as also the soft iron in fusion, are at the same time and in similar proportions cast into the divided chill, the dividing plate of sheet-iron in which welds both the steel and iron so intimately together that they form a perfect union, the sheet-iron serving at the same time not only as a preservative against the compounding of the two metals, but also as a means of their welding. The success of the proceeding depends greatly upon the careful and peculiar preparation of the materials and upon their quality and fitness for welding, as also upon the thickness of the sheet-iron plate, which must be sufficiently thick to resist the burning influences of the metals in fusion, and yet not too thick, otherwise the materials in fusion during their rising in the chill, will not bring the plate to welding. The requisite thickness of the sheet-iron is determined by experience, and the dimensions differ naturally in proportion to the transverse cut of the different blocks to be made. The steel and iron are placed on one or other of the dividing sheets or tubes, according to the purposes for which the mass is required. The combination is said to be applicable to various purposes. It is explained, for instance, that it will be advantageous to employ steel-iron for rails, anvils and armor-plates, as the hard steel will diminish the wearing; and armor-plates for safes, to render them burglar-proof, when made of this improved material, will, owing to the steel therein, resist the hardest drill, while at the same time the iron preserves such plates from all danger of fracture from blows. All such parts of machinery or tools as have either to resist or produce a strong pressure or strong concussion, such as rollers or axles, are greatly superior when made of this improved material, which combine great internal tenacity with external hardness. The wear of the external material is reduced to a minimum, whilst its internal softness gives it considerable tenacity, and prevents breaking.—*London Mining Journal.*

MECHANICAL PROGRESS.

Science and Practice in Building.

From an article on "Theory and Practice in Architecture," by James C. Bayles, in the current number of the *International Review*, we take the following, showing the need of progressive ideas in this department of industry: "Of the evils incident to cheap and temporary construction, the most serious are our heavy annual losses from fire. The valuation of the property annually destroyed by fire in the United States may be roughly averaged at \$100,000,000. In addition to this enormous destruction of values, we must bear the cost of fire protection systems and of insurance. As regards fire-proof construction, there exists no very close relation between the knowledge we have gained from experience and the methods and materials we commonly employ in house building. That so many buildings popularly considered fire-proof were destroyed in Chicago and Boston, and that in the furnace breath of those great conflagrations even the most incombustible materials fell in crumbling ruin, cannot be accepted as proof that it is useless to seek security from fire.

"It is too much to expect that there will ever be, in our average architectural practice, a close approximation to the measure of our scientific knowledge. If it follows, even a long way behind the footprints of invention and discovery, it will be as rapidly progressive as we can hope to see it. Generally speaking, we gain knowledge a good deal faster than we can apply it practically, and our progress toward higher standards in architecture will, and should be, characterized by a judicious conservatism. The material interests involved are large, and should be carefully guarded by the conscientious architect. We cannot, therefore, expect that he will make haste to utilize every new fact which may be added to the sum of the world's knowledge; but we have a right to insist that he shall not carry his conservatism too far, and cling to systems and methods entailing evils from which we naturally and properly look to him for protection. In these matters there should be a much closer relation than now exists between theory and practice in house building, and if the conscientious architect will first educate himself in those branches of his art in which the disparity is greatest, he will find it an easy task to bring about the desired reforms. In thus educating the public, by placing before them the results of his education, he will open for himself a broader and nobler field of usefulness, with fewer restrictions and limitations than now hamper him."

IMPROVED MANUFACTURE OF SAWS.—Circular saws of all sizes are now produced without hammering, and this, too, of a quality alleged to be superior to anything heretofore produced. By the ordinary method, the saw after being hardened and tempered, has been through the hands of smiths, hammerers and blockers, as they are termed, for the purpose of removing the irregularities, as far as possible, by hammering them with heavy hammers on anvils, leaving the saw, when complete, irregular in its tension—a source of continual expense and annoyance to the user, involving serious interruptions to business. In avoiding the system of hammering, and by means of improved processes and appliances, an article is now produced which possesses the great advantage of being entirely free from uneven strain or buckle—a result never before attained. The hammering process required the use of a very mild quality of steel, or the percentage of loss by breakage would be ruinous. By means of the improved process, a very high quality of steel is available, the result being that saws are produced which, by actual tests, hold an edge twice as long. The success of the process requiring a perfectly uniform heat, insures an absolutely uniform temper, and the same file and set in a more satisfactory manner. Being also free from uneven strain or buckle, they stand up to their work better than a hammered saw, and, as they are reduced in size, they retain their original shape or position. *Cincinnati Trade List.*

WIRE WORKING.—Iron says that a machine for corrugating or indenting iron wire for trellis work has been patented by Mr. P. Joannes. By means of this machine crude iron wire, in other words, not annealed, can be prepared for putting together in diamond-shaped or square lattice work, without riveting or twisting, as is the custom at present. Wire of unusual thickness can be used, up to, say, half an inch in diameter, and when prepared by the machine the lattice can be manufactured with great rapidity. No lattice work heretofore made can compare with the product of this machine in point of solidity, strength and durability.

INDUSTRY IN SOUTH AUSTRALIA.—Manufactures are extending rapidly in this colony. There are engineering plants, besides those of the government, of no mean order, boiler-makers, with steam-riveting machines and other machinery of the first order. There are no fewer than 86 agricultural-implement works, where large numbers of "strippers" are turned out annually. To these machines, South Australia owes very much, as without them wheat growing would not be of much profit; they save labor immensely.

Brains in American Machines.

A public dinner was recently given in Cincinnati to the Hon. A. T. Goshorn, Director-General of our late Centennial exhibition. In response to the toast, "American Industry," Mr. Goshorn made an interesting speech, from which we extract as follows: "The London *Times* is the expression of the highest public opinion, and therefore the best authority, in England. The leading article of the *Times* of March 1st is a discussion of the importance of the representation of England at the Paris exposition. It speaks of the superiority of the trained intelligence of the workmen of Germany and America—and so 'the competition at Philadelphia was not altogether satisfactory to us.' The fineness of the mechanical work shown at Philadelphia 'could not have been exceeded if every man who had any share in its production had originally conceived it and had been solely interested in its success.'

"The Thunder of London is right. There are brains in American industry. Why, the great Corliss engine at the Centennial exhibition had brains, for I saw it pick up its own valves and drop them when there was just steam enough on, and very few men can be trusted to do that. It had so much sense it would not waste one pound of steam, for it knew that steam cost money. American brains shine in the finish and fitness of the work that is commanding even the markets of Asia. It is the busy brain behind the cunning hand that guides the great artisan to perfect his workmanship, just as the colors of the artist must be mixed with brains if they are to be radiant forever.

IRON AND STEEL FROM THE ORE.—A European journal reports that at the recent meeting of the Technical Society for Metallurgists in Dusseldorf, engineer Blair made some remarks on this interesting topic, mentioning, among other facts, that this recently devised process had found greater application than that of Chenot, Gault or Siemens. After explaining the principles upon which the reduction of the ore was based, he remarked that the sponge obtained was melted in a cupola furnace and then mixed with molten cast-iron in a Martin's furnace. Unfortunately the sponge, as it floats on the surface of the cast-iron, is greatly subjected to the oxidizing influence of the air. The cost of production is about \$35 per ton, exclusive of the cost of the ore, and requires about a ton of combustibles per ton of iron. The product is said to be of the finest quality. Owing to the fact that the temperature in this process does not rise as high as in that of Chenot, Siemens and others, the phosphorus, sulphur, and other impurities are not extracted from their combinations in the ore, and consequently do not contaminate the iron. This utilization of poor ores makes the Blair process preferable to the others—although even in the Blair the quality of the product depends much on that of the ore, the best ores yield the best iron.

STEAM POWER.—Dr. Engel, the eminent and well-known head of the Statistical Bureau at Berlin, in a recent work estimates the labor saving effects of the steam motive power at present in use as follows: "The aggregate steam power in use in the world is at present three and one-half millions horse-power employed in stationary engines, and ten millions horse-power in locomotive engines. This force is maintained without the consumption of animal food, except by the miners who dig the coals, and the force maintained in their muscles is to the force generated by the product of their labor about 1 to 1,000. This steam power is equal to the working force of 25 millions of horses, and one horse consumes three times as much food as one man. The steam power, therefore, is equivalent to the saving of food for 75 millions of human beings. Further, three power-looms, attended by one man, produce 78 pieces of cotton fabric, against four pieces produced by one hand-loom, worked by one man in the year 1800. A carpenter's planing machine does the work of twenty men."

PROGRESS OF AMERICAN MANUFACTURES.—American manufacturers are penetrating Europe to such an extent as to cause a panic in a direction heretofore unheard from. They are sending soaps abroad in large quantities, which are selling there in preference to all others. American toilet soaps are replacing the French toilet soaps in their own markets. Partly on this account, as well as from other causes, there is a "soap panic" reported from Marseilles. There were 35,000 people employed there in that industry, and some of them are thrown out of work by the enforced idleness of the factories. American-made boots are making inroads upon Europe, and the clamor at the invasion is heard from the shoemakers of Switzerland and other continental countries. The Berlin *Shoemakers' Gazette* says that American boots are sold in Switzerland at \$2.90 per pair, and this has suddenly put a stop to the exportation of boots and shoes to America, by opening competition on their own ground.

LIFE OF CORNISH MACHINERY.—An interesting fact connected with the life of Cornish machinery was mentioned by Mr. West, at the recent meeting of East Caradon and Marke Valley mines. He said he had erected, about 40 years since, the first steam-engine on the mines, and it was now looking almost as good as new. The machinery generally was in very good condition, and would be of little expense for some time to come.

SCIENTIFIC PROGRESS.

The Physical Condition of Jupiter and Saturn.

Prof. R. A. Proctor comes to the defense of his views that Jupiter and Saturn are hot planets, and the *Polytechnic* has a summary of his claims. His view has been attacked by Prof. Vogel in an essay describing researches with the spectroscope as to the light of those planets—researches which have won for Prof. Vogel a prize from the Copenhagen Academy. The attack was based on the evidence that the spectra of bands and lines in those planets were similar to those of our own atmosphere, occasioned by the presence of aqueous vapor. Prof. Proctor argues with force against the conclusion that aqueous vapors constitute the chief envelope of the larger planets. According to the accepted theory of their formation, those planets are much older than the earth, but Professor Proctor shows, by estimate, have not yet had time to cool, owing to their enormous bulk. Their lack of density can be best explained by supposing that their condensation is still prevented by internal heat. Such atmospheres as they evidently have would be, unless continually expanded by heat, compressed and solidified by the gravity of such great masses. The cloud-belts present aspects and changes which can be explained best if we believe that they exhibit the surface of up-rusting heated vapors, with cloud-like summits. These clouds and belts bear no relation to the diurnal or annual exposure of the surface to the sun's rays, and hence their changes must be referred to local causes. The outlines of these planets have frequently been noticed as varying from a circular form, and a satellite occulted by the edge of the planet has reappeared briefly, just after concealment; such facts may be readily explained if the surrounding atmosphere is more than 2,000 miles deep and is subject to great mutations. Finally, the light of the planets is two and one-half times greater than that which pure sandstone would reflect; hence it seems probable that they produce light. Prof. Proctor thinks that those planets will not be in condition to support life for many millions of years.

DETERMINATION OF IODINE BY THE BLOWPIPE.—At a late meeting of the New York Academy of Sciences, a paper was read on this subject by Mr. Walter B. Devereux. The determination of iodine in the presence of the other halogens, chlorine and bromine, has hitherto been a difficult and uncertain operation in blowpipe analysis. Mr. Devereux takes advantage of the well-known property which sulphate of copper possesses, of decomposing metallic iodides and liberating the iodine. The substance to be tested is mixed with one-third its weight of pulverized sulphate of copper, and the mixture is introduced into a glass tube closed at one end and heated. The iodine is easily recognized by the violet color of its vapor, or by holding a piece of moistened starch paper at the open end of the tube, taking care that the paper does not become heated, which would destroy the blue color of the iodide of starch. This precaution is more especially necessary in the case of iodide of silver, which requires a high heat for its decomposition. At the close of Mr. Devereux's remarks, Professor Eggleston spoke of the great value of this test, and expressed the hope that equally simple tests might be found for chlorine and bromine when mixed together.

ELECTRICAL EXPERIMENT.—We find the following in the *English Mechanic*: If an ebonite electrophorus be whipped with a fox-tail, it is negatively excited, and the condenser gives positive sparks. If, again, the electrophorus be rubbed with leather on which is some mosaic gold, the ebonite disc is positively excited, and the condenser gives negative sparks. It is stated by M. Schlosser, however (*Pogg. Ann.*), that if the same ebonite disc be excited on one side with the fox-tail, on the other with mosaic gold on leather, one may at any moment obtain from the same disc positive or negative electricity, according as the one or the other surface of the electrophorus is used as the source. The most important point in this double excitation is the very much greater length of spark, as is readily observed by the eye. On the other hand, considerably shorter sparks are obtained from the same electrophorus when both sides are similarly excited; for example, whipped with the fox-tail.

THE DOG STAR.—From an examination of the observations of the minute star, around which Sirius is revolving, Mr. Wilson, of Rugby, concludes that its period of revolution is 200 years, in an orbit 50 times that of the earth. He also shows that while the sum of the masses of Sirius and its companion is about three times that of the sun, its light, according to the old method of calculation, is more than 200 times that of the sun.

COAL IN ALABAMA.—Dr. Eugene A. Smith, State Geologist of Alabama, in his report of progress for 1876, presents a new map of the Coosa coal field, from which it appears that at least 300 square miles of territory should be added to the previously-known limits of the coal measures. This is equal to five-eighths of the total anthracite areas of Pennsylvania.

The Gastric Fluid.

Dr. Charles Richet read a paper before the French Academy of Sciences recently, in which he treated of the acidity of the gastric juice in man. For some time Prof. Verneuil had a young patient under his care, who labored under the strange affection of having his oesophagus, or upper extremity of the alimentary canal so contracted as to render the passage not only of food or drink, but even of an instrument, quite impossible. The Professor had recourse to gastrotomy, an operation until then considered mortal, but which, in this case, succeeded perfectly. An incision made in the stomach, and kept open artificially, has been transformed into a regular fistula, through which food and drink are administered; and in this state the young man not only lives, but is a useful servant of the hospital. Dr. Richet, having devoted particular attention to this subject, and examined the working of the stomach day by day, through the fistula in question, last week communicated the results obtained to the Academy.

They are as follows: (1) The average acidity of gastric juice, whether pure or mixed with food, is equal to 1.7 grammes of hydrochloric acid per 1,000 of liquid. It has never been observed to be lower than 0.5 or higher than 3.2. (2) The quantity of liquid contained in the stomach exercises no influence on its acidity, which remains nearly invariable, whether the stomach be empty or filled with aliment. (3) Wine and alcohol increase the acidity of the stomach; cane-sugar diminishes it. (4) If acid or alkaline liquids be injected, the gastric ones tend rapidly to resume their normal acidity, so that, about an hour after the injection, the stomach has regained its average acidity. (5) The gastric juice is more acid during digestion than before or after. (6) There is a slight increase of acidity toward the end of digestion. (7) The sensations of hunger and thirst do not depend either on the state of acidity or on that of vacuity of the stomach. Such are the results as to acidity, but there are a few others of some interest. Thus fecula, fat and meat may stay in the stomach for three or four hours, milk is digested in the course of an hour and a half; water and alcohol are absorbed much faster, in the course of from 35 to 45 minutes. Food is not transmitted to the pylorus successively, but all in a block.

THE POWER IN NATURE.—The power actually at work at present in producing rain, and so, indirectly, in leveling the earth's surface, is enormous. The amount of heat required to evaporate a quantity of water which would cover an area of 100 square miles to the depth of one inch, would be equal to the heat which would be produced by the combustion of half a million tons of coal, and that the amount of force of which this consumption of heat would be the equivalent, corresponds to that which would be required to raise a weight of upward of 1,000,000,000 of tons to a height of a mile. When we remember that the land surface of our earth amounts to about 50,000,000 of square miles, we perceive how enormous must be the force-equivalent of the annual rainfall of our earth. We are apt to overlook, when contemplating the silent and seemingly quiet process of nature, such as the formation of the rain-cloud, or the precipitation of rain, the tremendous energy of the forces really causing these processes. "I have seen," says Professor Tyndall, "the wild stone-avalanches of the Alps, which smoke and thunder down the declivities with a vehemence almost sufficient to stun the observer. I have also seen snow-flakes descending so softly as not to hurt the fragile spangles of which they were composed; yet to produce from aqueous vapor a quantity which a child could carry of that tender material, demands an exertion of energy competent to gather up the shattered blocks of the largest stone-avalanche I have ever seen and pitch them to twice the height from which they fell."

SUGAR MAKING.—On the subject of sugar making, the Ipswich *Observer* writes: "Mr. Eastes, of Beenhedge, has made a most astounding discovery in sugar making. He claimed to be able to crystallize the whole of the juice and leave no molasses. He tested his discovery at Dart's mill, near Brisbane and the result was astonishing. He experimented on Chigacca ratoon juice marking 10° Beaume, and from 1,900 gallons was produced 2,400 pounds of beautiful white sugar, equal to the refined of Yengarie, and not a pint of molasses! It was finished in vacuum pans, and came out with only a little moisture, which the centrifugal soon removed. This is assuredly the precursor of a revolution in sugar making, and the magnitude of its importance is tremendous."

PRIZE FOR A METHOD OF DETECTING ADULTERATIONS OF BUTTER.—*Dingler's Journal* announces that the bureau of the Leipzig Pharmaceutical Union, offers a prize of 300 marks for discovery of a sure and practical method for the detection of adulteration of butter by other fatty substances. Professors Dr. Heintz, in Halle, and Dr. Knop, in Leipzig, have consented to act with Herr Kohlmann as judges in awarding the prize. Each competing essay is to be provided with a motto and accompanied by a sealed note, containing the motto on the outside and the author's name on the inside, and both are to be forwarded to Herr Kohlmann, apothecary, in Leipzig-Reudnitz, before September 30th, 1877.

New Safety Appliance for Mine Cages.

At the Brussels exhibition were exhibited several safety appliances for mine cages, which the *Colliery Guardian* describes:

The system of parachute, or safety appliance, designed by M. Charles Cousin, of Conde, permits of bodies launched into mid air, being stopped progressively without shock or damage, by means of a graduated series of weights which come into action successively, until a complete stoppage is secured.

This safety cage was entered in Class VI. (France), and received honorable mention from the judges; its principle was demonstrated to those interested in the matter, in the following simple manner: A cotton thread, passed over a pulley at a considerable height from the floor, carried at one end, and distant 80 centimeters (31 inches) from the floor, a weight of 100 grammes (3½ oz.), represented by a small glass quite full of water. The other end was provided with a graduated series of weights resting on the floor, but not fastened to it in any way. By pulling this end of the thread, the glass of water was raised to about 30 meters (98½ feet), and then left to itself. The glass fell, of course, like a bullet, with the normal velocity due to gravity, until within 80 centimeters of the floor, when it began to raise the weights at the other end of the thread, each one of them in succession being heavier than the last; so that the weight of the glass added to the velocity due to the height of fall, was gradually counterbalanced. As the thread could only sustain 100 grammes at each end, and the addition of the weight of a gramme on one side or the other, would cause it to break, it is evident that it did not experience a shake equivalent to one gramme, nor the least shock, since it did not allow a single drop of water to be spilled, and also resisted.

The application of this system to a mine cage is made as follows: Independently of the winding rope, a rope called by its inventor "the safety rope," passes over two pulleys above the pit mouth. Both ends reach down to the bottom of the shaft, and both are provided with a graduated series of weights, calculated so as to counterbalance the weight of the cage and tubs added to the impetus of the accelerated motion due to gravity. It is, therefore, evident that this series of weights would be a match for any fall that could occur. The safety rope is maintained at a certain tension by a supplementary weight placed over each series. The cages are provided with a simple wedge arrangement, which ensures the gripping of the safety rope, if the winding rope should break. It consists of a transverse lever, carrying the wedge at its end, and on the other side a spring which brings back this lever to a horizontal position when the tension of the winding rope is removed owing to its breaking. A kind of rectangular box is arranged over the wedge, and serves as a guide sliding over the safety rope in the normal state of working. In the event of the winding rope breaking, the wedge tightens itself in the box, it there closes more and more tightly on the safety rope on which it pulls with all the weight of the cages; but, as this rope, instead of being fixed, carries at its other end a graduated series of weights, it raises the latter in succession until it comes insensibly to rest. It is asserted that never, at any speed, has a small glass full of water, placed on the tubs, lost a drop of its contents.

To this safety cage is added a spring in the form of a horse-shoe, called by the inventor "a regulator of the winding rope." The object of this spring is to keep the winding rope constantly taut, when, on account of the settling of the measures, or any other cause, the cages are arrested in their ascent by too great friction against the guides. In such a case the spring opens and keeps the rope restricted, so as to prevent the spring of the safety cage from coming into action unnecessarily.

Lastly, a disengaging hook is added, which consists of an arrangement of five vertical wrought-iron rods, the middle one being connected to the winding rope so as to be released at the critical moment, but then only. The two outside rods represent a lever of the first kind, which carries a bolt, jointed at each end, and passing through the three middle olive rods; at the other end, which is curved in the shape of an olive, this lever is provided with a spring which keeps the bolt in its place. One of the bolts is placed higher and the other lower, their action being alternate and independent of each other. The result is that the middle rod cannot escape except on pressure being applied at both sides simultaneously. It is impossible to open it by pressing on one side only; nor will the fall of a piece of wood, a stone, or other object, effect the disengagement. Pressure on both the olive-shaped ends of the levers, at the same time is necessary to release it; and this can only take place in a kind of funnel, attached to the pit-head, through which the arrangement is drawn when overwound.

Arrangement for Ascent and Descent in Mines.

Herr W. Scharrath, engineer, Berlin, exhibited in the German department a drawing of an ingenious, though perhaps not very practicable method for the convenient ascent and descent of shafts by miners. It consists of an endless chain passing over two large drums with horizontal axis, one fixed at the top of the shaft and the other at the bottom. Between the two chains, and about six feet apart, are fixed platforms capable of holding two men each. These platforms are kept in position, both above and below, by short chains attached to the main

endless chain, and are so arranged as to be always outside the drums when passing over them. This arrangement is quite independent of the cages. The shaft is, therefore, divided into three compartments, throughout its depth, by two partitions. The principal compartment—that in the middle—serves for the cages, while the endless chain passes through the smaller compartments at each side.

Mining Outlook in Montana.

As mining is yet the chief industry of Montana, it is a subject that possesses more interest to the average citizen than any other; still but few, outside of their respective localities, have any very clearly defined idea of what developments are actually being made throughout the Territory. As there are no new discoveries in placer mines, the usual amount of gold only will be taken out, and if any increase is perceptible over the yield of last year, it may be attributed to the fact that the mining season opened 20 or 30 days earlier than usual.

In the Stemple district, Lewis and Clarke county, about 20 men are said to be taking out gold ore and running arrastras, while a number are engaged in erecting a 10-stamp mill, which will soon be in readiness. Those who are thoroughly posted predict that between this time and the first of December, when winter will cause a suspension of crushing machinery, \$50,000 will be taken out. The quartz is of such uniform quality that a certain number of tons will yield a certain amount of bullion. For quality of ore and ease of extraction these mines are the best that are opened in the Territory, and will continue to increase in production as more machinery is attainable, for there appears to be no indications that the supply of ore will not increase more rapidly than increased machinery is erected. It presents one of the best fields for capitalists to erect machinery that can be found in Montana.

The mines in Jefferson county, within a radius of 10 miles of Jefferson City, are being worked with a great deal of energy, and the developments show the lodes to be better and richer than has heretofore been believed. Several hundred men are constantly employed about the reduction works, teaming and extracting ore from the mines. It promises to be, if not the first, at least the second silver district in the Territory within the next two years.

Pony district, Madison county, is taking a leading position for the extent and value of its gold ores. Some 40 stamps are pounding away on rock that averages \$25 per ton. Several hundred men are employed in mining and milling these ores, and the number will be considerably increased as more machinery is erected. All the developments give encouragement of permanency, and the lodes are not less rich as greater depth is attained.

In the Vipond district, Beaverhead county, there is considerable activity manifested in the development of lodes, and there is a large quantity of high grade silver ores extracted. A mill on the Big Hole river, a few miles distant, is the only machinery employed to reduce the ores of that district, but it is understood other works will be in operation before the close of the season, when those mines will rank among the most productive in the Territory.

Butte district, Deer Lodge county, is assuming an importance rarely witnessed of late years. The mines seem to be permanent and they are unquestionably very rich. Three mills, a concentrator and several arrastras are the present reduction facilities, but it is asserted that several other reduction works will be in operation before the close of the year. A large number of men find remunerative employment at the mills and mines, and there is a great deal being done in the direction of the development of lodes that have as yet cut no figure as bullion producers.

At Bannack, Beaverhead county, a number of mills are running constantly with the most satisfactory results, and considerable ore is being taken out of the mines in that vicinity for reduction at home or for shipment to Salt Lake. At Glendale, in the same county, there are reduction works of considerable capacity, which turn out a large quantity of silver bullion. A furnace will also be run at Argenta this summer, on ores from the surrounding mines.

The above are the principal camps that are now turning out bullion, though it is possible that Phillipsburg will shortly be adding considerably to the bullion product of the Territory, while Cable, Radersburg, and the Brandon districts, will help to swell the amount. From this showing it will be seen that quartz mining in Montana is rapidly assuming very important features, and that in the near future the flow of bullion from the Territory will be equal to those of any other of the gold and silver regions, save California and Nevada.

A FRENCH authority according to the *Polytechnic Review*, recommends the use of sawdust instead of hair in mortar to prevent its peeling off. His own house, exposed to prolonged storms on the sea coast, had patches of mortar to be renewed every spring, and after trying without effect a number of substitutes, he found sawdust perfectly satisfactory. It was thoroughly dried and sifted through an ordinary grain sieve to remove the larger particles. The mortar was made by mixing one part cement, two lime, two sawdust, and five sharp sand, the sawdust being first well mixed dry with the cement and sand.

Quartz Mining.

A correspondent of the *Eureka Sentinel* writes the following practical suggestions:

The quartz silver mining question of this camp, and all other camps in the State of Nevada, is a subject of paramount importance to the mining interest. Failures in quartz silver mining are so frequent that many intelligent men who have traveled through the different mining camps of eastern Nevada have left us with an impression that no prudent man should engage in it. Occasional success, no matter how brilliant, is not enough to make an occupation a proper one for men generally. Those who command large capital, and can afford to lose the expense of opening a mine, building a mill or furnace are comparatively rare, and if the quartz mining of the future should be no better than that of the past, and if all should manage the business hereafter as the majority have managed heretofore, then none, save very wealthy men, should engage in it. We presume that there would be no exaggeration in saying that one-half the quartz mills in the State have been unprofitable, and caused serious losses to their owners. The Lemon mill, for instance, in this camp, rotting away because it is not used and of no value to its owners.

But after admitting all that can be said against quartz mining, we still claim that it is one of the best occupations in the world, and that it is capable of immense development, and the great civilizer, for without mining, men would only exist as barbarians. It needs, however, to be conducted on proper principles, otherwise it is extremely dangerous. More than any other business, it needs a well-educated and practical intelligence in the Superintendent, who understands everything about a lode. It is not enough to have a diploma as mining engineer; in addition to the training of the school he needs, above all, experience in the neighborhood, and, if possible, in the very mine where he is at work. General knowledge of geology is of very little use, and proficiency in Latin and Greek are of none at all. If the mines come to a fault, and the ore to a sudden end, the Superintendent should know in which direction the lode has been thrown and how to find it. Such a Superintendent, who should himself be interested in the mine, is the first requirement for safe lode mining. Many mines have succeeded without it, but twice as many might have succeeded with it. The capable Superintendent having been found, he will be very careful about spending the money intrusted to him. He will not presume that every quartz reef contains gold and silver, nor that a claim containing good ore in another lode is rich in his, nor that the occurrence of a rich specimen is a proof of a large deposit of pay ore. He will satisfy himself that he has found a prospect that will pay before incurring much expense, and if he finds neither silver or gold at the surface he will be skeptical about finding it further down. The safe method of procedure is not to build a mill or furnace until there is enough good ore in sight to leave a net profit sufficient to pay for it. There are many mines in Eureka district that will pay on these principles but they have not been properly worked. The many failures have discouraged their owners through the empirics who have been sent here to superintend them. It is almost as dangerous to engage in silver quartz mining as in the higher branches of chemical manufacture without proper knowledge, but with this, the prizes offered are splendid in both occupations.

Rocky District, Utah.

A correspondent of the *Salt Lake Tribune* says: For a long time it has been supposed that in Rocky district, 12 miles north of this place, there would be found a big copper mine of great value. The same has now been found, and the lucky finders are M. Sarault, Dan Severan and M. Atherton. These parties have kept steady at work and at last have been rewarded by the finding of a large body of copper ore that will assay over 50 per cent. copper, eight ounces silver, and about 20 per cent. iron. A new shaft is now being sunk to facilitate the extraction of the ores.

Leonard and Lyon are also developing some copper claims that are looking well, at Beaver Lake district, adjoining Rocky.

There is a rumor that parties in Salt Lake intend to erect a copper smelter in close proximity to these mines. Those who have visited the camp speak encouragingly of it.

In consequence of stormy weather (for it has stormed here for the last seven days) making the roads bad, two of the smelters have been obliged to shut down for the want of charcoal; but this trouble will be of short duration, there being plenty of ore in sight to smelt.

There is now a big stock of bullion lying on the dump of the Shumar smelter awaiting shipment north.

The Wasco and the Hoosier Boy mines are looking well, and improving every day.

PETRIFIED OAK.—Ashburne & Baker, whose hydraulic claims are at Scott's Flat, run across a great curiosity a short time since. After washing down to the depth of about 100 feet from the surface, they uncovered a petrified oak tree, which, by actual measurement, was 43 feet long and six feet through. It is said to be the largest and prettiest piece of petrification ever uncovered in that part of the country. The finest we have ever seen, of all shades shapes and colors, came from diggings in that part of the county.—*Nevada Transcript*.

Field for Prospecting.

We feel that too much attention cannot be called to this county as an excellent field for prospectors. Almost all mining experts who have come here of late, declare we have the richest mining county in the State, and most of our people are convinced of it. Since the pleasant weather began a large amount of prospecting is carried on, and, in fact, an unusual amount has been done on new as well as old ledges during the past year. This is the most favorable season of the year for prospecting either for quartz or gravel, and all who are idle would do well to go out on the hills and try to strike something that will pay. There is an immense amount of ground in the various districts of the county yet unprospected, and one man has as good a chance of making a "ten strike" as another. In the older mining districts of the county there are undoubtedly rich spots and unopened claims which need enterprise and industry, backed with capital to open them, and our merchants and men of means should lend a helping hand in having them thoroughly prospected. Every dollar and every hour's work spent in the development of the mineral resources of the county will result in the ultimate benefit of the county and the parties engaged in it. Some claim there is no certainty of making a strike, but in this respect other vocations are not much better than mining. Every business enterprise, and not a single exception can be named, is but an experiment, in which men venture money, in the hope, without a certainty, of getting it back. The farmer who sows his grain, and the merchant who buys a stock of goods, makes ventures which may result in success or failure. Crops fail and stocks of goods become invaluable, and in almost all kinds of business there is uncertainty. The prospector who finds his gravel pans out well, or who strikes a ledge, giving evidence of richness, takes no more chances in making it than men often do in other kinds of business. Every kind of industry requires earnest labor, constant attention and a knowledge of work to carry it on. With these requisites in view, give the miner a pick and shovel and turn him loose in this county and he will certainly make a living, and be more likely to get a fortune than in any other business.—*Nevada Transcript*.

Quenching Thirst.

Nearly 100 years ago, says *Hall's Journal*, Dr. Lind suggested to Captain Kennedy, that thirst might be quenched at sea, by dipping the clothing in salt water, and putting it on without wringing. Subsequently the Captain, on being cast away, had an opportunity of making the experiment. With great difficulty, he succeeded in persuading a part of the men to follow his example, and they all survived; while the four who refused and drank salt water, became delirious, and died. In addition to putting on the clothes while wet, night and morning, they may be wetted while on, two or three times during the day. Captain Kennedy goes on to say, "after these operations, we uniformly found that the violent drought went off, and the parched tongue was cured in a few minutes after bathing and washing our clothes, while we found ourselves as much refreshed, as if we had received some actual nourishment."

The bare possibility of the truth of the statement, makes it a humanity for any paper to give it a wide publicity, since there are few readers in any hundred, who may not go to sea and be shipwrecked.

We personally know that wading in water quenches thirst, and very few readers can remember being thirsty while bathing at the sea shore, or while swimming in our rivers. When the fearful horrors of dying with thirst are remembered, and the more fearful madness which is the certain result of drinking sea water to allay thirst, it is certainly well to encourage individual experiment in this direction, and solicit an authenticated report of the same.

CONCENTRATIONS AT DRY VALLEY.—Through the courtesy of J. R. Duff, Superintendent of the Meadow Valley mine and mill, we were enabled to pay a visit, on Thursday last, to Dry Valley, for the purpose of observing the process of concentrating the tailings belonging to that mill, which is now being done by Osborne and other concentrators. The advantage derived from concentrating is that the value of seven or eight tons of tailings may be reduced so that one ton will contain the entire valuation of the seven or eight tons, thereby saving enormous freights, if they have to be shipped for reduction, and also the saving of so much cost per ton in working. The process consists in having streams of water running through a portion of the tailings, a constant agitation being kept up, so that the heavy metallic portion falls to the bottom, whilst the refuse matter floats off. This agitation is kept up until, as we stated before, the seven or eight tons are reduced to one. At the Dry Valley mill about ten men are engaged at this process, shoveling, washing, etc. These concentrations have been shipped to Sacramento, Milford, York, Utah, and Salt Lake City, to see at which place they can be worked to the best advantage. Shipments are at present slow, owing to so few Mormon teams now coming to Pioche, the consequence of which is that about 130 tons of the concentrations are now at the mill awaiting shipment. These concentrations work \$120 per ton in silver, in addition to which there is 45 per cent of lead.—*Pioche Record*.

An Important Enterprise.

We have before alluded, says the *Eureka Sentinel*, to the Prospect Mountain tunnel as one of the most important enterprises ever inaugurated in eastern Nevada, if not on the Pacific coast. The tunnel is designed to pierce the very heart of Prospect mountain, at a depth of about 1,600 feet. The tunnel starts at the west base of the mountain and runs nearly due east. Its length, to reach a point immediately under the apex of the mountain, is estimated at 3,000 feet. A number of veins, however, will be cut long before this point is reached. Along the western declivity of the mountain, a great many lodes are known to exist, and it is not unlikely that others, which do not show an outcrop, will be cut. Work in the tunnel has been steadily prosecuted for some months, and the present contractors are said to be making excellent progress. The rock has been unfavorable, but a change for the better, we have no doubt, will soon take place. Within 100 feet from the present face, the Tyndall lode will be tapped, and thenceforward other ledges will be encountered at short intervals, straight ahead to the summit. One authority estimates 15 well-defined veins in direct line of the tunnel. Some of these are owned by other parties, but the tunnel location covers a vast area of mineral-bearing territory, the right to which is undisputed. There is some talk, on the part of those directly interested, of a grand consolidation of all the interests and claims pertaining to that particular portion of the mountain, and there is hardly a doubt that such an arrangement will sooner or later be consummated. This once accomplished, and the Prospect Mountain tunnel would become one of the most valuable properties of which we have any knowledge, in this section of the State. The old mountain has never been more than scratched on the surface, and still it has yielded, in a small way, it is true, a constant stream of the highest grade ore found anywhere in Eureka district. There is hardly a spot 100 yards square, on the whole mountain, where ore of good quality does not blossom to the surface. We all know that ore is not rained down from above—it must put out from below. Hence, the conclusion is irresistible that Prospect mountain, at a proper depth, is one vast storehouse of precious metals. It is to demonstrate this fact that the tunnel under notice is being run. The company is a local organization, composed of sixteen gentlemen, residents of Eureka. It is among the possibilities that Congressman Wren and Mr. Ricord, Superintendent of the Richmond, both members of the tunnel company directory, will, when matters are further along, make an effort to place the control of the property in the hands of English capitalists, visiting London for that purpose. The stockholders in the tunnel have the most unbounded faith in the great value of their enterprise, and whether or not extraneous aid is interested in the work, they are firmly resolved to prosecute operations until the very heart of the grand old mountain shall have been penetrated.

BLASTING BY ELECTRICITY.—The North Consolidated Virginia mining company have of late been using electricity to discharge the blasts put into the bottom of the shaft. This has been attended with the very best results. By this process all the blasts have been discharged at once and several times as much rock torn up as was loosened when the blasts were discharged in the usual way. The process is simple. The battery is placed in the drift above and wires descend to the bottom of the shaft. These wires are connected with the explosives by smaller wires and the circuit thus completed. A few turns of the battery sends the electric spark through the wires, exploding the detonators, which in turn set off the blasts and all at once. Superintendent Jackson reports the effects more than twice as great as when the blasts are discharged by the usual method. The company have sent below for a heavier battery which will be up in a few days.—*Virginia Enterprise*.

WARD DISTRICT.—The *Reflex* says: During the past week the affairs of the Martin White company have engrossed the attention of every one hereabouts to the exclusion of every other topic. The excitement incident thereto has about died out and a feeling of confidence has taken the place of doubt. That company's financial troubles are now at an end, and there is no room for a well founded belief that like embarrassments will soon confront the company again. Advice last evening set even the most shaky at rest. On the whole, Ward district has not suffered from what has occurred, but has been benefited thereby. The worst is over, the panicky rumors of the past week and a half only serving to bring this mining section prominently before the public.

CUPEL FURNACE FOR WARD.—The *Ward Reflex* says: We learn from undoubted authority that it is the purpose of the new management of the Martin White company to erect a cupel furnace immediately, and that it will be ready within thirty days. After its erection only fine bullion will be shipped, which will go through Wells, Fargo & Co. from that time on. Everything that is presented below in the shape of checks is being paid. Nothing more could be reasonably desired. The entire new Board of Directors are reported to be men of unlimited means, and we have every reason to believe measures will be taken looking to the energetic working of this company's mines.

USEFUL INFORMATION.

Hints for House Cleaners.

A lady drawing from a long experience in house cleaning arts has prepared an article for the *Prairie Farmer*. We select therefrom a number of hints which we believe will be useful to many readers:

Soot falling on the carpet from open chimneys, or carelessly handled stove pipes, if covered thickly with salt, can be brushed up without damage to the carpet.

A little spirits of turpentine added to the water with which floors are washed will prevent the ravages of moths.

When carpets are well-cleaned, sprinkle with salt and fold; when laid, strew with slightly moistened bran, before sweeping; this with the salt will freshen them wonderfully.

Fuller's earth mixed to a stiff paste, with cold water, spread on the carpet, covered with brown paper, will, in a day or two remove grease spots; a second application may be necessary.

Spirits of ammonia, diluted with water, if applied with a sponge or flannel cloth to discolored spots in carpets or garments will often restore the color.

A paste made of whiting and benzine will clean marble, and one made of whiting and chloride of soda, spread and left to dry (in the sun if possible) on the marble will remove spots. Paint splashed upon window glass can be easily removed by the application of a hot solution of soda.

Use kerosene and bath brick, or powdered lime to scour zinc, tin, or copper; wash in hot suds, and polish with dry whiting.

To give glass great brilliancy wash with a damp sponge, dipped in spirits, then dust with powdered blue or whiting (tied in a thin muslin bag) and polish with chamois skin.

A flannel cloth dipped into warm soapsuds, then into whiting, and applied to paint, will instantly remove all grease and dirt. Wash with clean water and dry; the most delicate paint will not be injured, and will look like new.

One pound of copperas dissolved in one quart of boiling water will destroy foul smells. Powdered borax scattered in their haunts will disperse cockroaches.

Plaster of paris mixed with gum arabic water makes an excellent white cement, but must be used immediately as it hardens quickly. A mixture of five parts gelatine to one of acid chromate of lime, applied to broken edges, which should be pressed together and exposed to the sunlight, makes an insoluble cement.

To whiten walls, scrape off all old whitewash, and wash the walls with a solution of two ounces white vitrol to four gallons of water. Soak one-fourth pound off-white glue in water for 12 hours; drain and place in a tin pail, cover with fresh water, and set the pail in a kettle of boiling water. When melted, stir into the glue eight pounds of whiting, and water enough to make as thick as common whitewash. Apply evenly with a good brush; if the walls are very yellow, blue the water slightly by squeezing in it a flannel bag in which is some powdered blue.

To clean matting, wash with a solution of one pint of salt to four gallons of water and wipe dry immediately.

To clean oil-cloths, wash always with warm milk. Once in six months scrub with hot soapsuds, dry thoroughly, and apply a coat of varnish. They will last as long again.

A little kerosene added to stove polish improves the luster. Apply while the iron is warm.

To remove spots from furniture take four ounces vinegar, two ounces sweet oil, one ounce turpentine; mix and apply with a flannel cloth.

Gum camphor wrapped in paper and laid around sugar barrels will disperse ants.

Practical Hints about Gas Burners.

Most people who have experimented upon their gas burners at all, says the *Polytechnic Review*, have tried the plan of fitting over the burner a small additional tip. This tip soon grows hot, and a larger flame with more light is obtained. It has been argued, however, that the additional light thus obtained was chiefly due to the more rapid flow of the heated gas, and thus there was no economy attained. The experiments of Dr. Carl Huemann, detailed in *Liebig's Annalen*, will start anew a discussion on this subject. He upholds the old idea that the light of the flame is usually contributed by solid, not gaseous particles of carbon. This is in opposition to the views recently enunciated by Dr. Frankland. If the combustible matter be diluted with inferior gases, Dr. Huemann says, it will require greater heat to make it luminous. A practical feature in his researches is the declaration that light is notably diminished by the use of metallic burners. The substitution of non-conducting material, such as stearite, for the ordinary iron burner, is advised. By raising the temperature of the issuing gas, and of the burner, a marked increase of light was obtained, and this, it is positively stated, was done without a greater flow of the gas. The highest results were attained when the burner was heated close to the orifice. But Dr. Huemann insists that extra heat for the burner must not be contributed by the luminous flame

itself. He declines to enter into the economical question as to whether heating the gas and thus obtaining brighter light, is or is not a profitable operation.

CLOTHES PINS.—The *Newark Advertiser* says: Insignificant as the common wooden clothes pin is itself, its manufacture forms no mean part in American industries, and the numerous factories in New England and other States furnish employment to thousands of people. There are several large clothes pin manufactories in Pennsylvania and Ohio, and one in the vicinity of Saratoga, N. Y., each of which is capable of turning out 1,000 boxes, or 72,000 pins, per week. There are several small factories scattered throughout Massachusetts, New Hampshire and Vermont, and all are run by water power. As a rule, those engaged in the manufacture of clothes pins are Quakers. Beech, white birch and poplar are the woods used in making the article, the birch and poplar being considered the best. The machinery employed is very simple. The wood is first sawed into logs four feet in length, and then cut into small square sticks by means of a cutting machine. Each stick, after being rounded in a lathe, is passed into another machine which throws out a number of perfectly formed pins at one cut and with great rapidity. The pins are then thrown into a large revolving cylinder and smoothed by friction with each other.

STOPPING ADVERTISEMENTS.—We have frequently received letters from readers asking whether such and such a "firm, which recently advertised in the *Press* has suspended," and we know that advertisers do not always consult their best interests by removing their names from before the people. We believe that the following from the *Engineer* is very true: "Certain firms try to economize by taking out their advertisements occasionally; they might as well take down the sign over their doors. Advertisements should be continuous. Any idea of discontinuing them for a period, however brief, with a view of saving, is a mistake which leads only to disappointment and loss. It involves not only the loss of time during which the advertisement ceases to appear, but the additional loss of time required to bring the public interest up to the point at which it left off. The proverb 'out of sight out of mind' is nowhere more applicable than in the case of an advertisement."

GOOD HEALTH.

The School-Room Evil.

[Written for the *Press* by C. L. ANDERSON, M. D.]

The dangers that lurk in the school-room to the breathing organs, and through them to the health of the body generally, I fear, are not sufficiently appreciated. School architects, teachers and the public are, in most cases, almost entirely ignorant of what takes place in nearly all school-rooms where many children are crowded together for hours at a time.

When we consider that not less than one-half the deaths in San Francisco during the past two years were caused by diseases of the respiratory organs, and that this, notwithstanding the epidemic of diphtheria, is not a higher per cent. than occurs in other large cities, we must see the importance of pure air in regard to health.

My attention has been more particularly called to the subject by having charge of the ventilating arrangements of a 12-room school-house.

Take 50 children and place them in a school-room, with doors and windows almost or quite closed, however large it may be and with the ordinary means of ventilation, and but a few minutes would elapse before the air would be impure and unhealthy to breathe.

By ordinary means of ventilation, I mean an opening in the ceiling, windows down at the top, a transom over a door opening into a hall, and perhaps a stove. All these are well enough for certain purposes, but with the exception of the stove, they do but little in the way of removing the most objectionable results of respiration—the carbonic acid gas. This being so much heavier than the air, falls to the floor, and with 50 pairs of lungs manufacturing all the time, it becomes uncomfortably abundant in a little while. Opening the doors or windows at the bottom gives it a chance to escape, but then the pupils are endangered by cold drafts, and they suffer with cold feet, caused by the cold air at the bottom of the room. How shall these things be remedied?

After a year's trial of our school-rooms, we find them to work with much satisfaction. The most usual evil, bad, cold air at the floor and lower part of the rooms, by this system of ventilation, is easily remedied. The plan adopted is as follows: We have two chimneys, consisting each of six smoke flues and six air flues. They are built so that each room has a separate flue for carrying off the smoke and one for ventilation. The ventilating flue is connected with a large air-tight, tin tube under the floor, passing across to the side opposite the place where the stove stands, and opening into the room through

the base-board, with a register, which can be opened or closed at pleasure. Each chimney-stack, containing the flues, is carried straight up from the basement to the top of the building, and high enough to give a good, strong draft. The flues all unite as soon as possible after passing the upper set of rooms. Hence, it will be seen, that a draft, started by heat in either flue, will move the column of air in all the flues; provided they are open. When it is cool enough to have fire in one or all the rooms, the ventilation takes place in this way: The air at the bottom of each room is gently moving towards the register and the opening of the stove and passing into the flues. The room is being swept, as it were, of the cold and the vitiated air, while fresh air comes in through windows or other openings, which may be provided with screens, to prevent a draft. The register being situated at the opposite part of the room from the stove, tends to diffuse the air across the floor, which is being warmed by the stove, thus warming the feet of the pupils.

In warm weather, when there is no fire in either stove and it is desirable to keep the air pure in the rooms, a lamp, placed in one of the flues, would be sufficient to produce a motion of the air. But usually, in warm weather, the doors and windows are kept open, so that there is but little danger of bad air.

The plan above indicated can be applied to any school-house with one or many rooms. The principle is easily understood and the application non-expensive. The chimney is used as a ventilator, and carries that air, which falls by its gravity, out of the room by the force of the heated current set in motion by the air flue. The tube under the floor, opening into the room opposite the place where heat introduced serves two purposes—removing the carbonic acid gas and aiding to diffuse the heat in that part of the room where it is most needed, along the surface of the floor.

In most school-rooms, as well as other public places of meeting, there is no way to ventilate the lower part of the room. The heated air rises and goes out at the ventilators, and if there are openings at the surface of the floor and registers there, as I have seen, instead of carrying out the air that has been breathed, they introduce a current of cold air, because they are not connected with a flue, which may, by heating, give an upward current, and thus pump out the foul air.

There is a great deal of confusion in the popular mind in regard to ventilation and a great deal of nonsense written on the subject. "Patent ventilators" abound, but I believe with Leeds, who has written a very sensible book on this subject, "that perhaps the very best patent that could be obtained for anything connected with this subject would be the application of a little common sense to the use of our ordinary contrivances."

This subject is not so difficult to understand or put in practice. The air of the school-room should be studied and understood by the teacher. If it cannot be kept pure and healthy inside, it would be better to march out and teach in some neighboring grove, after the manner of Plato or Aristotle.

A large per cent. of the diseases that either prove fatal in early years or follow us through life, especially those of the respiratory organs, are contracted in the school-room. This assertion is verified by recent investigations, and is, unfortunately, too true to be contradicted. A reform is needed in the manner of treating our children in schools. It is bad enough for grown people to endure for an hour or two, once or twice a week, the bad air of our halls and churches, without killing off our young children by confinement, four to six hours every day, in badly ventilated school-rooms.

Dyspepsia and Long Life.

The late Dr. W. W. Hall, formerly editor of the *Journal of Health*, has written very sensibly of dyspepsia in a little book just published in New York City by R. Worthington. According to this writer, nine out of every 10 cases of dyspepsia are caused not by any defect of the digestive organs, but by improper dieting and insufficient exercise, mental or physical. People, whom a disordered digestion requires to pay attention to these matters, frequently outlive by many years their more robust neighbors. The author cites the case of one poor dyspeptic patient in whose case no less than 63 ailments were manifested; among them fretfulness, nightmare, and, most dismal of all, a sense of gloom. This was undoubtedly a very bad case, for, in spite of all that wealth could supply, or careful treatment do to remove the disorder, it remained unabated, until finally the offending article of diet was discovered, and then recovery was rapid. In about a month's time the only trouble this restored dyspeptic had to complain of was that she could never get enough to eat. With this instance before his eyes, the most desperate dyspeptic may hope to live cheerfully to a ripe old age by searching out the cause of his troubles and resolutely applying himself to the removal of it.

Dr. Hall recommends the sufferer to begin by eating a little of one or two articles of food at regular meals. If that agrees with him let him increase the quantity; if not he should try something else. In this way the dyspeptic will soon find out what agrees with him, and what kinds of food he should avoid. After he has made these discoveries, it will be his own fault if he continues a dyspeptic.

W. B. EWER..... SENIOR EDITOR.

DEWEY & CO., Publishers.

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTION IN ADVANCE—Postage paid—one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by registered letters or P. O. orders at our risk.

WRITE FOR THE MINING AND SCIENTIFIC PRESS. We invite not only professional men, but practical miners and mechanics to contribute to our columns. All communications will be kindly treated. Authors, as well as readers, will be benefited by corresponding.

Address all letters to the firm, and not to individuals, members, or others, who may at any time be absent from our office.

Our latest forms go to press on Thursday evening.

SAN FRANCISCO:

Saturday Morning, May 19, 1877.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Knight's Improved Water Wheel, 305. Map of the Murchie Mining Property, Nevada County, Cal. 312.
GENERAL EDITORIALS.—Notices of Recent Patents; The Knight Water Wheel; The Crown Point Investigation, 305. Creditable Enterprise; Remedy the Abuses; Mining Stocks; The California Mill, 212. Our Resurrected Mines; Items of Interest From the Mines; How Whips are Made, 213. Patents and Inventions, 316.

CORRESPONDENCE.—Mining Items from Siskiyou County, 306.

MECHANICAL PROGRESS.—Science and Practice in Building; Improved Manufacture of Saws; Wire Working; Industry in South Australia; Brains in American Machines; Iron and Steel from the Ore; Steam Power; Progress of American Manufactures; Life of Cornish Machinery, 307.

SCIENTIFIC PROGRESS.—The Physical Condition of Jupiter and Saturn; Determination of Iodine by the Blow-pipe; Electrical Experiment; The Dog Star; Coal in Alabama; The Gastric Fluid; The Power in Nature; Sugar Making; Prize for a Method of Detecting Adulterations of Butter, 307.

MINING SUMMARY from the various counties in California, Nevada, Arizona, Montana, New Mexico, Utah and Oregon, 309-16.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments, Meetings and Dividends; Review of the Stock Market for the Week, 308.

USEFUL INFORMATION.—Hints for House Cleaners; Practical Hints about Gas Burners, 311.

GOOD HEALTH.—The School-Room Evil; Dyspepsia and Long Life, 311.

GENERAL NEWS ITEMS on page 316 and other pages.

MISCELLANEOUS.—Prospects of Eureka District; Milling Improvements; Wet Treatment of Silicate Ores; Uniting Iron and Steel, 306. New Safety Appliance for Mine Cages; Mining Outlook in Montana; Quartz Mining; Rocky District, Utah; Petrified Oak; Field for Prospecting; Quenching Thirst; Concentrations at Dry Valley, 310. An Important Enterprise; Blasting by Electricity; Ward District; Cannel Furnace for Ward, 311. Growth of the English Navy; The Santa Rita Furnace, 314.

NEW ADVERTISEMENTS.

Machinery, A. L. Fish & Co., S. F.; Rand's Rock Drill, Rand and Waring Drill and Compressor Co., New York; The Statistcian, L. P. McCarthy, S. F. Sales—California and Arizona M. Co.; Mariposa Land and Mining Co. Postponement.—Dolores Con. Land.

A RICH FIND.—The Placer *Argus* says, for a long time past A. O. Bell, who lives near Rock creek, about three miles from Auburn, has been prospecting on various quartz ledges, but with very meagre success. About four weeks ago he began sinking a shaft on a ledge known as the "Life Preserver," which paid well from the commencement, and has increased all the way down. The shaft is now about 30 feet deep. From Monday morning till Wednesday noon he took out, it is estimated, between \$30,000 and \$40,000, \$7,000 of which was taken out in an hour. This statement is corroborated by parties who have seen it. The ledge is about one foot in thickness, and is mostly decomposed rock. The mine is now shut down and well guarded. One small specimen, worth about \$400, is on exhibition at the bank. Mr. Bell on Wednesday sold his mine for \$20,000 to some parties from Inyo county. There is considerable excitement and all the vicinity is being taken up.

WAR MAP.—We have received a very handsome large map of the seat of war in Europe; and also on the same sheet a general map of Europe, with statistics of the military, naval strength, population and financial condition of the contending powers. The map is in colors and very plainly printed in good style. Copies can be had for 50 cents, post-paid, by sending to E. M. Slater, agent for the Pacific coast, 5294 Shotwell street, San Francisco. The map is published by Gaylord Watson.

THE Sulphur Bank quicksilver mine, of Lake county, turned out 1,056 flasks of quicksilver during April.

THE shipbuilders' lock-out, Glasgow, will affect from 25,000 to 30,000 men.

Remedy the Abuses.

There is no doubt in the least that in order to revive the confidence of the public in mining ventures there must be a severe series of reforms instituted, which will clear the business of its worst features and leave it in such a shape that people can enter into it with at least as much chance of making something as in any other undertaking. Just now our largest mines are under a cloud, and in fact all enterprises, the stock of which is sold at the Boards, are in a depressed state. Confidence has been lost in the business, and even the brokers themselves have concluded that reform is necessary.

The committee appointed by the members of the Board to investigate the cause of the depression in the workings of mine management, or whatever in that direction they mean to investigate, need not look very far. They can begin with some of the most flagrant abuses, and afterwards take the lesser ones and weed them all out. Until this is done we hardly need to look for better times in the stock market. Reform is needed more than new bonanzas to create any interest.

The business of milling ore is one of the first things demanding investigation. The prices charged the company, and those actually paid by the managers, might be compared occasionally to the benefit of stockholders. The propriety of Trustees of a company ordering worthless ore sent to the mills, which they own personally, might be considered. Also the question of ownership of tailings. These few subjects will do to start with before taking up the abuses in connection with other points of mine management, or with transactions among brokers which savor of injustice, or worse.

The system by which certain men get control of a mine at the annual election, with the sole purpose of getting a chance to have the ore milled during the year where they want it, is common and well known. They are the Trustees of the stockholders, managing the property in trust for them. Yet, in the face of this, they order ore milled which will not pay the expenses, and levy assessments on the stock to pay the balance. The profits of the milling go to their individual pockets. There is nothing new in this. It is well known and understood, but no one with the power has taken active steps to stop it. Here is a flagrant abuse of trust, and a good place to begin reform.

The question may properly be asked, in what respect do the paid officers of a mining company differ from the servant or agent of any commercial business? Has a President, Superintendent, or Trustee any right to derive profit from a company of which he is a servant? Have the officers any right to profit from the supplies furnished to mine or mill? Have they a right to send the ore to a mill in which they are interested, when they know that in justice to stockholders of the company this should not be done? These questions should be asked in a court of law, and asked of those who have committed these very acts. The people who act as agents and betray their trusts, should be made to answer for their misdeeds before a criminal court, and be punished to the limit of the law. Let this be done once only, and a precedent established, and this great abuse is at an end.

Then the tailings subject comes up. Have the people who are paid to crush the ore, any right to the tailings? If they have, this right(?) should cease, as it is only a premium offered for carelessness, waste and neglect, instead of for economy.

If those mill men who claim such right think they have it, we suggest that they consult some of the most able lawyers of this or any other state, when it is probable their minds will be disabused. If we refer to the annual reports of some of the Washoe mines prior to 1870, say Gould & Curry, Savage, Ophir, etc., it may be seen that the management exercised control over their tailings and slimes, the account being credited with the amount derived from their sale. Lots of these tailings are worth \$50 per ton, and there they lie, near the mills, becoming the property of the mill owners, simply because they put the rock through at so much per ton for other parties. This is all wrong and is the root of a great deal of wrong doing. It should be stopped summarily, and now is a good time to do it. We hope that the Crown Point company who are sufferers in this direction, as the proceedings of the meeting given in another column show, will be the first to direct special attention to it through the courts. Mill work should be let by contract and no Superintendent should have the power to send a lot of worthless rock to be milled because he does not like to see the mills belonging to his friends idle. There are plenty of other abuses to remedy, but these referred to, if stopped, would help stop others as well.

CON. VIRGINIA disbursed, on Monday, \$1,080,000, being her thirty-third dividend, and making a total of \$28,080,000 paid out by the company to the stockholders. In addition to this amount, the mine has earned millions of dollars for working expenses.

ON Wednesday night an extensive conflagration occurred at New Almaden. Eleven houses were burned down; none belonging to the company. Loss about \$5,000.

Mining Stocks.

The depression which has for so long existed in the mining share market has been attended with rather disastrous results to the mining community, and to those who made a living by the fluctuations in prices from day to day. The latter class is numerous, and no doubt much suffering has been felt, but in such a precarious business people must take it as it comes, good or bad, and those who have been imprudent enough to invest everything they had, without putting anything aside for a rainy day, have no one to blame but themselves. Dealing in stocks is hazardous at all times, and poor men have no business at all to meddle with it; for a break such as has occurred, and such as is liable to happen at any time, may impoverish them, while the man with money may hold on and tide over the depression so as to regain his losses. But even men of means are frequently embarrassed and overwhelmed financially by an unlucky turn in the market. This more often happens, however, when they try to take more than they can carry. Rich people can, of course, afford to try their fortunes in the share market with a few odd thousands, but poor ones should let it severely alone. Half of the people who invest in mining shares know nothing whatever about the mines which the shares represent, and care nothing about them either, as long as they can make a turn on their investment in the market. This system is all wrong, and the longer it is kept up the worse it will be for the legitimate mining interests of the coast.

The principle of incorporating mining companies and having shares is an excellent one in itself, and had it not been for this plan the developments made on many of our big mines would never have occurred, for the simple reason that it takes combined capital to do such work on a large scale; and capital which can afford to wait until considerable money and time have been expended. It is the abuses of the system that want remedying, these abuses having continued so long that the public are disgusted and have almost concluded to let the mining business alone for evermore.

Originally, the idea of incorporating mining companies and selling stock, was with the intention of combining capital and for developing mines. This idea has, in many cases, and with many persons, been entirely lost sight of and the whole thing has been perverted into a kind of gambling business, injurious alike to the mining and general prosperity of the coast. Dealing in mining shares is by no means mining, although so considered by some. The majority of those having anything to do with stocks deal in them with the idea of making money from the fluctuations, and care nothing about the mines whatever, except so far as the condition of any particular mine affects the price of the stock. As we have previously stated this is an entire perversion of the whole system of incorporations and shares, but so thoroughly has the practice become rooted among us that it is difficult to make the public understand there was ever any other intention. The mines are considered more as a medium with which to make stock than anything else and they are a second consideration, the shares being the first.

The present depression may be considered a result of a feeling that has for a long time been dormant, that is, that the present system is good for the rich, but bad for the poor. Moreover, that many of the mines are worked for no other purpose than to give certain persons an opportunity to manipulate the stock, and that such mines—and there are many of them—have absorbed more money than their merits warrant. The abuses of the system are more numerous than we have space to detail here, and the sooner they are remedied the better for the public and the mining interests. Our people should learn to recognize the fact that if they have money to invest in mining they should put it into legitimate enterprises and leave the delusions and dangers of the stock market to those who are, like the gambler, willing to risk everything for a chance to make a fortune in a minute. This is not often done in legitimate work, any more than in any other business, although the profits are more likely to be large. If the present panic in the stock market has the effect of putting out of sight forever such stocks as represent mines which are selling for five times their value, it will be a good thing for the country, even if temporary embarrassment to a few is the result. Inflation in anything is bad, and when, because half a dozen mines in one locality turn out rich, the hundred others double or treble their market value, with nothing else to make them do it, the result in the end will be always disastrous. Some of the mines called on our stock boards are notoriously stock jobbing ventures, and no pretensions are made to do much legitimate work upon them; still they are held at prices higher than many legitimate mines upon which real mining is being done. The state of the market just now is very depressing on all classes of business, but if it has the effect of clearing out stock jobbing ventures from legitimate mines, as it appears to be doing, it will be better for the mining business in the end.

WARD district has had a pay-day, the first in some time, and now the people of the new camp are happy.

The California Mill.

The lumber and planing mill interests of this city are quite extensive, as all the lumber that comes here comes in a rough state and has to be planed, sawed or otherwise finished to suit requirements. There are several of these mills in town, all of which have, as a general thing, as much work as they can attend to. The largest and most complete of these mills is the California, on the corner of Spear and Howard streets, the premises of the mill covering upwards of a quarter of the large block. This mill is one of the oldest established, and although running for over nine years, has had the good fortune to escape any damages by fire—that great bug-bear of institutions of this kind. A change has just been made in the proprietorship of the mills by the admission into the firm of Mr. A. I. Sanborn, of Sanborn & Byrnes, stair builders, the whole now being one concern. The firm now consists of C. J. Prescott, A. I. Sanborn and D. W. Ross.

These mills are extensively and substantially fitted out with the best machinery for all classes of work, such as sawing, planing, scroll sawing and turning, stair building, mouldings, sash, blinds, doors, frames and shutters, and wood finish of every description. A walk through the mill shows a hive of industry and gives one a good idea of the perfection attained in the department of wood-working machinery. There are machines for doing every imaginable thing with wood and doing it quickly and perfectly, only requiring the attendance of a man to feed it and keep it supplied.

They have two Gray & Woods and two Woodbury moulding machines, as well as a small molder on the lower floor, there being 10 molding machines altogether in the mill. Some of these machines are capable of making unusually large moldings. There are four band-saws and 10 circular saws in the mill, and also a large and a small sash saw. There is one large upright saw for ship-timber, capable of doing very heavy work. This is the only large saw of this kind on the coast, large band saws for this purpose are found not to answer so well. The Gray & Woods planer on the lower floor is the largest in San Francisco. It is 100 feet long and will take a stick of timber 24 by 32 inches. Among other machinery are half a dozen cut-off saws and as many more scroll saws; a buzz planer for smoothing off small work; variety molding machines or shapers, mortising and tenoning machines; blind and sash stickers; a sand-papery machine for smoothing off fine work, etc.

There are over 200 men connected with this mill at present. The large and heavy work is done on the lower floor in the main building, and the material is then taken up stairs for lighter work. The mill is noted for its ship work particularly, doing about three-quarters of the ship work done here, as a specialty is made of this department. They have recently finished the work of the steamer *Newark*, lately launched. The machinery in the mill is all of the latest patterns and is kept in first-class order. Ship work has to be done in the best manner, and is, as a usual thing very heavy. Everything has to be kept in the best order to turn out this work rapidly, quickly, and of the best material.

The various departments of the mill are under the charge of foremen who have charge of their particular work. P. R. Cunningham is general superintendent; B. L. McDonald is foreman of the machinery department; Mr. Payson of stair-building; John Dickson is foreman of the building department; the carvers are Warren and McKinnon; C. L. Thomas is engineer.

The engine driving the machinery has a 19-inch cylinder, three-foot stroke, with a Myer's variable cut-off. The fly wheel is 18 feet and the driving pulley 16, with an eight and a half inch shaft. Prescott, Scott & Co. built the engine originally, and overhauled it again last year, enlarging the cylinder and putting in new valve gear. The boiler is fed by an Adams steam pump, a California invention which has been running for years, and gives good satisfaction. The engine is about 125-horse power. There are two boilers, 16 feet by 32 inches. In connection with the engine room is a forge at which Geo. S. Fitzgerald, the mill-wright, assisted by the engineer, makes all the molding irons and blacksmith jobbing for the whole mill. This work has to be done with great care, and this little forge saves a good many dollars to the mill owners.

BULLION SHIPMENTS.—Since our last issue shipments of bullion from prominent mines have been as follows: Tybo Con., May 8th, \$11,434.20—total to date, \$22,519.20; Grand Prize, 7th, \$7,060.35; Modoc, 23d bars, value \$6,296.50—total to date, \$25,341.10; Northern Belle, 8th, \$8,133.57; Northern Belle, 11th, \$10,001.52; California, 12th, \$161,378.98—total to date, \$391,544.68; Con. Virginia, 11th, \$190,229.04—total to date for April account, \$1,142,043.66; Grand Prize, 10th, \$6,500; 13th, \$6,700; Leopard, 11th, \$6,000; Indian Queen, 8th, \$1,246.65; Tybo Con., 12th, \$11,414.85—total to date, \$33,934.03; Comanche, 12th, \$10,806.05; Modoc, 13th, \$12,810.73—total to date, \$44,578.33; Grand Prize, 12th, \$6,679.35; Leopard, 11th, \$6,130.

BULLION amounting to \$9,301.61 arrived in Pioche from Leeds during the last week.

Our Resurrected Mines.

Restoration of the Old Murchie Estate.

We have had occasion frequently of late to refer to the greater, and steadily increasing attraction, that is being paid to the various branches of mining in California. There have been seasons of greater excitement, times when speculation ran higher, and when more activity has been manifested in regard to particular kinds of metallic or mineral deposits, but never a time in this State when well-proven gold mines, or such as promised to fairly reward the investment of capital, were so much sought after as at present. In the early history of the State we had our mining excitements, accompanied by a rush of population to the particular point of attraction, wherever that might happen to be; those furies then having occurred with something like periodical regularity. Then came the several excitements about coal, silver, petroleum, borax, and quicksilver, in the pursuit of which the same hurrying to and fro ensued, and the same mistakes were committed as had characterized these earlier movements; our home mines having in the meantime been neglected. After the disappointment that so generally attended these scampering away after these "Jack-o-lanterns," our miners, prospectors, ore millers and moneyed men are coming back to the quartz and placer mines of California, under the impression that they afford better field for the permanent investment of capital and the employment of labor than any offered elsewhere on the coast.

These classes are not now looking so much after a big, as a sure and lasting thing. Bonanzas are of course good in their way, but it has been found a difficult thing to make two or three of these go round, and a considerable number of small mines are wanted for the outsiders. And this is what our mining men are looking for now, as men seek for a farm, or a stock range, or a suitable place for embarking in any other staid pursuit or small industry requiring care and economy; so, with some such idea are they now looking after mines in this State.

One great advantage attending the ownership of mines in California is the fact that parties interested can, as a general thing, easily reach and inspect such properties themselves, and thus be able to better appreciate their exact situation and value, and also judge whether they are being managed properly or not.

With this greater attention now being directed to the gold mines of California, many old properties of this class upon which work had been suspended, or which, through a lack of a thoroughly energetic management, had fallen into a state of decadence, have lately changed hands in whole or in part, and are now again under full headway, or about ready to resume operations. Conspicuous among this number of regenerated enterprises is

The Murchie Property.

Lying a mile or so east of Nevada City, California, a map of which we herewith publish, this being among the earliest mines opened in that well known locality. This estate is remarkable as presenting a good example of the several kinds of gold mining now being prosecuted in California; hydraulic, drift and quartz operations being all actively and profitably carried on within its limits.

The Quartz Mines.

As will be seen by reference to the map, six quartz lodes have been developed on this claim, all being, according to the report of J. S. Phillips not long since made upon this property, strong and well defined, varying from one to eight feet in width, every one of them highly charged with gold, and occurring in a geological formation the most favorable in nature for persistent and affluent veins. Mr. Phillips' endorsement is good authority for the value of this feature of the property. The Big Blue lode has an average width of about four feet and stands nearly vertical; the Independent is twenty inches wide and dips west at an angle of about forty degrees; the Alice Bell ranges from six feet to two feet in thickness with a northerly dip of sixty degrees; the Indian Hill has the same dip and averages three feet; the Red White and Blue is from one to two feet wide, and like the Lone Star, three feet wide, lies much flatter than the others.

In the Way of Exploratory Work

Five shafts have been sunk and three tunnels driven on this series of veins. On the Independent vein, two incline shafts, one 300 and the other 380 feet in depth, have been put down. From Deer creek a drain tunnel, in good part completed, is being driven to intersect these shafts near the bottom. A tunnel, 480 feet long, designed for gravel washing, has been run on the Alice Bell ledge, which in its course has cut the Lone Star, developing there a large shute of high grade ore. The positions of the other excavations made, also of the mill already erected, and the various other improvements, including roads, reservoirs, etc., are indicated on the map, together with the course of the ancient gravel channel that traverses this ground, the working pits opened thereon, etc.

Expenditures, Income and Improvements.

Upon this estate there has, to date, been expended fully \$100,000 in the construction of improvements; all, with the exception of the hoisting works destroyed by fire several years ago, now in good condition and available for working purposes. Among these improvements, apart from the exploratory work already alluded

to, is an eight-stamp mill with all the necessary appurtenances. This mill is driven by water from the company's ditches while the water season lasts, and by steam power the balance of the time; a steam engine of sufficient capacity having been provided for the purpose. The machinery for an additional ten-stamp mill of the most improved pattern has been placed on the ground, and will be ready for operation inside of a month. The hydraulic claim has been thoroughly opened and provided with suitable outfit; iron pipe, derricks, giants, flumes, etc., having been supplied, and a long, bed-rock tunnel constructed for receiving and carrying off the tailings. The company owns two ditches which deliver upon their ground about 500 inches of water from four to five months in the year, the site of this water being secured by perpetual franchise.

Their ground, which comprises 439 acres, held under a United States patent, is heavily timbered with forests suitable for making first-class lumber. The gravel deposit here occupies the bed of one of the old buried rivers, which never fail to prove rich in gold, the small amount of gravel already run off having yielded largely. On the ground are comfortable residences for workmen, outhouses and shops, with tools, cars and implements of every kind needed.

Touching the Former Product of this Ground Scarcely an approximate estimate can be made, the various ravines that traverse it, as well as the bed of Deer creek, having been noted for their prolific outcrop of gold. The Murchie family, who were once exclusive and are still part

Items of Interest from the Mines.

We give below items of interest from prominent mines, most of which are collated from letters of the respective Superintendents on file at the offices in this city:

A slight and unimportant cave occurred in the ore chamber of the 400-ft level of the Justice. Not a pound of ore is lost and no unusual expense incurred in placing the ore-producing stopes in a better working condition.

Advices from the Eureka Consolidated state that the mine is looking much better this week, with very encouraging prospects of soon being able to start a furnace on ore from ground not in dispute. The 5th level drift and upraise from same are now in ore of good grade and carrying a good percentage of lead.

The various ore stopes on the 1500, 1550 and 1600-foot levels of the California are looking very favorable. Those of the 1550 and 1600 are of great width, and the ore is continuous from the northern to the southern boundary.

The Alps is turning out 15 tons of ore per week, that works about \$80 per ton.

Savage is still struggling with a heavy flow of water.

The stopes in the Grand Prize continue to yield the usual amount of high-grade ore.

They have commenced sinking the south winze from the 2135-foot level of the Consolidated Imperial.

Chollar ore samples assay \$24.50 per ton.

MAP OF THE MURCHIE MINING PROPERTY, NEVADA COUNTY, CAL.

owners of it, have alone taken from the quartz lodes and surface diggings enough to have made them independently rich, had they not adventured their means in a too great variety of undertakings. From the Independent mine, they had extracted, up to the time of the burning of the hoisting works, upwards of \$77,000, with considerable sums from their hydraulic claim and other of their quartz lodes. With the burning of these works, which occurred just when they had got their mines in good shape for large and profitable production, active operations were suspended, and so remained until a small company of capitalists and business men, taking an interest in the estate, advanced enough money to put it into good shape; a work that has now been so nearly accomplished that we may expect that this long-neglected property will soon come to the front and liberally reward the old owners for their pluck in holding on, and the new for their enterprise in placing it once more on its feet.

The other day the miners employed by the Boulder Valley coal company, Colorado, struck. The company refused to accede to the demand of the miners and employed new men, who were about to go to work. This so enraged the old hands that they broke into the powder house, stole 20 kegs of powder, blew up the shaft and stoping, and burned the buildings, doing damage to the extent of \$10,000.

The California mill, which has been running on Con. Virginia ore for the past 30 days, cleaned up on Tuesday of last week. Tons worked, 8,600; net yield, \$861,878; about one-half gold. Average per ton, \$101.

The Winfield mill is crushing 40 tons of Ophir ore per day.

Some of the richest ore ever found in the mine was struck in the Comanche last week. It is only in bunches so far.

CREDITABLE ENTERPRISE.—We are pleased to notice the opening of a new restaurant in this city, which, from the knowledge we have of the owner and his qualifications for good and generous providing, we doubt not will quickly take the lead among the city institutions of its kind. The location is 218 Sansome street, between California and Pine, and is central and accessible. The proprietor is Mr. J. V. Webster, one of the leading farmers of Alameda county; a man who knows how to produce good things and will place them without stint upon his tables. We had the pleasure of looking through the establishment before the opening, and we never saw anything more conveniently arranged and perfect in all its points than Mr. Webster's enterprise has produced. Everything is new from floor to ceiling. The kitchen is so light and so planned that it must always be fresh and cleanly. We are glad to pronounce the restaurant first-class in every particular, and recommend it to all whom business or pleasure bring to the city. The opening spread was made on Wednesday night of this week. About one hundred gentlemen sat at the tables. Hon. Frank M. Pixley presided. An elegant and artistic supper was served, and the guests were all pleased with the institution and its proprietor. Comments were abundant upon the fine large space which is occupied, and the charming way in which it is furnished with tasteful and useful articles and supplies.

How Whips are Made.

We doubt not that some of our readers have, in their youth, plaited whip-lashes from wood-chuck hides of their own dressing. That was on the "old farm." Now they find it easier to buy than to make their whips, if they have use for them.

Wishing to obtain some facts relating to the making of whips in this city, we visited the factory of the Keystone Whip Company, No. 2,629 Mission street. Here we found the business carried on in all its details by something more than a dozen operatives. The son of the senior member of the firm, himself an accomplished whip-maker, politely showed us about the factory and explained the work going on. The main items of expense in material are rattan and whalebone. The rattan is imported from Batavia and China. The qualities which are too soft, or otherwise unfit for use in whips, are sorted out and sold to the basket-makers. The fine strips which make up the stock of a whip are split out first by hand, and afterwards worked down by drawing them through a shave, which can be gauged. The whalebone is already split when imported from the East. The price of this article has advanced from an average price of about \$2 per pound to about \$7, in consequence of the loss of the whaling fleet last season.

The main part of most whips is composed of nine pieces. The whalebone is in the center, surrounded by the thin strips of rattan, and secured in place by glue. This compound stock is dipped in glue so that every part is permeated by it, and then run through a machine, which winds it with a strong thread from end to end. It is again wound with rope, so that it cannot warp out of shape, and left to dry. A peculiar turning lathe gives a smooth finish and even taper from butt to tip. This valuable machine was made to order, on a new plan, in this city; the owners of the patented machine used in the East refusing to sell a machine to come here, or permit the use of their patterns.

The thread covers are plaited on to the stocks by machines, which are wonders of ingenuity; some carrying as many as 24 spools. Some of the better grades of whips have this cover made of fine gut, prepared from sheep entrails. Sometimes a portion is worked on by hand, and fancy designs in colors, or the owner's name introduced. A great variety of sticks is used for the stiff portion of the stock, many of them being very handsome. The finest come from England, and include the holly and other ornamental woods. The Malacca cane, which grows in the Dutch East Indies, and is imported by way of Germany, is also used largely. The "mounts," or metallic ornaments are also imported.

Fine lashes for stage drivers, teamsters, or tandem whips are plaited out of the best California deer skin, tanned by Messrs. Keaton at their own yard. They contain from four to 24 strands, and are from four to 16 feet long. Horsehide answers for the cheaper grades used by cartmen and others.

Plaiting lashes well can be done only by careful and experienced hands, and is all piece work. Much of it is given out to be done at the homes of the operatives. Some of the best plaiters are women and girls, who earn good wages by working during hours that are not taken up by other duties, and without being exposed to the publicity of a factory. We wish there were more industries of this sort in our midst. The well-known "black-snakes" of the mountain teamsters are also made here from Santa Clara leather. Their quality depends mainly upon the quality of the leather and number of covers sewed on. These last vary from one to five.

Samples of the goods turned out by this company would form a beautiful exhibit, of interest to any one capable of admiring good workmanship. They comprise every style from the regulation whip of the trotting course, four feet eight inches long, up to the longest stage-driver's "persuader," and they vary in price from \$3 per dozen to \$75 each. A gentleman lately had one made here for Foss, the celebrated Calistoga "whip," which cost \$30, and we saw one made for the owner of a tandem at San Jose, which was an elegant piece of work. The company also makes braided rawhide work of many kinds, such as riattas, bridles, hackamores, etc.

In this business California has to compete with the lower wages and water-power of New England. The Keystone company do not attempt to make the lowest class of goods, but intend that what they do send out shall give satisfaction. On the average they employ about 20 hands of both sexes and almost all ages. Several of "our boys" here find a field for usefulness, but it is not found best to have many in the same room.

About 70 dozen whips are turned out per week in these dull times, but as many as 200 dozen per week have been sold in better seasons. The Messrs. S. & J. W. Keaton are English by birth, have followed this business from boyhood up, and are familiar with all its details. They have had their factory running here for about six years.

THE miners in Ward district have come to the conclusion that tunnels are not the best things for the economical working of the mines, and are going in for shaft sinking.

THE Ward Reflex reports a big strike in the Ready Cash mine of that district. The Ready Cash is included in the valuable property of the Steptoe Consolidated.

Growth of the English Navy.

The following complete list of ships, of all classes, launched during the financial year just closed, will on comparison with the statement of vessels removed from the navy list in the same period, prove how far the additions have been in excess of the waste, and will to some extent enable readers to understand why it has been possible to reduce the estimates for 1877-78. The year was opened by the launch of the 12-gun composite corvette, *Turquoise*, from Earle's yard at Hull. She is a vessel of 1,864 tons, with engines of 2,100 horse-power, and cost about £90,000. Then followed the monster iron armor-plated turret-ship *Inflexible*, which was launched at Portsmouth on the 27th of April. She will carry four 80-ton guns in her two turrets, is of 11,406 tons displacement, with engines of 8,000 horse-power, and cost for hull and engines alone £522,000. The weight of the armor she carries is over 3,000 tons. In May, another powerful vessel, the *Temeraire*, was launched at Chatham; she is an iron, armor-plated broadside ship, and will carry four 25-ton and four 18-ton guns; her tonnage is 8,412 tons, horse-power 7,000, and cost of hull and engines £380,000. The weight of armor she carries is nearly 2,100 tons. In August four vessels were added to the fleet, viz., the composite corvettes *Ruby* and *Emerald*, 12 guns, 1,864 tons, and 2,100 horse-power, costing about £90,000 each; the composite sloop, *Osprey*, six guns, 1,124 tons, and 900 horse-power, costing about £60,000; and the iron gunboat *Medina*, 3 guns, 363 tons, and 310 horse-power, costing £10,250. In October six ships were launched, viz., the screw corvette *Bacchante*, 16 guns, 3,932 tons, and 5,250 horse-power, costing £211,000; and the iron gunboats *Sabrina*, *Medway*, *Spey*, *Tees* and *Tay*, of 363 tons, three guns and 310 horse-power, costing £10,250 each. Then followed the iron armor-plated ships *Nelson* and *Northampton*, carrying 12 guns each, of 7,323 tons, and engines of 6,000 horse-power, and costing about £350,000 each. The weight of their armor is 1,500 tons. In December, three 3-gun composite vessels of 774 tons and 750 horse-power were launched, viz., the *Condor*, *Flamingo* and *Griffin*, costing about £93,000 each; since which time there have been launched the *Buryalus*, corvette, of 16 guns, 3,932 tons, and 5,250 horse-power, costing £211,000; the *Iris*, armed steel dispatch vessel, of 10 guns, 3,735 tons, and 7,000 horse-power, costing about £185,000; the composite gun-vessel *Falcon*, of 3 guns, 774 tons, and 750 horse-power, costing some £35,000; the composite gunboats *Firm*, *Forester*, *Foxhound* and *Forward*, of 4 guns, 455 tons, and 360 horse-power, costing about £20,000 each; the torpedo launch *Lightning*, costing about £6,000; and three torpedo mooring steamers and one torpedo lighter, costing altogether about £18,000. There are also due at this date from the hands of the contractors two composite gunboats and three river service gunboats; but, leaving them out of the calculation, the actual additions to the fleet consist of no fewer than 29 vessels of various classes, representing a tonnage of 58,000 tons, and an expenditure of £2,839,000. During the same period, the removals from the strength of the navy have been, the *Octavia*, frigate, of 3,832 tons; *Racer*, sailing-sloop, of 708 tons; *Black Eagle*, paddle yacht, 540 tons; *Lynx*, sloop, 675 tons; *Severn*, frigate, of 3,485 tons; *Virago*, paddle frigate, of 1,590 tons; *Speedwell*, gun-vessel, 570 tons; *Reindeer*, screw sloop, of 1,365 tons; *Pigeon*, gunboat, of 330 tons; *Barrosa* and *Scout*, corvettes, of 2,431 and 2,187 tons respectively; *Star*, gun-vessel, 877 tons; *Adventure*, iron troop-ship of 2,510 tons; and the sloops *Shearwater* and *Gannet*, of 913 and 861 tons respectively. The removal of ineffective vessels has thus amounted to some 22,000 tons, against the 58,000 tons of new ships which have been sent afloat during 1876-77, thus giving a gain on the side of efficiency to the amount of 36,000 tons, of which 34,464 tons are armor-plated ships.—*Iron*.

The Santa Rita Furnace.

The *Coso Mining News* has the following about the new Santa Rita furnace: "We have been watching with considerable eagerness the progress of the work at the Santa Rita furnace, and hoping that when it started it would prove a success. Last Thursday morning the steam whistle called the men to their posts and the furnace was fired up. Every part of the machinery worked to perfection, the only thing in or about the whole works to give any annoyance being a leakage of one of the water tanks. On Thursday morning last we were invited by Mr. Fortune to come down and see them start up. Arriving at the furnace we had the pleasure of meeting with three of the principal men of this company, Messrs. Jose Carrascosa, Caldonio Ortiz and Edouard Gaxiola, who had come up from San Francisco to examine their property and see the furnace start. These are all solid business men and wealthy capitalists, and in a moneyed sense are carrying quite as heavy a load as Flood & O'Brien. Quite a large number of our leading citizens were also present at the inaugural ceremonies of starting this furnace, and after a thorough examination of the works, and being satisfied the slag was running all right, we were all invited up to the office of Mr. Fortune, the Superintendent, where we all drank bumpers to the health of the members of the company and the success of the Santa Rita furnace. At half-past 2 o'clock on Thursday afternoon the first molding of the bars was

commenced, and up to the same hour on Friday (yesterday) an average of 50 bars of bullion for each shift were turned out. Considering that the furnace was started without any lead bullion but entirely upon the ores, we think this may be put down as an extraordinary run. This amount will be very materially increased after the furnace has become thoroughly heated up. The furnace is of only 20 tons capacity, but is all that is desired for testing the ores and prospecting the mine. It is undoubtedly the entering wedge to more extensive operations on the part of this company, as the gentlemen who came up to examine the property and see for themselves expressed themselves as not only entirely satisfied with it, but are highly pleased with the successful management of Mr. Fortune and his active and efficient assistant and book-keeper, J. A. Green. Another gentleman of this company, Mr. J. M. Tinoco, business manager, in San Francisco, had made preparations to accompany this party to Darwin, but unfortunately for him he met with a severe fall, last Sunday evening, while descending his stairway, by which his right arm was broken just above the wrist, consequently he could not come. Mr. Fortune seems to have exercised the best of foresight and good judgment in selecting his employees at the furnace. His chief smelter is considered one of the best on the coast. Following are the names of the principals at the furnace: Chief Smelter, J. Jameson; Night Foreman, T. Shaw; Day Engineer, Jeremiah O'Connor; Night Engineer, James Rawlings. The names of the other workmen we have not obtained, but they are all well posted in their several specialties. Mr. Fortune will, in a day or two, make his first shipment of several tons of rich bullion. We predict a success for the Santa Rita.

The Explorers', Miners' and Metallurgists' Companion.

Comprising a Practical Exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy, Containing 872 Pages and 83 Engravings BY J. S. PHILLIPS, M. E., Of California, a Practical Operator for Thirty-four Years; Explorer, and Resident in the Pacific States and Territories for the past Eight Years.

PRICE—bound in cloth, \$10.50; in leather, \$12. Forwarded by mail for 50c. extra, at the MINING AND SCIENTIFIC PRESS Office, by DEWEY & CO.

WATER TANKS of any capacity made entirely by machinery. Materials the best in use; construction not excelled. Pan Staves, Tubs and Oak Guides for mining purposes a specialty.

WELLS, RUSSELL & CO., Mechanics' Mills, Cor Mission and Fremont Streets.

To Ship and Engine Builders, Steamship Companies, Etc.

A Mechanical Engineer, having an extensive experience in Marine Engineering (especially compound) and Iron Ship Building, also in Steam Engines and Machinery in general, is open for engagement. First-class references.

Address and references can be obtained at office of SCIENTIFIC PRESS.

IMPROVED VERTICAL ENGINE.

Any parties needing STEAM ENGINES, from Four to Ten Horse-Power, will do well to call on me before purchasing elsewhere. Particular attention is called to my improved Feed Pump.

W. H. OHMEN,

Practical Engineer and Machinist.

32 Fremont Street, San Francisco, Cal.

HYATT'S LIFE BALSAM.

As a conqueror of Rheumatism, Gout, Neuralgia, and cure for Scrofula and all diseases arising from impurity of blood, the old and reliable Family Medicine, Hyatt's Life Balsam, stands unequalled, as proven by over 300,000 great cures during the past 30 years. Is a radical vegetable compound of Sarsaparilla, Dock, Guaiacum, etc., and a permanent cure. Sold by all druggists and country grocers. Take nothing else, and if they haven't it we will send by express, boxed, everywhere, at \$1 and \$1.25 per bottle; \$5 and \$6.50 half doz. HYATT & HYATT, 246 Grand street, New York.

WHEN so many poor watches are being sold, it is not too much for us to say that those who buy the New York Watch Company's movements will be sure of a good article at fair prices.

Superior Pianos for the People at Popular Cash Prices.

More than TEN THOUSAND prosperous families on this Coast need Ten Thousand GOLDEN PIANOS to make TEN THOUSAND HOMES MORE PLEASANT AND ATTRACTIVE.

Prices of good Pianos have long been too high. Our people could not afford to buy them. But many will find it not only pleasant but profitable to purchase

The Brilliant and Durable

GOLDEN PIANO

Which we now offer the readers of this paper

At Greatly Reduced Popular Cash Prices.

We Guarantee them to be as represented, of superior tone, finish and durability.

Samples can be seen by calling at this office. We keep no expensive sales-rooms and attendants.

We shall sell none but superior and desirable instruments, but give our customers the benefit of prices far below any before offered on this side of the Continent.

Prices of the Golden Piano:

The Usual Install-Our Reduction Plan Prices. ad Cash Price.

The Golden Piano, \$500 \$350 (UPRIGHT-C.)

The Golden Piano, \$375 \$300 (SQUARE-No. 1.)

The Golden Piano, \$500 \$350 (SQUARE-No. 2.)

The Golden Piano, \$600 \$400 (SQUARE-No. 3.)

The Golden Piano, \$800 \$450 (SQUARE-No. 4.)

We invite our readers who wish to look at Pianos for themselves or friends, for immediate or future purchase, to call and examine our samples.

Those who cannot call will be supplied with further descriptions and recommendations by sending to this office.

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

512 & 518 Washington St., San Francisco.

We would call the special attention of Assayers, Chem-
 ists, Mining Companies, Milling Companies, Prospectors,
 etc., to our large and well adapted stock of

ASSAYERS' MATERIALS

—AND—

Chemical Apparatus,

Having been engaged in furnishing these supplies since
 the first discovery of mines on the Pacific Coast.

Our Gold and Silver Tables, showing the value per
 ounce Troy at different degrees of fineness, and valuable
 tables for calculation of assays in grains and grammes,
 will be sent free upon application.

JOHN TAYLOR & CO.

THOS. PRICE'S

Assay Office and Chemical
Laboratory,

524 Sacramento St., S. F.

Deposits of bullion received, melted into bars, and re-
 turned made in from 24 to 48 hours.

Bullion can be forwarded to this Office from any part of
 the interior by Express, and returns made in the same
 manner.

Careful Analysis made of Ores, Metals, Soils, Waters,
 Industrial Products, Etc. Mines examined and reported
 upon. Consultations on Chemical and Metallurgical
 questions.

Nevada Metallurgical Works,

21 First Street, 3 doors from Market, S. F.

Ores worked by any process.

Ores sampled.

ASSAYING in all its branches.

Analysis of Ores, Minerals, Waters, etc.

WORKING TESTS MADE.

Plans furnished for the most suitable process
 for working Ores.

Special attention paid to Examinations of
 Mines; plans and reports furnished.

Continued from page 309.

depth of 200 feet having, we believe, in no case been attained.

THE WARD BECHER.—Supt. Fulton showed us this week some nice specimens of milling ore from the Ward Beecher on Treasure hill. He is now working a small force of men on the mine, which he will increase as soon as necessary surveys are made. The Superintendent informs us that it is the intention of this company to do vigorous work upon their mines this summer, and we expect soon to hear of important developments in this once famous property.

Arizona.

PROSPECTING.—*Arizona Enterprise*, May 9: The prospecting fever is raging more violently than ever since the work on the Peck was confined to the development of the north tunnel, pending the negotiations for sale. The miners who were thus left unemployed went off prospecting, and new strikes are being made every day. Prospectors have come in from Nevada and California and have infected the mountains and we hear every day of new and in some cases, valuable discoveries. In the Black Hills, about five miles from Spaulding's ranch, on the Agua Fria, some valuable discoveries have been made. Upon the Bonanza lode the different characters of ore are chloride and gray copper, and assays have been made as high as \$1,100. A new district is to be formed and work will soon be commenced in good earnest.

In Turkey Creek district, Cole & Barry have the shaft on the Continental down 50 feet, and have at the bottom of the shaft two feet of rich ore, of which one strata of four or five inches is high-grade chloride and carbonate ore, and occasionally shows native silver. The ground upon the Goodwin, belonging to Messrs. Collier, Master-son & Hatz, has recently been incorporated in San Francisco, under the name of the Goodwin mining company. Kethro Bros., upon the Silver Joe, have some remarkably rich ore, which they are taking out.

In Hassayampa district, Dave Humes and John Whitman are at work upon a rich galena mine, at the mouth of Groom creek, and are taking out good ore.

In Peck district, the Jack on the Green is a new discovery, four miles east of the Peck mine, and the owners are at work sinking upon it and taking out some high-grade ore, of which they have a 10-inch strata.

In the Peck, the work of developing the north tunnel is being vigorously pushed, and the face of the tunnel shows an immense body of high-grade ore.

In Bradshaw district, A. J. Davis has recently made some discoveries, which he has named respectively the Comstock, Ophir and Katie Haywood. They carry some good ore—carbonates and black sulphurates.

W. B. Hopkins arrived in Prescott last Monday from the Humboldt district, bringing ore from his Little Tommie mine, which is down 30 feet, and goes \$100 to the ton in silver and gold.

In the Tip-Top a new strike has been made, and some samples of the body of ore, which has recently been struck, shown to us yesterday, show a marvelous richness.

RICH DISCOVERY.—*Arizona Miner*, May 4: A short time since, Messrs. Jay G. Kelley, Dr. W. E. Day and A. O. Noyes discovered on Lynx creek, six miles from Prescott, a lead, and named it the Zalida. Since that time they have prospected their discovery and have satisfied themselves thoroughly that they have a genuine lead. Assays made by Mr. Kelley, who is a practical assayer, show their ore to be worth all the way from \$2,000 to \$3,000 per ton. They have sunk a shaft several feet on the ledge, which shows a solid body of horn and sulphide silver ore, two feet thick. The ore is permeated with crystallized sulphate of lead, similar to the ore of the famous Peck mine.

RIO VERDE DISTRICT.—I omitted to say that the miners here held a meeting last Saturday, and established the boundaries of the Verde district, as follows: On the east, the Verde river, from Frank Jordan's house to the mouth of Oak creek; thence west to the summit of the mountain, thence along the summit to the crossing of the Chino trail, and thence to starting point. The facilities for working mines are equal to those of any country. There is an abundance of wood and water, and it is close to a farming settlement. These mines are distant from Prescott about 25 miles, and are approached by rail by way of Coyote Holes. Several locations have been made, but there has been no prospecting below the surface, where the rock assays from 60¢ to 10¢, copper, and from \$40 to \$100 in silver per ton, and the indications are that there are immense deposits of this ore.

Montana.

MINING AND MILLING.—*Helena Independent*, May 4: The owners of the Blue Jay lode, in Stemple district, are very busy in taking out ore from their mine. The lode is large and easily worked, and all developments so far made warrant the belief that they have one of the best lodes in the country. We learn that they have just contracted for crushing 100 tons of the ore at \$3 per ton. As there are only 100 tons of the ore at \$3 per ton, they are expected to pay at least \$25 per ton, judging from that heretofore reduced, the boys have the promise of a little pocket money are long. The ten stamp mill now being erected by Vestal & Company, on Upper Silver creek, will be set in motion early next week, but regular crushing will not begin until one week from next Monday.

New Mexico.

MORE SILVER.—New Mexico *Herald*, March 3: Mr. A. V. Adams, of Pueblo Viejo, in the United States, and an extensive strike has been made near Safford, by a Mr. Riggs. The district is named Montezuma. Several locations have been made. To announce a find of silver ore in this country is nothing wonderful. It would, however, be regarded as something remarkable to announce a section of country of any considerable extent in southwestern New Mexico or southeastern Arizona where either copper or lead did not crop out.

Oregon.

ANOTHER STRIKE.—*Oregon Sentinel*, May 9: Capt. Caton informs us that the miners now engaged in working the Beaver creek cinnabar mines have lately made another strike of a ledge about two feet in width and bearing as rich as any yet taken from the mine. They are meeting with splendid success and all parties are jubilant. The word was brought in Monday by Capt. John S. Miller, who came over on that day after grub and some additional tools and mining apparatus. This mine will doubtless prove a "big thing."

THE GRAVE CREEK DITCH.—From Mr. Sam. Bowden, who assisted in the preliminary survey finished last week, we learn that the ditch will be about 17 miles long and will carry 3,000 inches of water. It will supply water to work several thousand acres of ground which has been heretofore unavailable. The gravel beds are from 20 to 100 feet deep and prospect well throughout, three acres in Brimstone gulch, which has been worked several years, yielding about \$100,000. The company is composed wholly of our citizens, is incorporated with a capital stock of \$250,000, in shares of \$1 each, 50,000 of which they propose to throw upon the market at once in an unassessable form, to enable them to complete the enterprise this season. Work on the ditch will be commenced in a few days and it will be opened up as fast as possible. Once completed and it will open up up to the rich spots known to exist in this and Josephine counties, but which are suffered to lie idle merely for want of capital and enterprise.

Utah.

SAN FRANCISCO DISTRICT.—Cor. Salt Lake *Tribune*, May 11: Situated about 50 miles west from Beaver, and 12 miles from Star district, lies this unexplored little town with the biggest mine in Utah, without any exception. The Big Bonanza lies about one mile from the village. The shaft is sunk 150 feet—all the way in good ore. Not a pound of waste rock or dirt has been taken out of the shaft. The ledge is known to be 200 feet wide. Nearly 7,000 tons of ore have been taken out, and one can hardly see where it came from. Nine lineal feet of this ore will

weigh a ton. About 1,500 tons were taken out to make a level for the whim, which rests on a solid foundation of good ore. A mine with 150,000 tons of good ore in sight, and not a sign of waste on the dump, is a curiosity. It will average over \$40 per ton, and is steadily increasing in value. The four gentlemen who own this Big Bonanza—Messrs. Ryan, Calton, Campbell and Byram—have a certain thing of a fortune, and their slow but sure way of developing their prize shows that they are fully aware of the fact. Twelve miners can take out ore faster than two furnaces can reduce it. There is as yet but one smelter running, but another is to be built immediately by Mr. Godbe, of Salt Lake, who has contracted with the owners of the mine for 5,000 tons of ore as a starter. There will, beyond a doubt, be at least six furnaces running on this ore within a year, when of course there will be a good many men employed, but at present there are enough men here to do all that is to be done. The camp has passed through a year of expectations, and only now have the people found out exactly how to reduce the ore. The smelter has shut down for a few days to repair the engine, having just finished a run of 25 days, producing 130 tons of bullion during that time.

PATENTS AND INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

FOR WEEK ENDING MAY 2TH, 1877.

190,408. CUT-OFF VALVE.—F. A. Bishop, Placerville, Cal.
190,434. TYPE DISTRIBUTING MACHINE.—J. M. Howe, S. F.
190,473. TRACE FASTENERS.—C. S. Crittenden, S. F.
190,475. SEWING MACHINES.—W. A. Dawson, S. F.
190,530. SPECTACLES.—G. Yocco, San Jose.
190,552. WASHING MACHINE.—R. Chatterly, S. F.
190,556. SOFA BEDSTEAD.—H. Combes, S. F.
190,560. CAN-OPENER.—L. Cutting, S. F.
190,588. ENVELOPES.—W. S. Hoeding, S. F.

RE-ISSUES.

7,661. LUBRICATOR.—J. Gates, Portland, Oregon.
662,663. LUBRICATOR.—J. Gates, Portland, Oregon.
7,664. WINDOW SCREEN.—R. Hochkofler, (guardian of G. Reed, insane), W. C. Hoagland and J. J. Newsome, Brooklyn, Cal.

—The patents are not ready for delivery by the Patent Office until some 14 days after the date of issue.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

EAST CALIFORNIA M. Co.—May 14th. Location: Nevada. Capital stock, \$10,000. Directors—Daniel Hanlon, F. H. Farley, J. A. Thompson, R. K. Farley, Thos. Knapton, Henry Wolfson and John F. O'Toole.
CUBE SUGAR MACHINE MANUFACTURING CO.—May 15th. Object: To buy letters patent for cube sugar machines and to manufacture and sell cube sugar machines. Directors—L. Hopken, John W. Murch, W. F. R. Schindler, B. Castleman and J. F. Sarander. Capital stock, \$45,000.
ATZTEC G. & S. M. Co.—May 15th. Location: Aztec district, Pima county, Arizona. Capital stock, \$100,000, in 100,000 shares. Directors—Gov. A. K. P. Safford, Rev. T. M. Cunningham, John Haynes, Calvin A. Poage and C. S. Benedict.

Something about Newspapers.

The statistics about newspapers shown in S. M. Pettengill & Co.'s "Newspaper Directory" for 1877, show the Americans to be emphatically a reading people. It conveys a large amount of information about the newspapers of America, interesting to the readers thereof. There are reported in the Directory the names, character (political, agricultural, religious, medical, etc.), and names of publishers of no less than 795 dailies, 79 tri-weeklies, 125 semi-weeklies, 6,606 weeklies, 122 semi-monthlies, 771 monthlies, 16 bi-monthlies and 60 quarterlies, published in the United States and the British American provinces. The Directory shows the number of each of these editions which are published in each State, Territory or province. The book contains 376 pages, and embraces an immense amount of valuable information, showing great labor in its collection and preparation. It gives all necessary facts for an advertiser to know about 8,574 separate publications, while it is also interesting and valuable for the general reader. Pettengill & Co. are the oldest among the leading first-class newspaper advertising agents in the country.

UTILIZING SQUIRREL SKINS.—We have stated before our belief that the great squirrel nuisance may be greatly abated if we can discover some profitable use to which their skins and carcasses can be turned. We propose to keep the subject up until full and complete trial is made of the materials which can be furnished. If some of our readers will send us a dozen or two of squirrel skins, properly stretched and dried, we will put them on exhibition at the Mechanics' fair in this city, then send them to the Paris exhibition of 1878 and try to call the attention of foreign manufacturers to the cheap price at which they can be obtained in endless quantity. Parties who will aid us in making an exhibition of this kind will please send the skins by mail, prepaying the postage at the rate of one cent per ounce, and not cause us to pay express rates, which are much higher. We should like farmers to state at what price they can furnish them by the 100 if wanted. We trust our readers will help us in this matter, that the subject may be fully tested.

SIXTY thousand shares of Knickerbocker stock were purchased for account of the company at the delinquent sale.

THE California mine paid a dividend of \$1,080,000 on Tuesday.

General News Items.

THE flour mill at Salinas City was burned on Saturday last.

THE Russian fleet is in this port, but will soon leave with sealed orders.

THE City of Brussels, supposed to be lost, is all right, she having only broken her shaft.

THE coopers' strike at Cleveland, Ohio, is over, the men having gone to work at the old prices.

It is stated that all persons indicted for complicity in the recently developed insurance frauds in New York will have speedy trial.

WHITNEY, a prominent speculator in mining stocks, reported to have failed in New York, was formerly an operator in San Francisco.

THE Governor has appointed Prof. George Davidson, of San Francisco, a Regent of the State University, vice Felton, deceased.

Two thousand colliers in the Dartmouth district, Prussia, have struck. The strike threatens to assume serious proportions.

VOLUNTEERS from the English militia regiments have been asked for, for hospital and transport service. The Duke of Edinburgh is on his way to the Suez canal.

THE Turkish gunboat which passed Kalafat under cover of the Turkish fire from Widin, was captured by a Roumanian battery lower down the river.

THE time for receiving bids for service on miscellaneous mail routes in Arizona has been extended by order of the Postmaster General, to June 20th, 1877.

THE Tribune says the Stevens battery will soon leave American waters under command of Capt. Samuels, and will be sold to Russia either on the high seas or after arriving at England or France.

THE Tribune's Washington special discredits the newspaper stories of filibusters on Mexico being reinforced by the United States, giving Assistant Secretary of State Seward as authority therefor.

THE Department of State, Saturday, received information from our Minister at Peking that the Chinese Government had given notice that it would, on the 1st of April, open to foreign trade the additional ports of Ichang, Wuhun, Wenchoo and Pakyoo.

PROF. RILEY, Chief of the National Entomological Commission, has just closed a three weeks' examination in Texas and Kansas of grasshoppers, and submitted his report to the Governor. He says that throughout the largest part of Kansas the battle is already fought and won.

It is stated that the reason of William H. Vanderbilt's trip to Europe is the establishment of a line of steamers between New York and Europe. The steamers are to be modeled after the White Star ships, and at first will carry only freight and steerage passengers.

THE Managers of the Chicago, Burlington and Quincy, Missouri, Kansas and Texas, and Texas Central railroads, have effected a fast freight combination of their roads, which will go into operation June 1st, and they will regularly run 200 cars and seven sleepers through from Chicago to Houston and Galveston, Texas, from that date.

THE Standard Oil Company's coopers, Cleveland, Ohio, 1,500 in all, who struck three weeks ago, will return to work on Tuesday at the company's terms, but with the promise as business revives wages will be increased. The company also agrees not to employ boys in their shops, but to give all their work to men.

THE reply of the State Department to the formal notification by Turkey of the existence of a state of war between that power and Russia, is to the effect that the United States will continue to occupy a strictly neutral position towards the belligerents. A similar reply will be furnished to Russia. Boker, Minister to Russia, will return to St. Petersburg the latter part of this month.

THREE new ferry slips are being built directly south from the present landing of the Oakland boats, and will be completed about the 1st of August. The most southerly one will be used by the boats of the Dumbarton route. The other two have not been assigned yet. It is probable that the Oakland boats will change their slips, and arrangements made to avoid the crossing of the different boats in their trips.

THE Porte is uneasy about the supplies of arms and ammunition still to come from New York, and is very angry with America for allowing the Russian squadron to remain in American waters. Bad feelings are increasing. Turkish journals have already advocated the massacre of Christians. The English representative has demanded explanations. Many Turks resent the idea of a friendly occupation of Constantinople by the English, and say if England wants to help Turkey, she should do so on the Danube and in Asia. There is great uneasiness among European residents. Many have left and others are leaving. The Khedive's actions are watched very distrustfully. It is known that he has been previously tempted by the Russians, and it is thought if the Turks suffer any important reverses the temptation will prove too strong for him.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

Questions of the Times.

Which are the most reliable watches?
American watches, they are driving those of foreign make out of the market.

Which is the best American watch?
The New York watch, made at Springfield, Mass.

Why is it the best watch?
Because it is substantial in all its parts, constructed on the best principles and embodies those improvements which experience has shown to be the most desirable.

Why is the New York Watch so popular?
Because in buying one you are sure of getting a good time-keeper. While purchasing a watch of most other makes is like investing in a lottery—a great many blanks to one prize.

Which is the cheapest watch?
The most economical is the New York watch. For you can get one of these excellent time-keepers for less than it costs in a short time to repair a poor watch, which benefits no one but the repairer.

Where can I get a New York Watch?
By addressing the long established, practical Watch-makers and Jewelers, DEWEY & JORDAN, 433 Montgomery St., San Francisco, who will send you a descriptive price list, including the following styles of movements: "John Hancock," "Geo. Sam. Rice," "Chas. E. Hayward," "Aaron Bagg," "Theo. E. Studley," "Chester Woolworth," "Frederick Billings," "Railway," "John L. King," "E. W. Bond."

THE GRAND PACIFIC.—This hotel, well known to all persons from the Pacific Coast who have visited Chicago of late, under the new management is a perfect success. It is well for travelers to remember that at this house, in order to meet the expectation of the public in these times of financial depression, a sliding scale of prices has been arranged, from \$3 to \$5 per day, with board, according to location, the service, table and all other accommodations being the same to all guests. The entire hotel has been re-furnished and decorated, so that it is handsome both externally and internally. All the conveniences and modern improvements for the convenience of the guests are at hand.

PACIFIC RURAL PRESS.

A first-class 16-page Illustrated Agricultural Weekly, filled with fresh, valuable and interesting reading. Every farmer and ruralist should take it. It is immensely popular. Send for a sample copy.

DEWEY & CO., Publishers, S. F.

ORDERS for the GOLDEN PIANO will be received at this office, where further information can be had concerning their excellent qualities and favorable prices.

To Mining Secretaries.

An amendment to Section 336 of the California Code, taking effect July 1st, 1874, provides that in addition to the regular publication, daily or weekly, of the assessment and sale notices as heretofore,

PERSONAL NOTICE

Must be served as provided in the following quotation from the law:

"The notice must be personally served upon each stockholder, or in lieu of personal service, must be sent through the mail, addressed to each stockholder at his place of residence, if known, and if not known, at the place where the principal office of the Corporation is situated."

The above refers to the ASSESSMENT NOTICE only. Advertisers in the MINING AND SCIENTIFIC PRESS will be furnished with copies of assessment notices printed on slips suitable for serving personal notice under this law at short notice.

DEWEY & CO., Publishers.

Mining and Other Companies.

Booth Gold Mining Company.—Location of works, Auburn, Placer county, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the thirtieth day of April, 1877, an assessment, No. 2, of five cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, No. 320 California Street, Room No. 5, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the fourth day of June, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the twenty-fifth day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Directors,

GEO. R. SPINNEY, Secy.

Office, 320 California St., Room 5, San Francisco, Cal.

California and Arizona Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Cedar valley, Mohave county, Arizona.

Notice.—There are delinquent upon the following described stock, on account of assessment No. 2, levied on the third (3d) day of April, 1877, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
Edmund Burch.....	13	50	\$1 00
Edmund Burch.....	15	500	10 00
Edmund Burch.....	17	500	1 00
Edmund Burch.....	18	200	4 00
Edmund Burch.....	19	200	4 00
Edmund Burch.....	21	200	4 00
Edmund Burch.....	24	100	2 00
Benjamin Flint.....	39	4,000	80 00
W H Hall.....	41	2,500	50 00
James W Thrift.....	43	2,500	50 00
E E Rice.....	44	2,500	50 00
E E Jewell, Trustee.....	49	1 49	
Martin Corcoran.....	50	1,250	25 00

And, in accordance with law, and an order of the Board of Directors, made on the third (3d) day of April, 1877, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at Room B, No. 507 Montgomery street, on Monday the fourth (4th) day of June, 1877, at the hour of two (2) o'clock, P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

T. E. JEWELL, Secretary.

Office, 507 Montgomery Street, San Francisco.

California Fruit Growing Association.—Location of principal place of business, San Francisco, California. Location of property, El Dorado county, Cal.

Notice is hereby given that at a meeting of the Board of Directors, held on the 14th day of April, 1877, an assessment, No. 4, of \$2.00 per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary at the office of the company, 331 Sansome Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 21st day of May, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before will be sold on Saturday the 9th day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors,

HORACE JONES, Secretary.

Office, 331 Sansome Street, San Francisco, Cal.

Consolidated Bonanza Silver Mining Co.—Principal place of business San Francisco, California. Location of works in Eagle and Washoe Valley Mining District, Ormsby county, State of Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 19th day of April, A. D. 1877, an assessment, No. 1, of 10 cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary at the office of the company, No. 19 First Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on Tuesday the 29th day of May, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the 19th day of June, 1877, to pay the delinquent assessment together with costs of advertising and expenses of sale. By order of the Board of Directors,

WM. MARTIN, Secretary.

Office No. 19 First Street, San Francisco, Cal.

Dolores Consolidated Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Dolores Mining District, Esmeralda County, Nevada.

Notice.—There are delinquent upon the following described stock, on account of assessment (No. 1) levied on the seventeenth day of February, 1877, the several amounts set opposite the names of the respective shareholders, as follows:

Name.	No. Certificate.	No. Shares.	Amount.
Blasdel, H G, Trustee.....	16	10,000	\$2,000 00
Blasdel, H G, Trustee.....	17	5,000	500 00
Blasdel, H G, Trustee.....	18	5,000	500 00
Blasdel, H G, Trustee.....	19	5,000	500 00
Drexler, L P & Co., Trustee.....	8	25,000	2,500 00
Fry, J D, Trustee.....	7	10,000	1,000 00
Keene, J R, Trustee.....	9	10,000	1,000 00
Talbot, W C.....	3	100	10 00

And in accordance with law and an order of the Board of Directors, made on the seventeenth day of February, 1877, so many shares of each parcel of said stock as may be necessary, will be sold at public auction at the office of said company, on Monday, the sixteenth day of April, 1877, at the hour of two o'clock, P. M. of said day, to pay said delinquent assessments thereon, together with costs of advertising and expenses of the sale.

J. W. CLARK, Secretary.

Office, 418 California street, San Francisco, California.

POSTPONEMENT.—The sale of the above described certificates of stock is postponed from the 16th day of April, 1877, to the 16th day of May, 1877, and will then take place at the same hour and place as above named. By order of the Board of Directors,

J. W. CLARK, Secy.

POSTPONEMENT.—The sale of the above described certificates of stock is postponed from the 16th day of May, 1877, to the 16th day of June, 1877, and will then be held at the same hour and place named above. By order of the Board of Directors,

J. W. CLARK, Secy.

Empire Mining Company.—Location of

principal place of business, San Francisco, California. Location of works, War Eagle Mountain, Owyhee County, Idaho Territory.

Notice is hereby given that at a meeting of the Board of Directors, held on the twenty-sixth day of April, 1877, an assessment, No. 13, of \$1 (one dollar) per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company, No. 330 Pine Street, Room No. 5, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the thirtieth day of May, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before will be sold on Tuesday, the twenty-sixth day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors,

WM. H. MCCLINTOCK, Secy.

Office, 330 Pine Street, Room No. 5, San Francisco, Cal.

Excelsior Silver Mining Company.—Principal place of business, San Francisco, Cal. Location of works, Potosi District, Lincoln County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the twenty-fourth day of April, 1877, an assessment of ten cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold and silver coin, to the Secretary, at the office of the company, 308 Post Street.

Any stock upon which this assessment shall remain unpaid on the twenty-fifth day of May, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the eighteenth day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

W. A. KOLLMYER, Secretary.

Office, 306 Post Street, San Francisco, Cal.

Mariposa Land and Mining Company of California.—Location of principal place of business, San Francisco, California. Location of works, Mariposa County, California.

Notice.—There is delinquent upon the following described stock, on account of assessment, No. 10, levied on the twenty-eighth day of March, 1877, the several amounts set opposite the names of the respective shareholders, as follows:

The Ingersoll Rock Drill

Is Extensively Used in the East and

TAKES THE PLACE OF ALL OTHERS,

Wherever introduced, because it can be run with less power, labor and repairs, and do more work than any other Drill in the market. It has but few parts, is easily handled, being light, and has AUTOMATIC FEED, which saves labor. WE ASK FOR TRIAL AGAINST ANY COMPETITOR. For particular information regarding Drills or Air Compressors, send for circular to

J. B. REYNOLDS,

(Room 10.)

320 Sansome Street

THE O'HARRA

CHLORIDIZING FURNACE

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this Process:

Two cords of wood at \$8.....\$12 00
Two firemen at \$4.....8 00
1,500 lbs of salt at 1¢.....22 50
Wear of shoes and power.....1 50

Cost for 15 tons.....\$44 00
Cost for one ton.....2 93½

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in the Peavine District. For further information, apply to

D. J. O'HARRA,

Reno, Nevada.

Really Important.

Dr. Noon's combined Electro-Magnetic Sudatorium Baths cleanse the system from Lead, Arsenical, Mercurial and other poisons. Will cure Rheumatism, Torpid Liver and Chronic Disorders. Our system is the most effectual in the world, combining with all needed medicines, Hygiene-Oxygen Inhalations, Electric and Hydropathic treatment, all skillfully used as necessary. Often cures where others fail, and always in less time.

Dr. Noon has had much special, practical experience in the treatment of the disorders incidental to mining life. Consultations free.

PATENTED CAST STEEL SHOES AND DIES.

Guaranteed Cheaper than the Best Iron.
IMPORTANT NOTICE.
Reduction in Price from 16 Cents
to 12 Cents Per Pound.

Owing to our largely increased business, the present low price of iron from which our Steel is manufactured, and the improved facilities for casting and forging, we take great pleasure in announcing that from and after this date we will supply our IMPROVED CAST AND FORGED STEEL SHOES AND DIES FOR QUARTZ MILLS at twelve cents per pound, delivered at San Francisco or Sacramento, instead of sixteen cents, as heretofore.

We also furnish Steel Plates for Blake and other Ore Crushers, Steel Gut Gearing, etc., for Mills and Hoisting Works, Steel Pan Shoes, Battery Cams and Tappets, etc., etc.

Address all orders, with dimensions or drawings, to

CAST STEEL SHOE & DIE CO.,

59 Nevada Block, S. F.

TULLOCH'S AUTOMATIC ORE FEEDER,

Awarded the Centennial Medal.

The TULLOCH AUTOMATIC ORE FEEDERS have been practically tested during the last year and a half in 40 mills, of from five to 80 stamps each, and have, in every case, given perfect satisfaction. The Tulloch machine is so constructed that the drop of the stamp feeds the ore in just such quantities as the stamps require. Each drop regulates the supply required for the next drop, whether it be more or less, and this is the true principle of an automatic feeder. The tray moves longitudinally, and a stationary scraper forces the material forward at each backward movement of the tray, thus insuring the perfect feeding of all classes of ore, whether it be dry or wet.

We append a few extracts from the many testimonials which we have received from mill men and practical mining men, of the effectiveness and positive action of the Tulloch Feeder. We do not depend solely upon these testimonials, as we are aware that testimonials are easily secured for almost any machine, but the high character of the parties certifying to those herewith given, will establish their value and genuineness:

Mr. Jas. G. Fair has 28 in use; says: I regard them superior to any Feeder with which I am acquainted; I consider no mill perfect without them. Mr. E. R. Burke, Summer mine, Kern county, has 16: They never get tired; no man living can feed a battery as well; they save us in labor alone \$48 a day. Mr. Green, of the Phoenix mill (13), Amador, writes: The first machine we had is working away; is as good as ever; have not spent a dime on it; in use 14 months; you need fear no competition on wet ores. Mr. W. H. Armstrong, of Consolidated Virginia mill: We are running 60 stamps with your Feeders; they give unbounded satisfaction; they have not cost the company one dollar since starting up. Mr. H. C. Bidwell, Supt. Green Mountain and Gold Stripe companies, Plumas county, writes: From the start they have done splendidly; no trouble whatever; requiring but little attention; a boy can manage them; the saving in both labor and castings is fully one-half over the old style of feeding by hand. Mr. Preston writes: I have four of your Automatic Self Feeders, and my mill men each and all say they are the best they have ever used. They are an improvement on all I have ever seen, being simple in construction, and good for either wet or dry crushing; refer to over 40 mills using them; they are guaranteed to give perfect satisfaction. Send for circulars.

F. OGDEN, 413 California Street, S. F.

PICKERING ENGINE GOVERNOR.

VALLEJO FOUNDRY, October 17th, 1876.

Messrs. NEYLAN & YOUNG, San Francisco,

Agents for "PICKERING GOVERNORS."

Gents:—The 10 two-inch Improved Speed Adjusting Governors I bought of you this year for my patent Straw Burning Engines give splendid satisfaction. They far surpass for regularity of speed any Governor that I have ever seen, and I have seen all the best kinds; I have seen the main belt fly off the pulley several times this season while threshing, and the engineer did not discover it, so perfectly was the speed maintained, until he was told of it; this I consider something wonderful; I consider the Governor absolutely perfect, so far as speed is concerned. I bought and put on to one of my engines a Shive Governor, to see which was the best, and after one season's trial I have no hesitation in saying they are far superior to any other Governor that I have seen or used. I wish you would send me the lowest price that you can furnish 25 Governors for, next season's engines. Yours respectfully, J. L. HEALD.

The only Governor that has received awards at each of the International Exhibitions. American Institute Fair, New York, 1865, Two Medals; Mechanics' Institute Fair, Baltimore, 1865, Silver Medal; American Institute Fair, New York, 1869, Two Medals; International Exposition, Paris, 1867, One Bronze and Two Special Medals; International Exposition, Vienna, 1873, Medal of Progress and Decoration; International Exhibition, Philadelphia, 1876, Medal and Diploma.

Ferris & Miles'
Steam Hammers.

Knowles' Steam Pump; for all purposes where Pumping is required.

Union Rock Drill.

We offer this as the least complicated and most durable Rock Drill yet introduced.

Office of Amazon and Glasgow Mining Co.,
San Francisco, Nov. 25, 1876.

A. L. Fish & Co., Agents for Knowles' Patent Steam Pump,
Gents: After using many devices for pumping mines I must say the DOUBLE ACTING PLUNGER MINING PUMP (Knowles' Patent), bought some time since for the Amazon and Glasgow mines, is seemingly as near perfection as it is possible to be. We carry steam 500 feet to the pump, raising water 400 feet, which it does easily with 40 pounds of steam, without the slightest jar on the pipes, and is perfectly noiseless. Gravel cannot wear the cylinder, and it is by far the simplest, cheapest and most economical way I know of for draining mines. I would cheerfully recommend them. Yours truly,
A. Caldwell, Superintendent.

Number 21.

Academy of Sciences.

The regular meeting of the California Academy of Sciences was held on Monday evening last, President Davidson in the chair. L. C. McAfee, J. C. Sibirian and J. T. Murphy were elected resident members. The contributions to the cabinet were valuable. They included 59 specimens of birds, representing 57 species, collected around San Francisco and Sacramento, by G. L. Lansing, to whom a vote of thanks was passed for his gift. A silicified piece of wood, from Forest Hill, was presented by J. P. Dameron; Prof. Davidson presented a piece of carbonate of magnesia from Fort Point, and another member contributed a fine specimen of the pipe fish.

Prof. Davidson made a communication on earthquake waves, noticed at Fort Point at the Golden Gate, phenomena caused by the earthquake at Iquique. We give elsewhere in this issue the Professor's remarks on this subject, and also a diagram showing the results recorded by the gauge at Fort Point. Prof. Davidson also read a paper on an improvement in the break-circuit chronometer.

W. N. Lockington read a paper on a peculiar description of goby fish, specimens of which were recently found in the sand of Richardson's bay by Mr. Throckmorton. It can remain out of water a long time by means of a special organization adapted to the storage of water.

Mr. Dameron read a paper on the blue gravel auriferous formation of the Sierra in connection with a mortar that he described as prehistoric, found in the deposit. He said that the finding of such prehistoric implements in the gravel is reported to be common, and from this he concluded that the aboriginal flourished while the blue gravel deposit was in process of formation. Prof. Davidson said he did not think the Academy should give its sanction to the statement that the mortar was actually deposited with gravel. It might have got into the gravel in some way, but that might have been during the last 10 years. In a similar way toads have been found in stones and trees at enormous depths.

Dr. Harkness exhibited a specimen of the black knot fungus, *Sphaeria morbosus*, found in the Yosemite valley. This fungus is peculiar to North America, and has heretofore been described as only occurring east of the Rocky mountains. It attacks the cherry tree, and in some districts of the East has almost rendered the cultivation of the cherry impossible.

Dr. A. W. Saxe, of Santa Clara, called attention to a newly discovered parasite that has appeared in his section of country, and has developed into a most alarming pest, attacking fruit trees and ornamental shrubbery. The insect was first observed in September, October and November, 1876, and at that time it was only observed on the acacia rubra, then on the pendula and latifolia, and afterwards on all the acacia; also on rose bushes, and on most of the tender shrubs of the garden, except those that have pungent juices. The doctor exhibited a twig of *Ficus Australis* and a twig of rose tree covered with the pest—a large white insect by some unknown means of locomotion had taken possession of nearly every acacia in town, and all the rose bushes, locust, mesquit and other shrubs. The ova are mostly deposited on the young succulent twigs and the under side of leaves. After depositing its ova, and when full grown, being about half an inch in length, the insect falls to the ground. It is very destructive. In two years it destroys an acacia tree, no matter how large. It also fastens on orange trees, and appears very destructive to them. He had not observed, at any stage, whether the insect be comes winged; but it spreads over a quarter or a half mile in a month, and it has not been ascertained how it travels. The ordinary birds that feed on insects do not feed on this, and avoid the trees on which it has effected a lodgment. It resembles the coccus.

Dr. Harkness stated that similar reports came from San Mateo eight weeks ago. There were millions of them, and the farmers were cutting off the branches and throwing them on the ground.

Dr. Saxe said that there are localities all along the Santa Clara valley where the orange grows luxuriantly, and the insect is quite as destructive to the orange as to the acacia. He had applied

carbolic acid, soap and water, and had kept the insect off the orange tree so far, but it is going to be a very troublesome pest. It is worse than any other form of infesting insect that he has seen.

Improved Washing Appliance.

We herewith illustrate a washing machine which is novel in principle of construction, mode of operation, and in the peculiar adaptability of the material employed to do the work, viz: that of vulcanized india rubber, which the practical working of this machine has shown to be as well suited to the purpose of washing wearing apparel as it is well suited to the purpose of wringing the articles after they have been washed. The rollers in the machine are corrugated, but are differently spaced to create an abrading action when they are revolving. The top roll is covered with a sleeve of vulcanized rubber, prepared expressly for this pur-

DENNEY'S IMPROVED WASHING APPLIANCE.

pose, with cloth inserted to prevent stretching to get loose upon the roll. An endless band of same material revolves with the under roll. It has an inclination outward, and crosses under the machine. The band is perforated to allow a circulation of the suds and air from the channels in the under roll. The elastic force of the confined air drives the suds through the goods, thus cleansing them. The inclination of the band prevents the clothing dropping off when run through past the rolls, and allows the articles to be washed out to the ends. To enter the goods they are pressed against the band, to which they adhere, and are carried in without danger of pinching the fingers.

The advantages possessed by this machine over that of naked wooden rollers will be apparent to every intelligent person. The soft, elastic character of the rubber adapts it to washing all grades of wearing apparel and other domestic goods, from the coarsest to the finest, without possibility of injuring the texture of the finest articles used. Double the spring pressure is applied to the rolls that is applied to wooden rolls, thereby increasing its efficiency. The rubber is specially prepared for the machines. It is almost indestructible, white and attractive in appearance. For any further information concerning the machines, address the inventor, S. I. Denney, Gap, Lancaster county, Pa.

ANOTHER PLACER COUNTY STRIKE.—The Placer *Argus* says that two old miners who have been prospecting in the vicinity of Auburn many years, have at last stumbled upon something that promises to make them independent. About ten days ago they commenced work at a point near the Chinese cemetery, a mile and a half from town, finding good indications from the first. They are now down only fifteen feet, but have taken out rock, three tons of which, not selected, were crushed at the Union Star mill, and yielded \$410, or at the rate of \$136.66 per ton. There is a well defined ledge about two feet in thickness, which it is believed will hold out rich. The rock is not decomposed, like that found by O. A. Bell last week.

THE Virginia *Enterprise* says that during the past three months no less than thirty-five mines have shut down altogether. Of those still working some are not employing more than four or five men.

An Improved Water Filter.

We illustrate on this page an improved filter, recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by G. & W. Snook, which is intended as an attachment to water pipes through which water is conducted under pressure, so that the water can be purified and cleansed for drinking and other purposes. By the means employed the inventor is able to use an open-topped tank as a filtering vessel.

The water is admitted in the pipe, A, passing through the stop-cock, B, and pipe, C, discharging into the lower chamber of the filter. It is then forced up through the filtering material, and may be drawn off at pleasure through the stop-cock, D, connecting with pipes to any part of the house. The supply is regulated by the float, H, attached to the stop-cock, B. To clean the filter, close the stop-cocks, B and D; then open the valve, F, at the bottom of the

overflow pipe, G, when the water will flow down through the filtering materials and out of the valve, F, into the overflow pipe, G, carrying all the impurities with it. If it is desirable to give a more thorough cleaning, open the stop-cock, E, and let the water flow into the upper part of the filter until thoroughly cleansed; then close the stop-cock, E, and valve, F, when it will be ready for use again.

This filter is simple, durable and easily

Snook's Patent Water Filter.

cleaned. It is self-regulating, and, we are assured, will last many years without renewing the filtering material. It is of a capacity to filter all the water required for an ordinary dwelling house, and is a preventive against worms, bugs and all other mechanical impurities in water. They may be connected to any tank, and through the usual pipes supply the whole house, or the water may be used direct from the filter, where no tank is required for other purposes. Several sizes of these appliances are made to suit varied requirements. They are inexpensive, and will be kept in repair free of expense by the patentee. The manufacturers are G. & W. Snook, 427 Pine street, in this city.

THE President has dismissed the charges against Governor Potts of Montana.

An Antiseptic Burial Casket—New Method of Embalming.

Dr. Samuel Rogers, of this city, after having experimented for several years, has made a discovery which is of great interest to science, and to the medical profession in particular; and which is destined to effect an entire change in the present systems of embalming, or preserving the bodies of the dead. All the methods hitherto in vogue, although varying slightly in detail, depended on the injection of preservative chemicals into the veins or arteries. Although this in a measure answered the purpose, it was not entirely successful, as the features were liable to change and discoloration, the method expensive and its success greatly dependent on the skill of the operator.

Dr. Rogers employs for the purpose desired a casket of peculiar construction, and a newly discovered compound with which the body is washed. The casket is made with double walls, or with a recess in the bottom in which the chemicals are placed. After the subject is placed in the casket and the lid is sealed, by drawing out a small valve the chemicals begin slowly to evaporate and their action preserves the body. Before being placed in the casket, the body is washed all over with the solution, and the process has the effect of preserving the body for an indefinite time without its showing any signs at all of decomposition.

During the experiments in this direction by Dr. Rogers, extending over a period of years, the bodies of sheep, dogs, etc., were used, and it is only of late that any attempts with a human body were made; but the result of the experiments with the former leaves no doubt of the success of the process. If there had been any doubts they are removed now by the method having been applied to a subject obtained in a legal way from the city and county hospital, for anatomical purposes.

We examined this subject last week, some 50 days after death; there was no sign of decomposition apparent. There was no odor whatever, and the limbs and joints are as pliable as when in life. The solution applied to the surface of the body passes in by the law of endosmosis, and seems to act upon every part of the body. The flesh appeared moist and natural in color. The viscera had not been removed, as has to be done in ordinary embalming. This subject was preserved under unusual difficulties, as it had been exposed to the action of the air during the entire time since death, as it was necessary to examine it frequently as a matter of experiment.

As will be seen, this discovery is quite simple in the means employed, rapid in the time required, and requires no expert to apply it. The natural appearance is not dried out of the body, nor is it at all mutilated. This subject has been critically examined by several members of the medical faculty of this city, who concur in the expression of their satisfaction at the result of their examination, which was conducted in a thorough manner. Among the physicians alluded to were Dr. Wythe, Professor of Anatomy in the Medical College of the Pacific, Dr. Titus, ex-resident physician of the City and County Hospital, Dr. Albertson, Vice President of the State Homeopathic Society, Dr. Henry Gibbons, Sr., editor of the *Pacific Medical Journal*, and Dr. Parry. Several incisions were made, and it was found that the blood was still as fluid as if the man had only been dead an hour or two, whereas fifty days had elapsed since his decease.

The process is entirely accomplished by the external application of chemicals without injecting the circulatory system, as in ordinary embalming. And still the body is kept in a perfect state of preservation. The process has proven for a period of seven weeks to be perfectly antiseptic in its action, and also a perfect disinfectant in its effects, as there is no odor emanating from the body. For the purpose designed by Dr. Rogers, of preserving bodies for transportation to the East or Europe, this discovery merits the attention of the public and especially of the medical profession. For preparing bodies for anatomical purposes, when not needed for immediate use, the present condition of the body referred to, warrants the assumption that the process keeps them in a better state and is superior to any method practiced in the different medical colleges, as published or now known to anatomists.

The Guadalupe Mine.

"I have traveled many lands, and have seen much of the world's most wonderful and beautiful scenery; but nowhere have I ever beheld so rare a gem as this." Such was the remark of Mr. Hastings, a shrewd Yankee, and a wealthy shipping-merchant of Boston, whom we met at the residence of Col. B. B. Thayer, at the Guadalupe quicksilver mine, in this county, a day or two since. And such, we doubt not, was his honest conviction.

But few of our citizens are probably aware of the remarkable improvements and valuable developments which have been made upon this fine mining property within the last two and a half years—since it passed under the management of the present Superintendent; and but few are doubtless prepared to believe that the sum of \$1,000,000 has been expended upon the property during that period—in the construction of new hoisting and reduction works, store-houses, offices and miner's cabins; in improving and beautifying the grounds, and in the development of the mine.

Brief History of the Mine.

The Guadalupe was among the first of the early cinnabar discoveries of this State. The mine is located in a wild mountain gorge, on the Guadalupe creek, in the Santa Cruz range, near where the creek emerges into the valley, and distant from San Jose about 12 miles. It is about three miles in a straight line from the famous New Almaden quicksilver mine, and is a part of the same great cinnabar formation, which may be traced for hundreds of miles along our Coast range. The mine was discovered as early as 1846, and has been worked with varying results, subject to intervals of litigious suspensions, ever since. It was never, until recently, regarded as a profitable mine—owing, doubtless, to the crude methods of working it, and the lack of experience and capital to develop it properly.

Sixteen years ago the present month, when the editor of this journal visited the mine for the first and (until now) the last time, he found the facilities for working the mine very imperfect. The old incline was located on the right bank of the creek, and terminated near the first level of the present shaft. The furnaces and condensers were of the old styles wasting nearly as much quicksilver as they saved, and requiring vastly more fuel than the present furnaces, which are continuous feeders, and waste positively no metal. The property at that time presented a generally unthrifty appearance.

The title to the property—which is a United States patent—having been settled, and the ownership having undergone some important changes, the work of developing the property was undertaken in earnest. Capt. Mayo, who superintended the mine for a number of years, was succeeded by Capt. Brown, and he, after two years of management, by the present Superintendent, a man well known throughout the State as a chemist, mining expert, and what was of the most consequence, as a thorough-going business man.

The First Step.

Colonel Thayer entered upon his duties in the fall of '74. He saw at once the necessity of confining the creek in a water-tight channel to prevent the flooding of the mine. This was accomplished in a few weeks time with the labor of 500 hands; and thus was one of the most serious obstacles to the successful working of the mine removed. A new shaft was sunk on the opposite side of the creek from the old incline, and hoisting works were erected which can hardly be excelled by anything of the kind on the Comstock. These works alone cost \$150,000. The balance wheel of the mighty engine weighs 22,000 pounds, and other portions of the machinery are of like ponderous character. The structure rests upon the solid rock, and the engine runs with the smoothness and precision of clock work. The main shaft is divided into three compartments, one of which is used for the great pump which drains the mine, and the others for hoisting the ore and lowering timbers, etc., to the mine.

To the Lower Regions.

Stepping upon the cage, in company with Colonel Thayer and his mining Superintendent, Captain Williams, at the top of the bell we were dropped the little matter of 600 feet, or about an eighth of a mile into the bowels of the earth; thence traversing a tunnel for a distance of several hundred feet to the very heart of the mountain, we came to a solid body of ore, which has been uncovered by a cross-cut for a distance of 220 feet. Here we found a perfect wall for the entire length of the ore matter, as distinct and well defined as any which encases a vein of silver-bearing ore. Of the thickness of the ore body no man knoweth; but that it is a veritable Quicksilver Bonanza.

Is beyond question, as the developments already made in the lode have amply demonstrated. It will be some months yet before this body of ore can be worked to advantage, as the main shaft has first to be sunk to a greater depth, and the necessary drifts, winzes, stopes, etc., to be constructed. Then we may confidently expect that the product of this mine, which is now 1,000 flasks of quicksilver per month, will be speedily increased to 2,000 or more flasks. Upon the upper levels are large quantities of ore easy of access, from which

The Furnaces

Are now supplied. Other furnaces are soon to be erected to meet the increasing product of the

mine. Of those recently constructed by Colonel Thayer, they are the result of many years of experience in the reduction of quicksilver ores, and combine the largest reducing capacity with the minimum of expense.

About the furnaces and works generally perfect order everywhere reigns. The men, of whom there are about 250 employed, are provided with comfortable homes. They are of the best class of miners, the good-for-nothings having been sent adrift. All the mining is done by contract, and thus skill and muscle become at once chief factors in swelling the pay roll.—*San Jose Mercury.*

The Bear River Mines.

On Friday last, in accordance with an invitation received and accepted, we paid a visit to the various mines located on Bear river. In the morning we repaired to the *Forum* office and found that our escort, J. W. Ritchie, had engaged places for us in the Foot & Walker line, and started out. After leaving Dutch Flat we struck the Miner's ditch, and followed it. The scenery on this route is grand and picturesque in the extreme, and coupled with the delightful task of walking long flumes, on a six-inch board, renders it the most popular route by which to reach the mines. About dinner time we arrived at the upper ditch camp. The first claim to which we came, and situated below all the others, was the

Ritchie Mine.

This claim is situated about nine miles from Dutch Flat, on Bear river, lying partly in Nevada and Placer counties, and is a drift mine. The claim was located in 1870, by J. W. Ritchie, the present owner, and W. Riddle, who commenced operations at once, and it has been worked ever since. It is 4,000 feet in length, 1,000 in width, and contains 170 acres of ground. The first operations were begun at a point about 140 feet below the west line of the Whipple claim, by running a straight tunnel for 182 feet. On reaching this depth the bed-rock began to dip, when an incline, 126 feet long, was run to the bottom of the channel. From this point a drift was run west, at right angles with the main tunnel, which was in 372 feet. The gravel for the entire length of the drift has paid well, and in some places was very rich. In one of these rich spots \$1,288 were taken out in a short time, and in another, \$500. In 1873 a tunnel was run at the lower end of the claim for 400 feet. This also followed the bed of the channel, which has an average width of 80 feet, and the gravel yielded gold in handsome quantities. In May, 1876, Mr. Ritchie leased a portion of the claim to D. Crissman and Wm. Ballew, who employed two others, and commenced work in both tunnels, running drifts east and west to connect, and thereby procure good air. Mr. Ballew sold out his interest to Wm. Duren. At present there is some little delay in the work, as the air in the lower tunnel is becoming very bad, and they are running straight ahead, so as to connect as soon as possible. The yield of the claim at present averages \$10 per day to the man, with good indications of increasing. Both tunnels are supplied with an overshot wheel, pump and machinery for hoisting and forcing air into them. This claim has paid wages ever since the gravel was struck, and, as stated above, sometimes enormously. The channel on which they are now at work is about 80 feet wide, but there is a large body of gravel, from 50 to 200 feet in depth, and a thousand feet in width, that would yield handsome returns if hydraulized. It has been prospected thoroughly and carries gold from the top to the bedrock. Taking everything into consideration the future prospects of this mine are very bright, only needing energy and perseverance to make it one of the richest mines in Placer county.

The Whipple Mine

Commences at the eastern line of the Ritchie claim, and runs east 800 feet. The claim was located in 1870, by the Whipple Bros. and John Deardoff, but Mr. Deardoff sold out shortly after. They commenced work on the upper part of the claim first, but not meeting with the success they had expected, in 1875 they removed their works to the lower boundary line. They commenced on the channel, running an incline 110 feet in length to the bottom of the channel. They then commenced drifting and have run an easterly drift over 200 feet from the bottom of the incline. The yield from the claim has varied considerably, but at the present time it is yielding very flatteringly. The gold is getting coarser, some nice little pieces having been picked up lately. The works on this mine consist of an overshot wheel, pump and hoisting machinery, all of which are run by water-power. Four men are employed in the mine, and work is being pushed steadily ahead. The body of gravel lying within the boundaries of their ground is not so extensive as the Ritchie deposit, but prospects well from top to bottom, and as a hydraulic mine would pay equally as well as any ground on the river. Next in order we come to the

Dry Creek Company Mine,

Owned by H. Bartlett and others, which was located about the same time as the other mines. The claim extends 2,000 feet along the channel, the belt of surface gravel not having an extensive depth and area. An incline of 101 feet was run to the channel, and a drift was run from this point 500 feet, in which they struck coarse gold. No stoping was done, the drift being run for prospecting purposes only. As

they did not take out much gravel, only prospecting the dirt as they went along, the mine did not pay wages. At present the mine is shut down, but we understand that the proprietors intend to commence work in it shortly. It is their belief that they have the best claim on the river, and they do not intend that it shall lay idle long. They have the best rigging for working the mine on the river, and when they are in full operation we expect to hear of large returns.

The Bonanza Mine

Is the last in the chain of mines that we visited, and is owned by eight citizens of Dutch Flat. The claim contains 160 acres of ground, for which a patent will shortly issue. A tunnel has been run 80 feet, and as far as prospected will pay well for hydraulizing. The proprietors are energetic men, and when the time comes for them to begin operations they will go to work with a will, and if the indications are to be relied on, will have a veritable "bonanza" in their mine.—*Dutch Flat Forum.*

Important Ditch Enterprise.

The Nevada Transcript says: John Cashin, J. S. Thompson, J. D. Sweeny, M. M. Richardson and J. H. Thomson, have filed a document in the County Recorder's office, setting forth that they have located and appropriated fifty thousand inches of water, running in Truckee river, measured under a four-inch pressure. They take it from the river at a point called Camp 20, in this county, at the dam of the "People's Ice Company." The purpose for which this water location is made is to convey the water of the Truckee river in a flume and ditches into Sierra county, in this State, and into Washoe county, in the State of Nevada, for floating wood, timber and lumber, and more particularly for irrigating land. The flume and ditches will extend to Spanish Spring valley, in Washoe county. The flume at the initial point will be constructed twelve feet wide on the bottom and four feet high on the sides, with two and one-half inches grade to the rod, and will be continued on a grade that will be necessary to convey the water to the agricultural lands lying north and south of the line of the flumes and ditches. The ditches and flumes will be of sufficient capacity to carry fifty thousand inches of water to the above named point. They claim the right of way for their flumes and ditches over all lands lying along the line to the points above mentioned. The distance is about thirty miles. We understand the main idea in contemplation of this enterprise is to furnish water for irrigating the lands in that vicinity. There are thousands of acres there that are of no use to anybody in their present state, it being utterly impossible to utilize it without water, and the movement is projected to give it a good and permanent value. The land can now be bought of the Government for \$1.25 per acre, and when the enterprise is carried through it is claimed it will be worth \$5 or \$6, and perhaps more. An illustration of that fact is shown in the case of the inauguration of the same kind of an enterprise between Reno and Steamboat Springs, where, previous to water being carried there in flumes, the land was worthless; but now it commands a high value, from the fact that at that point any kind of feed for animals can be raised upon it. As soon as the company get the matter properly arranged they will commence the building of the flume and ditches. They expect to get at it this season.

River Mining.

What is this new class of mining you call river mining? So query many, and the *Foot-hill Tidings* replies in brief:

Twenty years ago river mining meant turning out a river—such as the Yuba or Feather—from its natural channel, either to a remote bank from the place to be mined or through flumes by the aid of wing dams or otherwise, pumping out the water, and then stripping a few rods square down to the bedrock and washing out the gold from the gravel found therein. Sometimes a company of men would spend an entire summer in getting a spot opened and never get a color before the early rains would drive them out; then again, a delay in the rainy season would enable them to work the spot for some weeks, and many's the pile made in this way. Down on the Yuba, for instance, the Cape Horn, the Grizzly, and many other mining companies, were known to take out from 50 to 100 pounds of gold per day some seasons—and as high as \$800 was washed from single wheelbarrow loads of the gravel taken out. It was only a few years that this kind of work could be done, for the tailings from the mines above came down to such an extent as to preclude the possibility of stripping any more.

Now, after 18 or 20 years of the accumulation of this debris—filling some of the rivers to the depth of 30 to 60 feet with a hard, packed and puddled clay and cement substance, it is proposed to sink down in the bedrock on these river banks, drift under this accumulation of debris and in the usual way of mining out ancient river channels secure the immense deposits of gold known to exist along these river beds.

River mining is soon to be the favorite field of venture for capitalists—this we already feel perfectly assured of—and so soon as the Yuba River company, the pioneer in the work gets in, those who secured interests in river mining while in prospective will be considered lucky *hombres*. Mark our prediction.

Trinity Mining Interests.

The almost total failure of placer mining, says the Trinity Journal, compared with what it would have been had the past season been different, leads us to look around us and see the opportunities which may offer for entering into other kinds of mining than that wholly dependent upon the seasons. The last winter was a peculiarly unfortunate one for the country in more respects than one. It not only produced less gold than the customary amount, but it checked the prosecution of important enterprises, which, had they been carried out as originally projected, would have opened a large field for the employment of labor, and thus paved the way for another era of prosperity. But it may be that the failure of placer mining will be the means of turning the attention of working men to other channels of employment, and be, in the long run, more of a blessing than present appearances would warrant.

The cinnabar mining interests, which commanded great attention two or three years ago, is not, at the present time, prosecuted with that vigor which the importance of the interest would seem to demand. This does not follow as a result of the failure of the lodes heretofore worked, but rather that there is not the demand for quicksilver, nor does that necessary article of commerce command the price in the market at which it was held two years ago. The high price then asked for quicksilver was not in consequence of any scarcity of the article, nor for the reason that, by a probable failure of the mines from which the chief supplies of quicksilver had been drawn, there would be a scarcity in the near future. Quicksilver, like any other article of necessity, was subject to the manipulation of speculators, and in this way, the supply of the market was monopolized and controlled by a ring which placed such a price upon the article that it could not be used with profit in many places where it had heretofore been employed. The fictitious value thus given to quicksilver stimulated prospecting, and thus caused the discovery of many new mines, some of them of value. Foremost among these were the cinnabar mines of this county. While the demand for quicksilver continued, and the price was held at the high figures of two and three years ago, the work of prospecting was prosecuted with energy and resulted in finding indications of the metal in a number of localities near the site of the main discovery. These mines possess a value which the future only can determine. When the present lull in mining in Nevada and elsewhere gives place to renewed activity, it will be followed by an increased demand, and consequent higher price for quicksilver which will justify the holders of claims in developing them to a greater extent.

But it is not to placer, nor yet to cinnabar mining that we are to look for the great source of employment in the future. Each is good in its way, but there is another mining interest which has not, as yet, been fairly started, but which will at some time in the near future, be a prolific source of wealth. We refer to quartz mining. Where there have been such rich and extensive deposits of placer gold as those which built up Weaverville, Junction City, Douglas City, Lewiston, and in fact all our chief mining camps, it stands to reason that there must be veins of paying quartz, from which all this wealth has come. Other counties, such as Amador, Calaveras, Nevada and Tuolumne years ago became noted for the quartz mining which grew up near the site of rich placers. Such, we think, will also be the case in Trinity. Already we hear of developments which were in a great measure unexpected. The existence of a quartz ledge which would hold out such good promise as the Bullychoop, was a thing hardly to be dreamed of three or four years ago. Shares in this ledge now command a fair price which a year ago were, to say the least, of doubtful value. The success of the holders of Bullychoop should inspire others to a search for the veins from which the placers of other places have been enriched.

In one respect the quartz hunter in this county will have a greater difficulty to contend with than has been the case in the placers of the Sierra Nevada range. The bedrock lies at a greater depth from the surface than in the low mountains in which the gold deposits of southern counties were formed. We presume the fact that there have been in past years greater rainfall and consequently a greater growth of vegetation in a measure accounts for this fact. Quartz in granite bedrock is easier traced or found for the reason that the bedrock is nearer the surface than slate is usually found.

Recent discoveries in Deadwood creek show the existence of paying quartz in that locality; the indications of which were noticed in some prospecting done years ago. Deadwood heads up in the mountains opposite French gulch, where rich quartz was worked in former years. There is no good reason why the search for quartz should not be successfully prosecuted in other localities as indeed, is being done to some extent. The existence of quartz veins has been noted in almost every mining camp, but thus far little has been done toward testing and developing them. There are a few of our old resident miners but can recall where the noticed quartz ledges in former days, but thought little or nothing of the matter at the time. It can do no harm and may be of service, if they would give them a little attention now.

MECHANICAL PROGRESS.

Uses for the New Form of Steel.

We made a note recently of the progress in steel manufacture by which cast-steel is being produced cheaply directly from pig-iron, and consequently may be used in heavy castings. This new form of metal is called "solid cast-steel." An English exchange gives a number of instances in which this cast-steel may be used advantageously for forged work in machine parts. It says: "There will be no need to state that the uses to which the metal may be put are exceedingly numerous, when it has been demonstrated that its properties are equal to those of the best forged steel. We make a few remarks on those applications of the metal to machine construction which appear to us to be most important. For heavy shafts, straight and bent, for steam engines of large size appears to us to be the most important application of solid steel to general industry. The forging of ingots of such large dimensions has, up to the present, been a matter of great difficulty. The ingots nearly always contained large cavities arising from agglomeration of the metal on cooling. On the other hand, the operation of hammering ingots of such dimensions is accompanied by serious difficulties, and experience has amply shown the inconvenience of this system. The same rules apply in casting pieces of this kind as have already been detailed; molds will naturally vary according to circumstances. Annealing must always be carried out with the utmost care, and the metal maintained at a red heat during such time as may be requisite for the softening action to have full effect. All these pieces of machinery, like cranks, pinions, shafting, may be constructed with considerable advantage of cast-steel; the quality should be of the very softest, so as to offer a maximum of resistance to shock. They should be cast in ingot molds whenever practicable, as this greatly conduces to the solidity and soundness of the casting."

PORTABLE ELECTRIC LIGHT.—An ingenious little electric light apparatus has been invented by Mr. Facio, of Paris, and is applicable to watches, walking sticks and such like. The watch, for instance, to which it is applied is united by a chain to a link bar, which may be placed in a button hole, another chain communicates with a pile which may be carried in the waistcoat pocket; to the link bar another chain is attached in communication with a receptacle or box containing wick, and a "Geissler" tube, which will transmit the spark produced by the electricity. Thus the time can be easily seen in the dark. The apparatus is composed of other conducting chains coming from the pile, and of a receiver which may be perfectly independent, the receiver being provided with a wick or bobbin, and the receiver may be made like a locket or other article if desired; communication between pile and locket or other article may be produced by means of a button or other suitable appliance placed in any convenient position. The chains may be formed or composed of two wires and surrounded by insulating material, which latter may be covered with some precious metal or other material as fancy or taste may dictate. The lighting material may be carried by the watch itself, or the light generating apparatus may be provided with a case to hold the watch or other object to be lighted up in such a manner that the glass which covers the aforesaid case will receive the action of the lighting tube containing the "Geissler" tube, and the case itself will be independent of the object to be lighted.

GOOD FORGERS.—The question has often been asked us, says the *Carriage Monthly*, "How is it that some smiths are able to make better forgings than others?" or "How is it that— is always so successful with his welds?" The secret of all this is in first knowing how, and after knowing how, in doing, or trying to perform, what we know. The knowing smith so lays out his work at the close of the day that his first work in the morning will be the heaviest and such as requires but little welding. By doing this he not only leaves the lighter portion of his labors for the waning of the day and also the tiring of his arm, but he removes the chill from the anvil and other tools to such an extent as to prevent the iron becoming chilled before the weld is properly made. His fire is always clean. His tool rack is always in order, thus enabling him to grasp the required tool at the proper time. He never places his iron in the fire a second time until, with a file, he has removed all the scales. The ice-cold anvil will chill the thin part of the "scaf," and prevent the welding of that portion. It is impossible to take a clean heat with a fire full of slag. If you have to hunt five minutes for a tool, your iron has become cold, and unless you remove the scales and other matter, your forgings will not be perfect.

SERVICE OF STEEL WHEELS.—The Boston *Advertiser* of April 2d says: "The locomotive *David Tyler*, of the Boston & Providence railroad, has under its tender a set of German cast-steel wheels, made by Bochum. Each wheel has run 102,002 miles, and shows little or no signs of wear. These wheels were imported in 1872 as an experiment."

TESTING RAILROAD MATERIAL.—The *Aurora*, Ill., *Beacon* says that the Chicago, Burlington and Quincy Company require all material of whatever kind, to stand a thorough practical and scientific test before being delivered to the locomotive, car or track depots. All boiler material is tested by bending while cold, which it must do without showing a flaw, and by getting the tensile strength of every sheet. Every sheet of iron for fire-box use must stand a tensile strain of 60,000 pounds per square inch. Every sheet of boiler material not for fire-box use, must stand a strain of 55,000 pounds per square inch. Every sheet of steel for fire-box use must stand a tensile strain of 70,000 pounds per square inch, and no sheets of iron can be issued from the store without being marked "Tested, O. K." All stay-bolt iron must stand 60,000 pounds per square inch, and bend double cold without showing any flaw, and a bolt, three-quarters of an inch in diameter, must bend double cold, with a thread cut on it, without showing cracks more than one-third of an inch in depth. All common bar-iron, whether round or flat, must bend double cold without showing a flaw deeper than one-eighth of an inch, and bend double red-hot without showing any tendency to "red shortness." All flues or boiler tubes must be of maker's weight, not less than No. 13 (wire gauge) in thickness, nor greater than No. 11; must caulk into a flue-sheet without cracking or showing any seams in iron; must flat down and bend double cold without showing any flaw or crack either across or lengthwise of flue, and must show a homogeneous material when subjected to an acid bath.

AN ATMOSPHERIC ENGINE.—A reader of the *Press*, in Indianapolis, Indiana, sends us an account of a new atmospheric gas engine, constructed by Sinker, Davis & Co., of that city, from which we give the following descriptive item: "The engine is vertical, perhaps eight feet to top of fly-wheel, and can be operated in a floor space of four by five feet. Its mechanism appears to be not intricate, compared with the ordinary stationary steam engine. No smokestack is needed. The principle upon which this engine works is as follows: Gas and air, mixed in such proportions as to give a mild explosive compound, are admitted under a piston, which slides air-tight in a vertical cylinder, open at the top. The compound is ignited, explodes, and the explosion drives the piston upward. The ignited gases, having increased in volume, lose their heat; their pressure becomes less as the piston rises, and when it has reached the top of the cylinder, a partial vacuum is formed, and the pressure of the atmosphere makes the piston descend. The work thus done steadily by the atmosphere during the return stroke of the piston, yields the driving power, which is transferred to the shaft by suitable mechanism. The utilization of the instantaneous power of the explosion, by allowing the piston to fly up freely from it without doing other work than emptying the cylinder of air, is the basis of the great economy and success of these engines."

BOX PILING FOR SMALL SCRAP.—A writer in the *American Manufacturer* makes the following practical suggestions: Box piling very small scrap iron has long been practiced in the old country, and is a very economical way of working it up, and, if properly handled, makes a finished bar, without a seam, with once heating. Two sections of bars are required to form the box, or case; one for the top and bottom, and the other for the sides; and when filled, make a good pile, which requires no tying, and can be changed without much risk of falling down. The bars are rolled out of puddled iron at the forge rolls. Piles, up to several hundred pounds, can be made. When reading Mr. Wheeler's method of utilizing scrap steel, as described in last week's *Manufacturer*, I thought that this way would be suitable for his purpose and less expensive. There may be an objection to this form of pile, as it is open at the ends, and as the steel is reduced to a semi-fluid state, it might run out. This may be so in regard to steel; but it does not apply to iron scrap, which, in this way, can be worked up without reheating. Bars can be made in sections, so that old rails can be rolled into finished bars at one heat, where such quality is suitable. Baling scrap, in a scrapping furnace, is very wasteful, and increases the cost considerably, without improving the quality in proportion.

PACKING POLISHED SHEETS.—We read in an Eastern exchange that a manufacturing firm has introduced a new and improved method of packing their fine planished sheet iron, which must be very desirable for shipment to great distances, as well as when large lots require to be stored for any length of time. It consists of a large sheet of common iron turned up around the edges like a large bake-pan, which is done in a heavy iron press made for the purpose, in sizes to fit the sheets to be packed. Into this the required number of sheets are placed, and on this is fitted a substantial inch board covering; the package is then placed under a press which forces the whole down into the pan until the edges are brought up over the board, when it is strongly nailed to the wood, making a firm, neat and tight package that can be easily handled, and cannot fail to preserve the finished sheets in good condition for a long time, even under exposure that would ruin the iron in the old style of packing.

SCIENTIFIC PROGRESS.

Social Statistics.

A paper entitled "Births, Deaths and Marriages, and the Comparative Progress of Population in some of the Principal Countries of Europe," by Mr. Frederick Martin, author of the "Statesman's Year Book," was read recently before the English Statistical Society. Mr. Martin, says *Iron*, taking as the basis of his paper the vital statistics published in the last annual report of the Registrar General, gives the birth, death and marriage rates of nine countries, divided into three groups, the first comprising England, France and Prussia; the second, Austria, Italy and Spain; and the third, Denmark, the Netherlands and Sweden. For all these States except two, Italy and Spain, the calculation of averages per 1,000 of population, spreads over 22 years; while for Italy they comprise 12 and for Spain ten years. Mr. Martin showed in his tables, illustrated by diagrams, the striking differences that exist between the nine countries in the average rates of births, deaths and marriages. While in England and Wales the average annual birth-rate, per 1,000 of the population, was as high as 39.9 in the 22 years from 1853 to 1874, in France it was during the same period as low as 26.1, France standing, as regards births, far below any other country. The death-rate again varies enormously in the different States. While it was as low as 20.2 per 1,000 of the population in Denmark, it was as high as 32.2 in Austria; England filling a place only less favorable than Denmark and Sweden, the average rate having been 22.2 per 1,000 during the period. The marriage-rate, as may be expected, is subject to great fluctuations, springing from trade prosperity or stagnation, and good or bad harvests. The average annual marriage-rate during the 22 years was highest in Prussia, namely 17.3 per 1,000 of the population, and lowest in Sweden, 14.1 per 1,000. Among the tables given by Mr. Martin, perhaps the most suggestive was one giving the surplus of the average annual birth-rate over the death-rate, denoting the increase of population. It was 12.7 per 1,000 of the population in England and Wales; 11.6 in Sweden; 11.4 in Denmark; 10.7 in Prussia; 9.0 in the Netherlands; 7.7 in Austria; 7.5 in Spain; 6.9 in Italy; and 1.9 per 1,000 in France. It will be seen that England was the most progressive and France the least of all the nine countries, the population being almost stagnant. Mr. Martin thinks "France is the riddle of Europe."

INFLUENCE OF AGE ON LEAF AND FLOWER.—Decandolle, the celebrated Swiss botanist, has started a question which promises to be a very interesting one. Does a tree produce flowers or fruit earlier as its age increases, temperature and other circumstances remaining the same? He gives a number of observations to show that in some cases they do, and in other cases they do not, and botanists are in a quandary. It is generally found in these contradictory cases that there is a near reason, not discerned, that will explain the whole. It has been noted by American botanists (see Salem volume of "Proceedings of American Association") that trees of the strongest constitutions leaf the earliest. Thus there are varying times of leafing in Norway spruces, though both be of one age. In a severe winter, if one or two such die, it will be the one which leafs the latest. The early one is the hardest. Now a young tree is always more tender than one approaching a flowering condition. Young trees are often destroyed when older ones escape. This being the case, there would be a difference in the time of leafing between such young ones and their elders. On the other hand, where young trees had as strong a constitution as older ones, and there may be many such cases, there would be little difference.

A TRANSIT OF VENUS MEDAL.—The French Academy of Sciences have commemorated the observations of the transit of Venus by striking a medal. M. Alphee Dubois was intrusted with the execution of this object, and he has had recourse to the ancient mythology. On one side of the medal, Venus, "in the simple costume of goddesses," passes before the car of Apollo, the god of the sun. Science is represented on the earth—a female figure sitting and observing the phenomenon. The legend round the border is, "Quo distent spatio sidera juncta docent;" "the stars by their conjunction teach us by what space they are separated." On the reverse is "Institut de France Academie de Sciences. Passage de Venus sur le Soleil, 8-9 Decembre, 1874." The medal has been distributed to the members of the Academy, and to all the observers of the transit.

"POPULAR SCIENCE MONTHLY."—As a mark of the progress of popularized science in this country, nothing could be more positive than the fact that D. Appleton & Co., of New York city, find themselves forced to issue a monthly supplement to their excellent journal, the *Popular Science Monthly*. The limits of the regular magazine do not give space to the multitude of topics which are pressing for publication, and we know that eager readers will be glad to have the doubled amount of choice selected and original scientific literature which Prof. Youmans provides. We regard the new publication as a loud voice proclaiming American scientific progress.

OZOKERIT FOR PRESERVING METALS.—For preserving metal and other substances from decay and fouling, Mr. Charles Weightman Harrison, of South Kensington, proposes to dissolve the crystalline hydrocarbon known as ozokerit in any of its solvents, such as benzole, petroleum, oil of turpentine, or resin oil, and he then mixes the solution in any desired proportion with other suitable bodies, according to the purpose for which it is required. He mentions that his experiments have been made with ozokerit as a type of the mineral hydrocarbons, which are built up of molecules, containing not less than 20 atoms of carbon, such minerals being capable of resisting the action of all acids at ordinary temperatures, and suffering no deterioration from atmospheric influences. On this account he has found them valuable for mixing with gums, resins and colors applicable to a great variety of purposes for preserving, as they impart thereto a high degree of permanence. He explains that a simple and ready mode of preserving bright metals from rust is to rub them over occasionally with a wax formed by melting together equal parts, or nearly so, of ozokerit and beeswax. It is easily applied in a thin coat by rubbing the compound on the metal with a cloth. In applying this compound wax to iron he sometimes adds finely powdered plumbago to give it the color of the metal. Another compound or solution for preserving metals he forms by dissolving in a sand bath (say) four ounces ozokerit and four ounces marine glue in two pounds benzole, and then adds four pounds linseed oil and one-half pound essence of turpentine. The mixture is kept gently boiling in the bath for an hour or so, after which it is ready for use, and may be applied to the metal by a soft brush.

PRIZES FOR INDUSTRIAL RESEARCH.—The *English Mechanic* says: "Among various subjects in connection with which the Industrial society, of Rouen, has just offered prizes are the following: A substance capable of replacing albumen of eggs in all its applications to printing of tissues, and considerably cheaper; new sources of albumen, either in natural products containing it, or by transformation of other proteic matters; a new dark vapor as intense and solid as aniline-black, but not weakening the cloth, and capable of being printed with any other colors without alteration at the point of contact; a method for volumetric determination of commercial glycerine; a solid blue coloring matter, applicable like indigo, but cheaper; new process for fixing indigo blue by steaming; new method of fixing aniline colors; a new thickening matter to replace Senegal gum; production of ozone in the concentrated state; new application of ozone; industrial production of oxygen; rapid and exact means of determining the reducing power of a coal or any carbon; utilization, in metallurgical or ceramic arts, of iron pyrites, desulphurized by roasting; process of concentration or precipitation of nitrogen and phosphoric acid in fecal matters, urines and sewage waters, yielding a manure of at least 5% nitrogen, and 20% phosphoric acid."

NEW WEIGHING INSTRUMENT.—The ordinary chemical balance is, of course, rather a costly instrument, it being difficult to make the two halves sufficiently alike, and to combine stability with sensitiveness. M. Payer proposes the following arrangement for small weights. A two-armed tube is filled with mercury, and on one of the mercury surfaces is placed a well-fitting plate, which can move in the tube without friction. This serves as the balance scale, and the body to be weighed is placed on it. The liquid will rise in the other arm correspondingly, and equilibrium is at once obtained with great certainty. Place a known weight, one grain, for example, and note how high the mercury rises. Then place a second grain and note the additional rise. Going on in this way, a scale may easily be constructed. As for each rise in one arm there is an equal sinking in the other. This scale can be applied to the other leg also, of course in opposite direction. The sensitiveness of the arrangement is considerable. It can be increased by use of the Torricellian vacuum, the plate, with the body to be weighed resting, in this case, on the mercury in the open arm. The scale can here have no fixed zero, since the air pressure varies, which is only a slight inconvenience.

A NEW CHEMICAL ELEMENT.—Haddam, Conn., has furnished the material for the discovery of a new element, as announced by Hermann in the German *Journal of Chemistry*. It is found in tantalite, of which it forms a little over 6%, the rest being metallic acids of tantalum, niobium and ilmenium. Hermann calls it neptunium. He has so small a quantity of the material at his disposal that he has been unable to reduce the oxide to a metallic state. With soda it colors microcosmic salt golden yellow. It is the first element discovered for many years by mineral analysis, although in the past 17 years five metals—cesium, rubidium, thallium, indium and gallium—have been discovered by spectrum analysis. The atomic weight of niobium is 118.2, giving neptunium acid the formula Np_4O_7 .

ACTION OF SEA WATER ON LEAD.—The *Journal of the Chemical Society* says that, after keeping strips of new cut lead in a bottle of sea water, frequently shaken, for four days, no trace of lead could be detected in the water, but the bright surface of the strips was coated with an insoluble lead compound. Hence, lead pipes may be used in marine aquaria without any fear of injury to their inhabitants.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

MAHONEY.—Amador Ledger, May 14: This mine is now being operated by the company. S. D. R. Stewart is entitled to much credit for the enterprise he has displayed. Under his management the mine has been successfully operated, and in now surrendering the property in consequence of the expiration of his lease, he leaves it in first-class working condition. Mr. Benjamin is the new Superintendent, with Humphrey Rose as foreman. The working force, we believe, is to be kept fully up to the standard of the past year. There is plenty of pay ore in sight, and while this is in process of extraction, prospecting will not be neglected. The company have no mill of their own, though it is asserted on good authority that the quartz now in sight is sufficient to justify the erection of a mill; and perhaps the one dollar assessment just levied has something to do with securing such facilities.

Good Hope.—The water is being taken out of the shaft, preparatory to sinking. The work of draining is now about completed. Good Eastern men are furnishing the wherewith to develop the property, and are prepared to expend \$500 per month in prospecting. This will be quite an item for Jackson. We have never heard but one opinion expressed concerning this mine. All experts unite in pronouncing it a paying property, and the management is good management. The shaft is now down 150 feet, with a fair sized ledge of ribbon rock running from the surface to the bottom.

ZACATERA.—This mine is situated at West Point, Calaveras county. F. C. Hall, of Lone City, is now sole owner. This week the old boiler and smoke-stack used at the Onida mine was shipped to the Zacatera. A 10-stamp mill is being constructed and will be completed in a few days. The Zacatera has not been prospected sufficiently to determine its value. Plenty of good rock has been extracted, and there is plenty more in sight. The custom work around West Point is ample to justify the putting up of the mill. The quartz of this locality is much softer than any met with on the Amador vein. With 10 stamps it is calculated to crush about 40 tons per day.

BUTTE.

LOW WATER.—Oroville Mercury, May 19: Leander Delavan, J. C. Biorco and Daniel Paxton are mining in the Middle fork of Feather river, opposite to J. N. Turner's mill, at a place known to be very rich, but which has never been worked on account of the great amount of water in the river. This year it is low and in three weeks' time every drop of it will be running through a flume, and the bed of the river left dry to work. We shall not be surprised if they come out with a good lot of gold to the man. They are deserving of good luck, for they work hard and are honest men.

WILL BUILD.—A. J. Severance has begun the construction of one of the new mining machines, just above the bridge, to cost \$10,000, and to be completed by the middle of June. It will be recollected that Messrs. Hedge & Butterfield, the owners of the right, went some three weeks ago to San Francisco and formed a company, which was in due time incorporated. The capital stock was \$100,000, divided into 100,000 shares of \$100 each. Every dollar of the stock that they would sell was quickly taken. As they own a piece of the river above the bridge, Mr. Severance, now one of the company, will build the boat and the company wash the gravel.

MISNO MACHINE.—Again they are at work on the celebrated mining machine, the one with the lengthening cylinder. They moved the machine to a piece of ground owned by Col. J. C. Logan and W. S. Higgins, which was deeply covered with tailings. The cylinder was found to be long enough only to reach through the tailings and about a foot into the original bed of the river. The last two hours that it worked it took up \$60. With a cylinder long enough to work well, there will be no trouble in taking out \$500 per day. These gentlemen who own the ground are men not easily excited and have rare good judgment, and they claim that the machine will do all that is claimed for it. It is certain to get gold out of the river if there is any in it.

STILL BURNING.—Last week, just before going to press, we learned that Poppe's tunnel, at Cherokee, was on fire. We supposed that our information was correct. Since that time we have been informed by parties that it is only the rock that has been dumped at the mouth of the tunnel and the mouth itself that is on fire. It should be borne in mind that not a single piece of wood is in the tunnel or at its mouth. All the fire and smoke come from the rocks or some substance contained in them. Any way the mouth of the tunnel is so hot that it is impossible for one to get near it so as to see in or to work. The smoke arising from the dump is very thick, and the men's ranch. The fire is very strongly impregnated with the smell of sulphur. It certainly is something unusual, and for which no one has yet been able to account.

CALAVERAS.

GWIN MINES.—Calaveras Chronicle, May 19: We continue to hear the most favorable reports from the Gwin mine. The 1300-ft level has now been extended nearly or quite 100 feet since the pay shute was struck, and there is as yet nothing to indicate that the level is approaching the extremity of the body. Stopes are being rapidly opened, additional batteries set at work and the ore producing and crushing capacities of the mine are being urged to their full extent. The present condition and future prospects of the mine are excellent; in fact, more flattering to-day than at any other period of its history.

NEW MILL.—A new 10-stamp mill is being erected at the Wallace and Ferguson mine, at Sheep ranch. The lumber is nearly all on hand, and the work is to be pressed forward with vigor. The yield of Wallace & Ferguson, with only a five-stamp mill at work, has been marvelous. What will it be with 15 stamps?

QUARTZ MILL MOVED.—The 10-stamp quartz mill, owned by the Hughes Bros., situated in Chile gulch, about a mile this side of the Junction, was recently moved to the mine, belonging to them, in Old Woman's gulch. The mill was moved a distance of two miles—a large number of hands and a 16-horse team taking part in the transportation. Putting the battery in close proximity to the mine will very materially reduce the expense of milling the ore. The cost of hauling the rock will now be merely nominal, and we learn that water for milling purposes can be obtained at much lower figures than where the battery originally stood. The mill will be ready for operations in a few days. Good rock is being taken from the old Anderson Flat mine, which is under bond to an English company. A crushing of rock is being taken out, which, if it proves of a fair quality, will determine the sale of the mine. Rock from the Granite mine, owned by White & Co., is being crushed in the mill at the Josephine. A large quantity of ore—some 200 tons or more—is on the dumps. Extraordinary rich rock was lately discovered in the Lacey mine, about a mile this side of the Point. The ledge shows about a foot wide and the rock is said to be

incredibly rich. At the Champion mine active operations are progressing. A large force of hands is employed, running levels and stoping, and the mills will be set at work again in a few days. Splendid developments have lately been made in the mills owned by the Enterprise Consolidated mining company. A large body of rich ore has been uncovered, and all the indications warrant the belief that the mine will prove a permanent and paying one. At Railroad Flat, Clark's mine is running on custom rock. A new five-stamp battery is being erected on the Chapman mine at Railroad; expected to be in readiness for operations in a week or 10 days. Fair-grade ore is being taken from the Sunderland mine, at Independence, and there is an abundance of it.

INYO.

THE REX MOUNTS.—Inyo Independent, May 12: Among the notable local events of the next two or three weeks will be the starting up of the Rex Mounts (the old Silver Sprout) mill for the summer's work, it having been almost entirely rebuilt and supplied with the most improved reduction machinery for the use of the new company. Of the almost innumerable rich but small ledges which cut through Kearsarge mountain, the Rex Mounts veins present the greatest number in the smallest space, and have so far made the best returns for the amount of capital invested in working them. The mill, which is the result of incidental expenses of building trails and improving the old mill, the company realized handsome returns over and above the cost of prospecting, mining and milling. The Rex Mounts proper, consisting of four parallel ledges within a width of 150 feet are the most important so far as developed—in fact the first one of the four is the only one upon which any considerable work has been done. In all there are 15 ledges, including the four mentioned—the Potosi Nos. 1, 3, 5, 7, 8, 9, 11, the Boomerang and Arctic, which vary in width from 12 inches to four feet, all carrying the rich ore which has proved so productive by a working process. On the principal mine three openings have been made by tunnels running in on the ledge from the end, all showing distinctly the ledge and yielding good ore. Unless for drainage and ventilation, where run to tap the bottom of an existing shaft, we have but little faith in tunnel enterprises as a means of prospecting, but above all other mining districts in our knowledge Kearsarge hill presents the best inducements for an operation of this kind. A tunnel 6,000 feet in length would either cross-cut these 15 ledges or enter the highest at a point nearly 3,000 feet deep, where, from the pitch of the outer veins, all would enter. The matter of 75 feet of snow in the cañons near the present workings, as is the case now, wouldn't make much difference with mining operations then.

KERN.

TEHACHAPI COAL MINE.—Kern County Courier, May 17: Two miles from the railroad in Tehachapi, below what is called the Charley Moore canyon, in San Joaquin, at the left of the lake, a coal lead has been found which promises to be of greater value. It was located by J. B. Malin, Col. A. Lewis and Thomas Eveleveth, and is on a Government section. The owners are now working a ledge seven feet thick, and croppings can be found over the whole section. A mile square. It is likely to prove of more value than all the other mines in the county.

MONTEREY.

COAL AND MARBLE.—Castroville Argus, May 17: We were told while in Monterey, a few days ago, that work was going on actively at the Carmelo coal mine, 10 men being now employed, and that there was no longer any doubt of the property being a valuable one. It is said that the stockholders of the mine were made the victims of a "freeze-out" game, by which persons from abroad acquired control, but it is also stated that the former will, in due time, make a determined effort to wrest from the "sharps" the pretended ownership and management of the mine. The coal deposits, which are understood to be very extensive, are located some seven miles south of Monterey, and only a mile or two from the city of Carmelo. Further south there are quarries of fine marble, which are now being developed, and which, together with the coal discoveries, promise to bring additional capital and enterprise to old Monterey. These quarries lie near the coast, at a distance from Monterey of about 25 miles, and, as we learn, are in the hands of men of energy, who are laying them open with all practicable speed. The number of hands employed at the present time, though it is probable that a larger force will soon be put on, further discoveries (these of a bluish marble) having been made within the past fortnight.

NAPA.

OAT HILL.—Cor. Napa Register, May 19: The Oat Hill mine has closed down for the present. They are building a 16-ton furnace, which will be completed by the first of June, when work will again be resumed. Mr. McGee, the Superintendent, informs me that hereafter they will work white men altogether. No Chinamen "need apply."

THE GREAT EASTERN is still closed, and it is rather doubtful if they start up again for some time.

MR. GARRETT, of St. Helena, has a force of men at work on his copper mine, about five miles from this place, with a very good prospect. He has many tons of good paying ore on the dump.

JOHN LAWLEY has a large force of men at work on the Phenix mine, and is getting out a great deal of rich metal.

NEVADA.

BIG BLAST.—Nevada Transcript, May 18: The Milton mining company put off a big blast in the Manzanita claims, at Sweetland, on Sunday last. They used five tons of the new Judson powder, and those who saw it acknowledged it to be the most successful blast ever put off in that part of the county. It was placed in a drift 75 feet long and in the 75 150 feet each way, and it broke the ground full 80 feet beyond the powder line. The agent of the Giant and Judson powder, Mr. O. W. White, assisted in arranging the blast, and of course he was as much pleased with the effective work the powder did as were the owners of the claims. We understand a blast of about four tons will be put off in the North Bloomfield gravel mining company's claim and they will use the Judson powder, as it does its work most thoroughly.

GOING TO START UP.—Dennis Desmond & Co. have leased the mine near the New England, which is known by the name of the Mohegan. The company is composed of old miners of this city and Grass Valley. On account of the trouble with the water and the inability of the former owners to put up machinery, work was suspended on it a long time ago. The shaft is now down 45 feet and the last rock taken out yielded \$87 to the ton. The New England mine has drained the water from the Mohegan, and the lessees are going ahead determined to thoroughly prospect it, and if the water troubles them they will make arrangements immediately to put up machinery. They are practical miners, and we have no doubt they will soon be able to demonstrate that they have a good paying mine. In addition to the large number of mines that are now in operation. If the work goes on as vigorously in the next few months to come as it has during the past few months, we shall soon see Nevada City assume its pristine celebrity.

A BAR of gold worth \$2,600 was sent to San Francisco a few days ago, it being the result of a ten days' washing in the Main street bridge and extending below the Broadway bridge. It was thrown up by Chinamen to turn the water of Deer creek.

ABOUT A DOZEN Chinamen are working the tailings in Deer creek. In past years when worked by white men good pay was taken out, and we are of the opinion that the almon-eyed fellows are doing well.

NEW MILL.—We understand that Crosby & Mitchell, owners of the Main street bridge, at Grass Valley, propose putting up a 20-stamp quartz mill at their place,

for the purpose of crushing rock. As soon as they get the sulphurets works in active operation the new mill will be put up. It will be a great accommodation for quartz miners in that section, and be the means of encouraging prospectors, as the rock will be milled at a very low rate, and the sulphurets can be sold on the ground to the owners of the sulphurets works.

QUAKER HILL MINE.—Grass Valley Union, May 19: The Quaker Hill mine, owned by George F. Jacobs and A. A. Sargent, is taking out gold to the satisfaction of all concerned. Ordinarily at this season of the year, the owners have had plenty of water of their own to wash with, but this year have to purchase what they use. Even with the expense of water the mine is paying handsome profits. A portion of the claims will have to be worked by drifting, but that plan need not necessarily be adopted for several years to come.

PLACER.

WATER SEASON.—Dutch Flat Forum, May 17: The weather continues cool and we have been favored with considerable rain for this time of year, all of which aids in prolonging the water season. There is no change worthy of note in the various claims that are running. They are all under full headway, and the Superintendents appear determined to wash as continuous as possible while the water lasts.

THE BAKER is preparing for a blast of 300 kegs of powder, which will be ready in a few days. The blast in the Baker claim proved to be another success, and loosened a large amount of gravel on the west side of the pit. This claim is now using water nine hours per day. The Summer-set cleaned up on Saturday last, producing the largest result realized from that claim in a long time. At Gold Run, the North Star, Bonanza, Illinois and the claims of the Gold Run Hydraulic M. Co. (limited), continue washing with vigor.

LITTLE YORK MINES.—Work in the Empire mine has been interrupted considerably of late, caused by the sliding of a loose strata on top. The Christmas Hill company turned off last week and cleaned up, and the further working of the mine is laid over until such time as a change is made in its general workings, as the present tunnels, etc., are of no further use, and new ones will have to be constructed.

LOST CAMP MINES.—Hydraulic in the Harkness mine has been in steady progress since the first of January, during which time but one general clean-up has been made. This claim embraces 400 acres of mining ground, with an average depth of 100 feet, 1,000 inches of water is used, which is supplied by a ditch belonging to the mine, drawing its supply from Blue Canyon ravine, and is capable of furnishing a stream of 1,000 inches five months in the year. The Boston claim is worked under the supervision of John Rathburn and Wm. Bellows, and is an extensive drifting mine, which is successfully worked during the entire year, and has continued to pay well since opened.

LOWELL HILL MINES.—Work in the Swamp Angel mine is being prosecuted with vigor. The main tunnel continues to be opened, and new drifts are being run up, all of which looks well and yields well as worked. The various prospecting tunnels in this vicinity are being advanced as fast as circumstances will permit, and a number of which will soon tap the auriferous gravel, which, when accomplished, no doubt this divide will be able to boast of several more dividend paying mines.

LIBERTY HILL MINE.—Washing continues in the Liberty Hill mine. The work of removing the lower strata is making slow but steady progress, and is thought will pay well.

YOU BET MINES.—A blast of 550 kegs of powder was exploded in the Neece & West mine on the 13th inst., which did splendid execution, enough of the gravel being pulverized to make a large run. Water was turned on the same evening. Owing to the scarcity of water the washing, and the conclusion of several successful runs, has shut down for the season. Washing in the Hussey continues with unabated success. The Nevada M. Co. are now washing from four points, all of which are doing well. The yield of gold from this mine, it is said, will be very large this year. The large tunnel under construction from Wilcox ravine, which will tap the bottom of the channel in this mine at a distance of \$9,000 feet, is now advanced 850 feet.

REMINGTON HILL MINES.—The Rhode Island Co. still have sufficient water to continue ground sluicing and are doing well. The advancement of both tunnels in the Wide West mine is progressing rapidly and paying well. The side drift opened east of tunnel No. 2, is extended 50 feet. At this point the channel is several feet deeper than where it is tapped by the tunnel, and is also said to be considerably richer. Breasting out has also been commenced, the returns of which are sure to be large.

GREEN VALLEY MINES.—The Opel Co. has suspended further hydraulic, as it was found that the upper strata besides being very hard, did not carry sufficient gold to pay for its working. The lower strata is known to be rich, and will yield large returns for drifting, which work is now under progress. The Hayden Hill Co. continues to work hydraulic at intervals, and supply of water not being sufficient for continuous washing, but they expect to accomplish enough work during the season so enable them to disturb a good dividend. The Novey Co. has tapped the cement in the lowest part of the channel. The mill is now in operation crushing. There are deposits of loose gravel mixed with the cement which is being washed without crushing. The mine is looking splendid.

GOOD ROCK.—Fleecer Herald, May 19: Sheriff and Landlord recently struck and mined a new ledge near Crosby's ranch, about a mile and a half north of Auburn. The rock taken out in sinking up to a recent date amounted to about three tons, which they have had crushed at the Evening Star mill, and realized from it \$410.10, or a little over \$130 per ton. This they say is average rock, and for an average it certainly is not bad.

PLUMAS.

BLUE GRAVEL.—Plumas National, May 19: This company, whose claim is just across the Middle fork from Pauley's hotel, are still running their tunnel from the shaft, in bedrock, and are now about 100 feet from the shaft. They will run a tunnel and connect it with the gravel this week. The new machinery works smoothly, and does all that was expected of it. The prospects for this company are bright in the extreme, and the boys deserve them, for they are all hard working men, who have a right to a fortune, whether they get it or not.

RICH CLAIM.—The somewhat noted mining claim on Footman's creek, purchased by a San Francisco company, last summer, from Healy & Lanthier, is turning out splendidly. The run of water is necessarily light this dry season, as the ground is situated well up on the creek, but we are informed that the company have made big pay, and that with the usual run of water they could easily have cleaned up \$25,000 for the season's labor. There are plenty of just such claims in Plumas, and they will come to light as fast as capital and well directed labor commence the search for them.

ANOTHER RICH LEDGE.—A strike has recently been made at Last Chance, a place about six miles below Onion valley, near the Middle fork of Feather river, by Mr. McMartin, which bids fair to be a rich thing in quartz. The ledge, we are told, is six or eight feet thick, crops out for a long distance and prospects well and uniformly. If it were in the Greenville section, it would be the subject of much comment. The ledge is now being worked, and a place like Last Chance, it will be some time before its merits will be thoroughly discussed. The owners, McMartin & Mullen, are making arrangements to prospect it thoroughly.

FRANKLIN.—On Monday we stopped a few minutes at the Franklin shaft, on Willow creek, and found everything in a fine state. The shaft is now down something over 100 feet, and the lava is changing considerably in character, being mixed with washed gravel, iron-ore, quartz, etc. Considerable water is coming in, the calculation being that the pump is raising 82 gallons per minute. It is not increasing, however, and can be handled without trouble so far. They expect to break through into gravel in the next 20 feet, and to get bedrock in the next 40 feet.

SURVEY MADE.—Surveyor Keddie has lately been down

at French ravine, making a survey of the ground of the ground of the Rich Bar quartz company. The owners of this celebrated mine are making arrangements to get a patent.

GIBSONVILLE.—On Sunday last we paid a flying visit to this old-time mining camp, and found it looking lively, mining and smelting, having returned in full measure. Several of the gravel claims in that vicinity are paying well, and many workmen are employed, who, with the usual recklessness of Californians, apparently only use the hard-earned wages to "make it lively." On the whole, Gibsonville looked lively and prosperous, and the opinion of mining men in that vicinity, who are well posted in the state of the mine in the vicinity of that town, is almost inexhaustible. The United States Book companies are now hiring a large number of men, and the ground is paying well in each claim. The North American, at Newark, is also doing well. Several large gravel claims will soon be opened, and we can see no reason why this section should not continue to prosper for years to come.

SAN BENITO.

COAST MINES.—San Benito Enterprise, May 19: From Andrew Paulson, who has been working in the Salinas mine for the past year, we learn that its managers are driving a tunnel for the purpose of tapping the main shaft. They expect to be able to do it in 600 feet. The tunnel is now 400 feet. Similar to the one now being run on the Comstock, Con. Wonder and other mines in that range. The Salinas mine is being worked for quicksilver, of which there is a splendid prospect; while the other claims are mostly operated for antimony. Some very high grade cinnabar has recently been struck in the Wonder tunnel, also in the Comstock. The Ham-burg mine has been attached by the employees for wages, and temporarily shut down in consequence. The Stanton mines still continue to produce large quantities of fine antimony, but the furnaces, for some cause unknown to our informant, still remain idle.

SIERRA.

SOUTH FORK.—Mountain Messenger, May 18: Preparations are being made to renew work in this claim at Forest City.

THE EMPIRE mining company of Sierra county have declared a dividend of \$1 per share, amounting to \$10,000.

VERY RICH.—Out of a candle box of quartz from the North Fork claim, Forest City, the handsome amount of \$42 was taken.

BRANDY CRY.—Hickey and Arnett are still running. Bunker Hill company commenced work last week, and are running their tunnel in to sink down on the channel for which they are searching.

Nevada.

WASHOE DISTRICT.

JUSTICE.—Gold Hill News, May 23: Daily yield, 400 tons of ore, keeping the mills steadily crushing. The ore breasts and stopes are yielding well from the 400 down to the 800-ft level. The bullion returns show an increase in the value of ore milled, and the appearances are that the yield will be continuous and uninterrupted for months to come. The winze below the 800-ft level is being continued steadily downward, the bottom still in good ore. The entire size of the south drift on the 800-ft level is in a solid body of fine ore, requiring continuous blasting. This ore is of splendid character, and to all appearances is liable to form an extensive and very valuable body. This drift shows that the ore extends much further to the northward on the 1000-ft level than it has on any of the levels above, and indicates that the extent of pay ore in that portion of the mine will far exceed both in quality and amount the production of any level yet opened.

YELLOW JACKET.—The station for the 3200-ft level eastward from the bottom of the north winze being opened, the main drift east, cross-cutting the vein, as well as a lateral drift south, are both commenced and each is in about 25 feet to-day. The new shaft is down 700 feet. Material at bottom hard, andesite, with considerable water to contend with.

CAIRO.—Daily yield, 500 tons of ore. The ore stopes on the 1600, 1550 and 1500-ft levels are all looking well and yielding the usual quantities of rich ore. Winzes are being sunk below the 1600-ft level to connect with the lateral drift on the 1650-ft level for ventilation purposes. The north drift in the ore vein on the 1650-ft level is making slow progress on account of the intense heat. A breakage of the crank-shaft of the driving engine of the Con. Virginia mill has somewhat interfered with the regular bullion returns from that quarter, but the decrease in the production by that mill is being much more than made up by the Sacramento and Occidental mills, both of which have been started up and are now crushing California ore.

CON. VIRGINIA.—Daily yield, 400 tons of ore, keeping the mills running to their full capacity. The ore stopes on the 1650-ft level are yielding rich ore, but are intensely hot. The south ore stopes on the 1550-ft level are also yielding splendid ore. The ore stopes on the 1400-ft level are looking well. The 1750-ft station of the C. & C. shaft is finished, and a drift has been started to cut the ledge, which is now in a distance of 50 feet, the face in hard blasting ground.

GOULD & CURRY.—Putting in the new pump bob at the head of the main incline is being pushed, with all possible vigor. The south drift on the 1700-ft level was connected during the first part of the week with the Savage combination winze, giving a splendid circulation of good air, and greatly cooling the entire southern portion of the mine.

CALEDONIA.—Sinking the shaft is making the usual excellent progress, the bottom still in quartz of a fine character. The body of quartz has a very appearance of being large, is heavily impregnated with pyrites of iron and assays from \$5 to \$20 per ton.

CROWN POINT.—The main east drift on the 2000-ft level continues in porphyry mixed with quartz, which assays from \$5 to \$6 per ton. The flow of water is still strong and the drift intensely hot, so that the progress is necessarily very slow.

THE UPRIDE from the 1465-ft level continues in a fine character of quartz, carrying some spots of fine ore.

NORTH CON VIRGINIA.—For several days past operations in the mine have been suspended in order to make some necessary changes and improvements to the machinery.

OVERMAN.—The east drift on the 1400-ft level is being pushed ahead, the face still in quartz and ledge marker. A drift north from the east drift has been started to connect with the south drift from the Belcher on the 1000-ft level. The west cross-cut on the 1100-ft level is still in fine quartz and has not yet reached the west wall of the ledge.

BULLION.—A drift has been started north from the east drift on the 1600-ft level to determine the character of the vein in that direction. The body of quartz on the 2000-ft level has crossed the Eschequer line, and preparations are now being made to run an east cross-cut in the Eschequer ground to determine the value of the ore vein.

SILVER HILL.—The north drift on the 650-ft level yesterday cut through the casing of the ledge and encountered a strong flow of water, which forced a temporary suspension of the work until the head of the water is drawn out.

ATLANTIC CON.—The main tunnel has been temporarily suspended for the purpose of sinking a winze on the ore vein below the tunnel level.

BEST & BELCHER.—Cross-cut No. 1, on the 1700-ft level is being pushed steadily forward, the face in porphyry, carrying spots and streaks of very favorable quartz. Cross-cut No. 2, now under construction, is being pushed on Saturday last, with strong indications of water in the face, so that it was deemed best to stop the drift until the pumps of the Gould & Curry were ready to receive it.

JULIA.—The face of the main south drift on the 1800-ft level continues in quartz and ore of a fine character. This drift is being pushed with energy, the body of quartz through which it is running having every appearance of being an immense deposit.

THE ENGINEER.

Transmission of Power by Wire Ropes.

The first attempt to transmit power at a distance by means of metallic belts or ropes, was made by the brothers Hirn in 1850, at a calico weaving establishment, near Colmar, Switzerland. An immense mass of scattered buildings seemed to forbid the possibility of using them, and yet placing the motive power at any one point. In this emergency, they first tried the method of force transmission, using a riveted steel ribbon to each building from the engine-house. The steel bands were about two and a half inches wide by one-fifth of an inch thick, and ran on wood-faced drums. This presented two inconveniences; in the first place, on account of its considerable surface, the band was liable to be agitated by the wind; and secondly, it soon became worn and injured at the points where it was riveted. It served, however, very well for 18 months to transmit 12-horse power to a distance of 80 meters. The success of the principle was complete, but much remained to be done before the wire rope and the rubber or leather-lined driving-wheel solved all difficulty and brought the principle to a practical reality.

The number of applications of this method of transmitting power increased very rapidly. At the end of 1859, there were but few applications in use. In 1862, there are known to have been 400, and in 1867 about 800. At the present time there are several thousand in successful operation. In 1864, a terrible explosion almost entirely destroyed the great powder-mill at Otkhta, situated about six miles from St. Petersburg, Russia. The whole establishment was rebuilt. After studying many combinations, an artillery officer proposed to profit by the resources which the telodynamic cables offered to engineers, and thus to realize the only combination which could prove successful in a powder-mill, namely, a great distance between the buildings, so that the explosion of one should not entail the ruin of the rest. The new establishment which went into operation in 1876, consists of 34 different workshops or laboratories, to which motive power is transmitted by means of wire ropes driven by three turbines, thus distributing a total of 274-horse power along a line nearly a mile in length.

The largest transmission is that employed to utilize the falls of the Rhine, near Schaffhausen, in Switzerland. Advantage was taken of the rapids at one side to put in a number of turbines, aggregating in all 600-horse power. As the steep rocky banks forbade the erection of any factories in the immediate vicinity, the entire power was transferred diagonally across the stream to the town, about a mile further down, and there distributed, certain rocks in the water being made use of to set up the required intermediate stations. In the industries, we frequently meet with a similar case. Many valuable sites for water power are lying idle in this country for want of building room in their immediate vicinity. New England especially abounds with them. Coal being so dear there, their value is all the greater. Since the water can only be let down hills in certain directions, the cost of a canal or flume would in most cases come too high, and so the power remains unimproved. By wire-ropes, however, we can convey the power of a turbine or water-wheel in any direction, both up and down stream; up an ascent to the top of a bank or down a slope. The power need not be confined to one factory, but may be distributed among a dozen, if necessary, located so as to suit their particular business, and not to suit the often-times inconvenient location of a canal. Thus, by means of the transmission of power by wire-ropes, we may utilize all this power that is now being wasted, and devote it to a useful purpose.

The history of the application of the wire-rope to the transmission of power (the facts of which, as given above, we take from the *Builder*) would be incomplete without acknowledgement of the valuable inventions of A. S. Halladie, of S. F. His work is well known on this coast, and readers of the *PRESS* will count him for a high place in the progress of wire cable utilization.

Cement and Broken Stone for Culverts.

A writer in the *Railway Age* aims to meet the needs of builders, by describing culverts of grout made with cement mortar and broken stone for culverts, in a country where stone of good quality is scarce.

For a two to six feet culvert, make a good stone foundation, laid in a trench dug for the purpose, and cover it with grout made of cement mortar mixed with coarse gravel or broken stone, in or on which lay a penstock of desirable diameter, the staves made of any cheap lumber, one inch in thickness and four or five inches wide, properly hooped, laid on the grout, and cover it with grout from three to six inches, according to the diameter of the culvert, covering the grout with dirt as the work progresses, so it will not dry, but harden. Two or three months' durability of the penstock would be all required of it.

In cases where larger culverts are required and stone can be procured for side walls, and money can not for cutting the stone to make a stone arch, lay up the side walls to the height required, the whole length of the culvert to be made. Then make a strong wooden arch, well braced, from five to ten feet long, with its span

or base line a little shorter, say one or two inches, than the distance (or width) between the side walls of the culvert, which we might call the abutments of the arch. Then commence at one end of the culvert and set the wooden arch so one end will rest firmly on the inner side of the top of one of the abutments, and the other on a piece of plank lying on and projecting over the inside of the other abutment on a line of about two inches of the inner face of the abutment. It would require about three pieces of plank at equal distances and made to support that side of the arch by putting heavy stone on the part of the plank lying on the abutment. Or, that side of the arch might be made six to twelve inches longer than the other, and rest on strong pieces of wood built in the wall the same number of inches from its top. Or, the base line of the arch might be made about four inches less than the distance between the abutments, and both feet of the arch rest on two or three boards laid across the abutments at equal distances. After the arch is adjusted in place, lay stone along the base of each side to prevent the grout from falling inside, and then put on the grout over the entire arch to the desired thickness, covering it with dirt as it progresses, to favor the setting of the cement, and as soon as it is sufficiently hard, saw or cut out the wooden supports and take out the wooden arch from the inside, move it below and set it up close to the section of grout arch built, and complete another section, repeating the operation until the whole culvert is completed.

I have in my mind a culvert with side walls laid as in an ordinary box culvert, about five feet apart and six feet high above the pavement.

Longest Tunnel in the Union.

The *Baltimore Gazette* says: "Few people know how great an engineering enterprise is going on in Baltimore county. For one thing alone, a tunnel six and four-fifths miles long, 36,510 feet, is being built under ground, for over four-fifths the distance through hard gneiss and granite. It will be the longest tunnel in the country, and there will be only two larger in the world—the Mont Cenis, which is eight miles in length, and the St. Gothard, now in progress of construction, and which is to be nine and a quarter miles. The fact that the water supply tunnel lies near enough to the surface to allow of numerous shafts, greatly facilitates its construction. The tunnel is a circle 12 feet in diameter, and extends from the Gunpowder river, about eight miles from the city, to Lake Montebello—the distributing reservoir—near the Hartford turnpike, about a mile and a half from this city, the direction being 26° west of south. This tunnel will conduct the water from the Gunpowder river to Lake Montebello. Thence a conduit, 4,120 feet long, known as the Clifton tunnel (from the fact that it passes under a portion of the Clifton park), conducts the water to a point just south of the Hartford road, where it enters six mains, each four feet in diameter, which convey the water to the city, a distance of 1,900 feet. The country along the line of the works is hilly, and the tunnel varies in depth below the surface from 67 to 353 feet. There are 15 shafts in the main tunnel, the deepest extending 294 feet below the surface. The water rains down from the crevices of the rocks, and pours along the bottom of the drift. Gangs of men, each with his miners' lamp attached to his hat, are hard at work picking and delving in the flinty bowels of the earth; and the monotonous clang of the hammer upon the drill is constantly heard, except when everything is in readiness for firing a mine, when all retire to a safe distance, and thunderous reports roll through the rocky corridors. The work of the tunneling is all done by hand, it being cheaper than the machine work in a drift of such narrow diameter."

MEIGGS' NEW ENTERPRISES.—We read in the *Railway Age* as follows: Henry Meiggs, the Peruvian railroad contractor, who has been probably the largest foreign purchaser of American railroad material and the largest employer of American engineers also, has this month resumed work on some of the unfinished lines on which work has been suspended for some time for lack of money, under a contract which gives him control of the great Cerro de Pasco mines, which, since the Spanish conquest, are said to have yielded \$500,000,000 in silver, but have been substantially abandoned for some time because of the cost of working at the depth attained, where it was almost impossible to bring heavy machinery, and drainage is indispensable. Mr. Meiggs not only intends to make the mines more accessible by a railroad, but to excavate a drainage tunnel, and it is claimed that this is likely to expose to easy working as much ore as has already been taken out from the mine. The government is to receive from 30% to 50% of the yearly net product of the mine, according to the amount taken out. Mr. Meiggs is to obtain the capital for the new works, the government guaranteeing interest and appropriating guano to secure it. Capital is not likely to be easily obtained on these terms, and Mr. Meiggs begins by issuing \$1,250,000 of his own circulating notes to provide for the opening of the work. In the company formed by Mr. Meiggs there are besides himself, Messrs. John L. Thorndike, Charles S. Rand, James H. Sherman, Minor K. Meiggs and W. H. Cilley, some of whom are well known to American engineers. Some of Mr. Meiggs' former employes have been recalled from America for this new work, but it is not likely to require, at present at least, anything like his former force of engineers.

One of the Famous Bridges of the World

The Cincinnati Southern railway will be famous in the engineering world for its bridges, two of them ranking in certain respects, above all others yet constructed. That over the Kentucky river just completed and successfully tested, is the highest as well as one of the longest, in the world, rising to the lofty elevation of 275 feet, with a total length of 1,125 feet. The center span measures 375 feet, the two other spans 300 feet each, and the attachments adding 150 feet more. The next highest bridges in existence are one in Switzerland, 254 feet high, with a span of only 154 feet, and one in the Andes in South America, 252 feet high, with spans of 125 feet. The bridge to be erected for the same railway over the Ohio river will claim pre-eminence for length of span. The channel span will measure 520 feet, and will thus be the longest truss span in the world, exceeding by five feet, the great bridge of the State railway across the river Leck, in Holland, and, by the same length, the three spans of 515 feet each across the Mississippi at St. Louis. Engineering skill is constantly growing more daring, and it may almost be said that there is no abyss so deep or so wide that our bridge-builders cannot throw across it a firm highway for the locomotive.

DRAINING OF THE ZUYDER ZEE.—Active preparations are going on for the immediate commencement of the long-projected work of draining the Zuyder Zee. A dam 40 kilometers (24 miles 1,504 yards) long, and 50 meters broad at its base, is to be carried across the gulf, built up to a height of half a meter above the ordinary level of high tide. Upon this pumping machines of 10,000-horse power will be erected, capable of pumping up from the enclosed sea, and discharging on the outside of the dam, 6,500,000 cubic meters of water daily. Taking the average depth of the water at four and a half meters, it is estimated that the work of pumping will be completed in about 16 years from its commencement. The total cost of reclamation is set down at 335,000,000 francs; but, huge as this sum is, the undertaking is confidently looked upon as likely to prove a most remunerative speculation. The success of the scheme will add to the kingdom a new province 195,300 hectares—nearly 500,000 acres—in extent. Judging from previous experiences in connection with Haarlem sea, it is reckoned that at least 176,000 hectares of the land thus won will be applicable to agricultural purposes, which, at an average value of 4,000 francs only per hectare, will richly repay the enterprise and treasure lavished on the gigantic undertaking.

Some of the Mines at Ward.

The *Ward Reflector*, in an article describing the mines, says: The first mine met with as you penetrate the upper air from Ward is the Paymaster, the first mine discovered in the district. A short distance above the tunnel a small bunch of croppings still protrude, near which Tom Ward sunk a shaft to the depth of 38 feet in '72, missing a body of rich ore by a few feet. These solitary croppings account for our presence here to-day, for in the event they had not existed, all of us would have been elsewhere. The prospector, as is well known, is not averse to crossing desert wastes—they have no terrors to him—in search of argentiferous or auriferous deposits; but when it comes to delving, running cuts or trenches he weakens, that sort of thing would be degrading, would detract from his capacity to judge from surface indications, etc. The peculiar traits of the inveterate prospector being taken into account, we naturally conclude that Ward would not be known even now were it not that these croppings still rear their heads above the deposits of earth that sun and frost and cloud-burst had lodged against them for centuries.

We had designs on the Ready Cash, and followed a trail leading to it, and in due time put in an appearance, but found to our disappointment that work was suspended on the seventh day at this particular mine, and as there was no one to interview, attention was directed to a body of carbonate ore extracted from a strike mentioned about a week since, which looked refreshing. Disappointed at not meeting any one at this mine, our course was at once shaped for the

Defiance,

A "way-up" mine, at least it occurred to us that it was pretty high up, before the home station was reached. On arriving, the services of Ed. Kenney, foreman, was secured to lead the way, and this carbonate-producing mine was "taken in" to the best of our ability. The very latest development in the Defiance, and which may be heard from in a substantial way, is a body of gray carbonate struck on the 5th inst., which gives promise of opening up better than anything struck in the mine up to this time. If it holds its own a drift will be run from the south winze in order to tap it about 110 feet below where the body is worked at present. Gray carbonate, as is well known, is the best quality of smelting ore found in Nevada or Utah. The Defiance, we understand, is to be worked eventually through a shaft.

The objective point, after leaving the Defi-

ance, seeing that nothing was doing elsewhere, it being Sunday, as before stated, was the

Paymaster.

We have visited this mine several times before, but not until Sunday last was the opportunity offered for a thorough investigation. The mine is worked through two tunnels—an upper and lower—the distance between them on the perpendicular being 100 feet. The lower tunnel is now in about 1,100 feet. At about 900 feet from its mouth the

White Chamber

Has been opened up on the west side, its dimensions being about 60 by 25 feet, the timbering of which has been about completed by B. T. Snell, who has charge of that department, and by whom we were piloted through the workings until relieved by W. G. Lyons, the foreman of the mine. The ore of this chamber is said to assay \$450 throughout. It leaves the contact to the east and is entirely in porphyry. The practical miner calls it granite, but the geologist pronounces it porphyry. At any rate it is a difference without a distinction. It matters little what the formation is so the ore is there, and we believe it is. If the formation was granite the inevitable mica would be there, but it is not; consequently we conclude it is not granite. That this defined body of ore goes down is a reasonable supposition, for it is not possible for it to shut square off with the level of the tunnel. Future explorations will determine this, so it is useless to raise the question at this time. Next in importance to the White Chamber at this time is the

Lyons' Winze,

Where a large body of rich ore has been encountered and is now being sent down through a chute to the lower tunnel. The greater portion of this ore is quite as good as that coming from the White Chamber, and then again, some of it will double discount it. Large quantities of ore going as high as \$5,000 have been taken from this winze, and a body of it is still exposed. Mr. Lyons we consider the right man in the right place, and if the opportunity presents itself, will not be found wanting. He has an eye on several bodies of ore that have been exposed along the line of these tunnels, which until now have remained undisturbed. It takes some little time for a man to become thoroughly acquainted with the ramifications of the Paymaster, and to comprehend it thoroughly it is necessary to apply one's self assiduously. The

Clay Chamber

Of this mine, which is being worked through a shaft, now down about 70 feet, is, according to our way of thinking, a bonanza in itself—a bonanza as is a bonanza. The shaft, as above stated, is 70 feet deep, and with the exception of about 15 feet of surface ground, is all the way in ore. How wide, long, broad, or anything about its extent is not known by any one at present. A number of assays have been made from this body of ore, some going as high as \$1,500, and none as yet lower than \$700. It has not been deemed necessary to have assays made from the waste, for the dividing lines are too plainly marked. Give us our choice and we will take the Clay Chamber all the time, even though other portions of the mine produce richer ore, its extent compensating for what it may lack in richness.

Electric Exploders.

In view of the recent disastrous discharges of exploders at the Sutro tunnel, some interesting experiments have been instituted by Mr. Sutro with a view of ascertaining the cause, and more especially to determine whether the electricity of the body might not have, in this high altitude, something to do with it. In speaking of these experiments, the *Independent* says:

Electric exploders made by different parties were taken, one after another, and placed in a strong wooden box, which again was placed in another box in Mr. Sutro's parlor. This room is covered with a heavy Brussels carpet, walking over which causes the human body to be speedily charged with electricity. Mr. Hancock, the chief blaster, assisted in the experiments and held the wires, while Mr. Sutro walked around the room two or three times, with slippers, sliding his feet gently over the carpet. After doing this he approached the end of one of the wires with his fore-finger, and instantly a loud report was heard, the exploder having been discharged.

The experiments clearly established the fact that exploders may be set off by electricity accumulated in the human body, and the men about the tunnel were at once informed of the fact. Instructions were also issued for handling them hereafter, and a sheet-iron plate was placed on the floor of the exploder house, to which is connected a wire reaching into the water flowing from the tunnel. The men in handling the exploders now stand on this iron plate, and have instructions to wet their boots before entering, and to put on India-rubber gloves before touching the exploders. If these precautions are properly carried out there need be no danger of explosions hereafter. Any electricity accumulated in the human body will be carried off through the iron plate, while the rubber gloves, being non-conductors, form an additional protection. No accidents from these explosions have ever occurred in the tunnel, for since the place is very wet no electricity can be retained in the body.

Adulteration of Foods.

Editor's Notice.—Having just read an article on the adulteration of food in the *Toronto Globe* of April 27th, 1877, it reminds me that we, too, might as well begin to rebel against eating trash. I never use spices, mustard or anything from the grocers in cans and bottles under those fine-looking labels, but that I feel reproached for wasting hard earned money and imposing on the stomach of those that partake of the food. If I could procure a small hand-mill that I could grind things fine enough with, I never would buy another box, bottle or can of anything again. I think if the newspapers would take the trouble to investigate and expose the adulterated brands of condiments it would make manufacturers more honest. It comes very hard on the class of working people to pay such high prices for necessary articles and find them unfit for use. I had to throw away a two and a half pound can of pepper, as it was so mixed with decomposed wood or browned sawdust, or something that made it smell unfit for use, and I have many times put a whole bottle of cinnamon in a baking of pumpkin pie, and they would not taste stronger than if one teaspoonful of the pure article had been used; and the bottle cost 25 cents, while one teaspoonful of the pure article ought not to cost above five cents. The last sack of fine table salt I bought was so adulterated that I could not safely use it. I was afraid it contained lime. The sufferings of dyspeptics are greatly enhanced, and many cases probably caused by this dishonest practice, and who knows how much life is destroyed by it in time.—Mrs. G. E. CHILDS, Santa Barbara, Cal.

The subject which our correspondent broaches is of the highest importance. It is an evil which has been felt in all states and countries. The remedy is by means of laws punishing adulteration and the appointment of State analysts and microscopists to furnish evidence against adulterators. Our correspondent is doubtless aware that charges of adulteration must be accompanied by actual proof that foreign substances are introduced. To show this there must be official analysis, and then the press can put forth statements which will enable people to shun the dangerous and the counterfeit. Until these necessary facts are set forth, the newspaper can do little more than throw out general warnings. These may do good in many cases, but they cannot have the definiteness which the descriptions of the evil should possess. Few editors have the ability, and none, whom we know, have the time to pursue studies of manufactured foods with the thoroughness which should characterize them. The matter should be handled by State examiners, and adulteration should be punished by rigorous laws.

So far as we know, the English have done more than any other government to protect its citizens against the crimes of the adulterator. There are government examiners in all towns, and they are zealous in testing everything which is presented to them or which they have reason to suspect. The result is that adulteration of foods in England has declined to a wonderful extent. So careful and wide-reaching have been the achievements of these examiners, that numbers of books have been printed showing forms and substances used in adulteration, and the ways of detecting them, and the whole people have been awakened on the subject. With the description of the evil there is also given, in all cases where it is possible, simple tests to determine the purity of materials which are of great practical use to the people.

In the United States there is springing up renewed interest in this important question. We are not aware how many States have special laws and official examiners, but Massachusetts has the system in good working and great beneficial result to the people. New York, during the last winter, passed a new law against food adulteration. During the last few months in New York City sellers of impure and watered milk and vendors of other fraudulent articles have been brought to grief for their evil practices. In our own State there are laws against adulteration, but though the laws may be good, we are not aware that they are supplemented by the necessary agencies for detection and presentation of evidence for prosecution. The following is Sec. 382 of the Penal Code, which makes adulteration a crime:

"Every person who adulterates or dilutes any article of food, drink, drug, medicine, spirituous or malt liquors, or wine, or any article useful in compounding them, with a fraudulent intent to offer the same or cause or permit it to be offered for sale as unadulterated or undiluted, and every person who fraudulently sells, or keeps or offers for sale the same, as unadulterated or undiluted, is guilty of a misdemeanor."

The purity of articles sold as food is of vital importance. We appreciate this fully and are ready to do everything in our power to convince the people that they should be protected against evil workers. Perhaps in this way the attention of the law-makers may be gained and the State will assume the responsibility for the detection of fraud, which is its province. We cheerfully offer to make microscopic examination of any material which our readers suspect of being adulterated, and we may thus expose the methods and materials used by the adulterators. The microscope is excellent evidence on many points of adulteration, as has been shown in the English literature on the subject.

The case of poor salt which our correspondent mentions was probably the result of natural impurities. Nearly all, if not all natural salt (*Sodium chloride*) contains chloride of lime in varying quantities, and if this is not removed the salt is not fit for table use or curing purposes. Although it is probable that nothing was added to the sample which our correspondent found unfit for use, it was fraudulent to put forth as "pure table salt" an article containing offensive natural impurities.—*Rural Press*.

USEFUL INFORMATION.

Facts about Metals.

Four hundred years ago but seven metals had been discovered, and we are now acquainted with the existence of 51, 30 of them, nearly three-fifths, having been made known to us since the beginning of the present century. It is not perfectly clear of two or three of these that they are really elementary substances, but it must be remembered that these doubts only apply to metals of such extreme rarity that chemists have not had a fair opportunity to examine their properties, and, if possible, decompose them.

Great weight seems to be associated with our ideas of metals. This is true of many of them, as platinum, osmium and iridium, all more than 20 times as heavy as water, the sp. gr. of the last being 22.66. Gold, lead, mercury, palladium, rhodium, ruthenium, silver, tungsten and uranium are 10 or more times as heavy as water; while bismuth, potassium, sodium and lithium are lighter than water, the sp. gr. of lithium being only .5336. A cubic inch of iridium weighs 5,720 grs., and one of lithium only 150 grs. The weight of most metals is greatly increased by hammering. Pure iron, obtained by electrolysis, has the sp. gr. of 8.14, considerably higher than the purest wrought metal.

Most of the metals are of a white or grayish color, sometimes bluish; but to this there are a few exceptions. Gold, barium, strontium and calcium are yellow, though the last is of a very pale shade; copper is red; bismuth reddish-white; antimony and platinum approach the nearest to blue. In hardness there is as much diversity. Iron, tungsten, chromium, rhodium and iridium are remarkable for extreme hardness; rubidium is as soft as wax and potassium and sodium can be readily kneaded with the fingers. Antimony, arsenic and bismuth are so brittle that they can be pulverized in a mortar. Iron is the most tenacious of all metals. Gold is the most malleable metal, as it can be beaten into leaf 1-280,000 of an inch in thickness. One grain can thus be distributed over 56 square inches of surface. Through very thin gold leaf light passes with a greenish tint. Gold and silver are remarkable for ductility. One grain of the former can be drawn out into 500 feet of wire; of the latter into 400 feet. Many metals are very refractory to heat, and one, osmium, has never yet been melted. Platinum and iridium are but little less infusible; the fusible point of mercury is, however, 39° below zero, and that of rubidium 33.5° above. Potassium, sodium and indium fuse below the boiling point of water. The most electro-positive of all metals is cesium; then come rubidium and potassium. The most electro-negative is arsenic. Several metals are volatilized by artificial heat, and some of them exhibit beautiful changes of color. Gold, yellow at ordinary temperatures, is a bluish-green color when fused, and by intense heat can be converted into a beautiful purple vapor. The vapor of potassium is of a violet; that of rubidium of a greenish-blue and that of palladium of a rich green color. The atomic weight of gold is the highest, 196; that of glucinum is the lowest, only 4.7.

BOILER EXPLOSIONS DUE TO GREASE AND LIME.—A French paper says: A commission, appointed to report on a boiler explosion at La Villette, Paris, attributed it to an insoluble deposit, composed chiefly of a calcareous soap, which formed near the opening of the water feed-pipe, and which was due to the nature of the feed-waters. Some of the water was furnished by the city, containing calcareous matters; some came from condensers, bringing fatty particles from the machines, in which they had been used as lubricants. The commissioners cite numerous accidents which have occurred during the past 15 years, all of which are attributable to the same source. They, therefore, think it important that all manufacturers should be warned of the danger, and if they are obliged to use such a mixture of waters they should use all possible precautions, such as the purification of the calcareous waters by carbonate of soda; the filtration of the condensed waters, by passing them through wool or felt; the skimming of the grease from the surface of condensing cisterns; and frequent drawings off from the surface of the water in boilers.

COLORATIONS ON ZINC.—An original recipe for giving beautiful and durable rainbow colorations to zinc is reported. The zinc may be in any form, cast or sheet, but must be pure, dry, polished, or filed, and the coloration is the more brilliant as the materials of the bath are pure, so that the best effects are got with chemically pure re-agents. The bath consists of 30 grammes tartrate of copper (weinsaures Kupferoxyd), 40 grammes caustic potash, and 480 grammes distilled water. On subjecting the zinc to the action of the bath for a couple of minutes it appears violet; for three minutes, deep blue; four and one-half minutes, green; six and one-half minutes, a golden yellow; eight and one-half minutes, purple violet.

BODY COPAL VARNISH FOR COACHMAKERS' USE.—Fuse eight pounds fine African gum copal; add two gallons clarified oil; boil slowly until quite stringy; mix with three and one-half gallons turpentine, and strain. The boiling will take four or five hours.

"Equality Country."

Mr. Ruskin has opened near Sheffield a museum for workmen. It is the first school established under the St. George's company for the workmen and laborers of England, to whom the *Fora Clavigera* is inscribed, and as soon as he had selected the site Mr. Ruskin called some of the Sheffield men together and explained to them the reasons of his choice. He was well pleased with the workmen, spoke to them in the most familiar and friendly strain, and remarked that he had come to learn and not to teach. Having found they appreciated the boon he was about to confer upon them, he has sent to the museum many rare and interesting objects. On his paying a second visit to Sheffield several workmen, who had embraced the doctrine of Robert Owen, were anxious to obtain an interview with him, especially as he was reputed to be of an exceedingly amiable and affable disposition, and to hear his opinion as to the feasibility of establishing a "co-operative village," consisting of houses, works, dining and lecture hall, library, etc., and surrounded with plenty of fresh air and pure water. Out of the funds of St. George's company he has now purchased at Ableydale, Sheffield, a beautiful estate of 13 acres, at a cost of altogether \$11,000, and has expressed his willingness to accept his co-operative friends as tenants until the annual interest they may contribute shall have cleared off the capital; that the estate is to be known as Equality Country; that 12 families have united in the undertaking, and that all their earnings will be thrown into a common stock, are matters of surprise to those who have taken a leading part in the movement. At most two families will live on the estate until it is known that the scheme is a success, the object of its promoters being simply to carry on the boot and shoe making trade on co-operative principles in antagonism to the modern system of producing, by means of machinery, cheap and nasty goods, and if in this they succeed, they may gradually increase the number of their dwellings and form the whole into a co-operative village. The garden produce will be simply to meet their own requirements, but, in whatever direction they may extend their present programme, Mr. Ruskin has not been asked to furnish them with the requisite means to carry out the movement.

FIVE THOUSAND DOLLARS REWARD FOR A NEW INVENTION.—The Directors of the London General Omnibus Company offer to award a prize of £1,000 for an invention or a scheme for effectually recording or checking the receipts of their passengers' fares, and which may be accepted by them as being so effectual. But the acceptance of any invention or scheme is to be entirely in the discretion of the Directors, who will not be bound to accept any invention or scheme at all, nor to give any reason for non-acceptance.

GOOD HEALTH.

Nervous Exhaustion.

Dr. J. H. Jackson has a word on this subject in the last issue of "The Laws of Life," which is sensible and deserving of a place here. He says:

Seek to remove, in the first place, the causes, whatever they may be, which have induced prostration. No doubt the nervous centers, from which all nervous power and force are derived, are exhausted, and where this is the case, time is required in order that their nutrition may be thoroughly re-established. Let the person then avoid overdoing, always working or taking his pleasures within the limits of any taxation of body or mind; let him secure agreeable social associates; live largely in the open air; sleep as much as possible; eat nutritious but unstimulating food, such, for instance, as is afforded by the various preparations of milk, fruits and grains, principally of wheat, so far as grains are concerned, because it contains more of the nerve-making constituents than other grain. Avoid the use of condiments of all kinds and alcoholic liquors; remembering, however, that if the person is not already accustomed to such a diet, the change must be made gradually, although positively, in order that the nervous system may not be thrown into perturbation by sudden withdrawal of its accustomed stimulation. All of the habits of life, in regard to work, exercise, pleasure, eating and sleeping, should be in accordance with a thorough regularity of action in each 24 hours. He should take two baths each week, in which the body should be washed very thoroughly with tepid water, and rubbed afterward to insure good capillary circulation.

Some of the most eminent physicians are coming to advise as the best means for a permanent cure of nervous prostration and debility, a radical change in dietetic habits, embracing the use of unstimulating but nutritious food in the place of the more stimulating articles, such as meats and condiments. By carefully following such a course, health should be restored.

OATMEAL.—Oatmeal should only be purchased at places where there is a quick sale for it, as it absorbs moisture from the air, and very quickly becomes rancid and unpleasant.

Hints on Drainage and Sewage.

Prof. Hilgard, of the State University, writes to the *Oakland Tribune* giving some practical suggestions which we doubt not will be found of value to many readers. He says: It is important to devise some means of relieving the difficulties encountered in avoiding the fearful nuisance of open gutters running with filthy water, which poisons the atmosphere in suburban districts, and bear so large a share in infecting putrid fevers, diphtheria and dysentery upon the otherwise enviable dwellers outside of city limits. The points to be observed are briefly these:

1. To keep entirely separate the more offensive—kitchen and water-closet—sewage from the cleaner run of the wash-stand, bath-tub and wash-tub.

The difficulty in disposing effectually of offensive sewage is directly proportional to its bulk and offensiveness. Hence it is comparatively easy to dispose of the undiluted kitchen sewage alone, either by running it into a small cesspool covered with from six to 12 inches dry earth or charcoal; or else into a small similarly-covered (barrel) tank, from which the solid matter is frequently removed to the manure pile, while the water runs off into a small irrigating ditch in the garden, where the loose soil absorbs and disinfected it promptly. The manurial value of this kitchen sewage is considerable, whether for flower-beds or vegetable garden.

Water-closet sewage greatly complicates the problem, both from its great bulk and its offensiveness. However convenient apparently, the water-closet is an invention of questionable benefit to mankind, from the frequency with which it gives rise to malarious diseases in the household, and the immense increase of the cost of city sewage which its use involves. It should, wherever possible, be substituted by the earth-closet. It is surprising that this simple and effectual means of overcoming some of the most formidable difficulties in the way of domestic hygiene should thus far have been almost totally ignored on the Pacific coast; at least I have been unable to find in the great city of San Francisco even an agency for the sale of the ordinary appliances for the use of dry-earth closets. Fortunately, the essential things are within such easy reach of everyone, that none need wait for such machinery to be manufactured. A rough box, say, 12 by 18 inches, by 15 inches high, mounted on truck wheels, so as to be easily discharged, will serve as a receptacle for a week in a family of five or six persons. Another box, conveniently placed and filled with dry earth, and a grocer's scoop, hung on a nail above it, completes all the really needful appliances; dry earth, not sand, is not difficult to obtain in California during the greater part of the year; for the rainy season, a supply must of course be hoarded. It should be well raked over, so as to break or remove all larger clods. The contents of the receiving box may, however, be used over and over again five or six times, after drying, which can be done in a shed, without the least offense. The whole arrangement is so simple, inexpensive, and so thoroughly effectual in removing all offense and securing complete disinfection, that few will desire to dispense with after trial; and it disposes, most conclusively, of the most troublesome part of the sewage question.

The sewage of the wash-stand, bath-tub and wash-tub, being comparatively inoffensive, and without any considerable amount of solid matter, can be easily so directed as to serve for irrigation of ground kept loose by cultivation, either through a channel from which it distributes itself, or through the garden hose. I find it very convenient to so interpose a large gauge-cock in the leaden drain-pipe as to make it possible to use the water either way, as may be most desirable or convenient.

In times of scarcity of water, like the present season, the amount of water so contained for garden use is a matter of no small consequence. It is much more than any one who has never measured it would imagine; and when the use of water for garden or lawn irrigation is of necessity restricted or prohibited, an arrangement of this kind may make all the difference between being able to maintain your improvements, or seeing all your grass and flowers fall victims to the drouth.

SUBSTITUTE FOR SULPHATE OF QUININE.—Dr. Woodworth, Supervising Surgeon-General, calls the attention of medical officers of the U. S. marine hospital service to the extraordinary increase in the market price of quinia sulphate, and at the same time to the accumulating testimony in favor of the employment of the quinia, chinchonidia and chinchonia sulphates, of which the two first named are believed to be as efficacious as the quinia sulphate. He suggests that the less costly salts be accorded a fair trial, and that medical officers take this matter in consideration in preparing their next semi-annual requisition for medical supplies.

ASPARAGUS AND RHEUMATISM.—The advantages of asparagus are not sufficiently appreciated. It is said that those who suffer from rheumatism are cured in a few days by feeding on this delicious esculent, while more chronic cases are much relieved, especially if the patient avoids all acids. The Jerusalem artichoke affords a similar relief. It may be well to remark that most plants that grow naturally near the sea-coast contain more or less iodine, and in all rheumatic complaints iodine has long been used.—*Dietetic Reformer*.

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTION IN ADVANCE.—Postage paid—one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by registered letters or P. O. orders at our risk.

WRITE FOR THE MINING AND SCIENTIFIC PRESS. We invite not only professional men, but practical miners and mechanics to contribute to our columns. All communications will be kindly treated. Authors, as well as readers, will be benefited by corresponding.

ADDRESS all letters to the firm, and not to individual members, or others, who may at any time be absent from our office.

Our latest forms go to press on Thursday evening.

SAN FRANCISCO:
Saturday Morning, May 26, 1877.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Academy of Sciences; Improved Washing Appliance; An Antiseptic Burial Casket—New Method of Embalming, 321. Reflections of the Week; Reduction of Expenses of Mining; Mining Education; Mining Speculators; Our Agents; Items of Interest From the Mines, 328. Earthquake Waves; Regulating the Flow of Water in Ditches; A Short Lecture on Patents; The Justice Investigation, 329. Notices of Recent Patents; Patents and Inventions, 329.

ILLUSTRATIONS.—Denney's Improved Washing Appliance; Snooks's Patent Water Filter, 321. Diagram Showing the Record of Tidal and Earthquake Waves at the U. S. Coast Survey Tide Gauges, Fort Point, May, 1877, 329.

MECHANICAL PROGRESS.—Uses for the New Form of Steel; Portable Electric Light; Good Forgers; Service of Steel Wheels; Testing Railroad Material; An Atmospheric Engine; Box Filing for Small Scrap; Packing Polished Sheets, 323.

SCIENTIFIC PROGRESS.—Social Statistics; Influence of Age on Leaf and Flower; A Transit of Venus Medal; "Popular Science Monthly;" Ozokerite for Preserving Metals; Prizes for Industrial Research; New Weighing Instrument; A New Chemical Element; Action of Sea Water on Lead, 323.

THE ENGINEER.—Transmission of Power by Wire Ropes; Cement and Broken Stone for Culverts; Longest Tunnel in the Union; Meigs' New Enterprises; One of the Famous Bridges of the World; Draining of the Zuyder Zee, 326.

MINING SUMMARY from the various counties in California, Nevada, Idaho, Montana and Utah, 325-32. **MINING STOCK MARKET.**—Sales at the San Francisco, Nevada and California Stock Boards; Notices of Assessments, Meetings and Dividends; Review of the Stock Market for the Week, 324.

USEFUL INFORMATION.—Facts About Metals; Boiler Explosions due to Grease and Lime; Colorations on Zinc; Body Copal Varnish for Coachmakers' Use; "Equality Country;" Five Thousand Dollars Reward for a New Invention, 327.

GOOD HEALTH.—Nervous Exhaustion; Oatmeal; Hints on Drainage and Sewage; Substitute for Sulphate of Quinine; Asparagus and Rheumatism, 327.

GENERAL NEWS ITEMS on page 332 and other pages.

MISCELLANEOUS.—The Guadalupe Mine; The Bear River Mines; Important Ditch Enterprise; River Mining; Trinity Mining Interests, 322. Some of the Mines at Ward; Electric Explorers, 326. Advertisements of Foods, 327. The Bremen Mill, New Mexico; The Sespe Oil District; Will it be Started Up? Trial of a New Lifeboat; The Georgia Gold Mines, 330.

NEW ADVERTISEMENTS.

Tolles Improved Concentrating Tables, John U. Tolles, Eureka, Humboldt Co., Nev. Assessment Notice—Silver Sprout Mining Co.

Reflections of the Week.

In some parts of this State during the past week we have had pretty good rains, which, however, did not do very much for the miners. In some parts of Feather, Stanislaus and Bear rivers the miners are at work on the river beds, the water being low enough to admit of this. Such low water has not been known for many years, and the upper part of Feather river particularly, is being wing-damed in many places where the miners are getting at the river bed. The rain spoken of above, although doing no great amount of good, will help a little to prolong the water season. The season for the hydraulic mines this year will be short, some having shut down already in some parts. In Placer county the principal claims are all washing away vigorously while the water lasts, and blasting their ground in every direction, so as to make the water go as far as it will.

There is nothing specially new to report on the Comstock, some 35 mines have shut down in that region in the past month, but others are still prospecting. The largest single shipment of bullion ever made, was made from there last week, which is something fresh to record at any rate. Mining stocks in the city show no improvement this week. The committee appointed by the Board of Brokers has issued circulars to the various large mining companies, asking information from them of their operations and expenses. It is to be hoped that facts will be elicited in this way which will have a beneficial effect on the mining interests, by calling attention to the details of expenditures, so that they can be reduced to suit the times.

Reduction of Expenses of Mining.

The depression existing in mining stocks, and the consequent falling off of profits of those interested in buying and selling them, has awakened this class to the fact that some change in the system of management is necessary. A number of brokers held an informal meeting last week and passed a resolution appointing a committee "to devise a plan to obtain an improved management of the mining interest, and to consult with the officers of those mines listed on the stock board for the purpose of suggesting some means of reducing the general expenses of mining."

We mildly suggest that it would not be a bad idea, when considering the reduction of expenses, to consult with officers of mines *not* on the stock board, for, as a general thing private mines are managed much better and more economically than those whose chief object is for stock dealing rather than legitimate mining. Those on the stock board have begun to reduce expenses at the wrong end. They have cut down expenses at the mine instead of in the office. They have discharged miners working at \$4 per day instead of Presidents at big salaries. The working force at the mine on small wages has been reduced, but not the other force in the office at large salaries. Most of them think that when expenses are to be reduced, the first thing to do is to send off a lot of hard working miners, whereas one would suppose that if legitimate mining was the object, this would be the last place for retrenchment. Without miners the mines cannot be developed, and unless it is developed there is no use in running any company at all. In some cases, perhaps, it would be well to shut down altogether, except to keep the water out, and wait for neighboring companies to develop ground in the near vicinity.

The discharge of workmen from the mines, however, while other expenses are continued, is a poor way of economizing, if they are going to mine at all. There are many little leaks through which money runs, in large companies, which could be stopped to good advantage if the managers honestly intend retrenchment; and by cutting off these expenses enough could be saved to keep as large a working force on as practicable. The discharge of workmen brings great distress among them, and does more to depress the mining interests than the lowness of prices in stocks. When people see the men discharged they begin to think the mine is worth nothing, and the impression becomes widespread. Stockholders do not often refuse to pay assessments in mines that are being honestly and economically managed, simply because they are for a while unsuccessful in the search for ore; but they are apt to refuse to be assessed if they see heavy expenses continue in every direction, except in the mine itself, where the real work ought to be done.

On the Comstock at present there are so many idle men that great distress prevails. So many mines have reduced expenses by discharging workmen, or closing down temporarily, that the whole mining interest of the section is fearfully depressed. But while this state of things continues there we have not heard as yet of any cutting down of salaries of Presidents, Secretaries, etc., at this end of the line. No case has yet come to light where there has even been a suggestion of reduction of office expenses. The salaries of some of these officials would keep a dozen or so miners' families from starving, and would aid at the same time in prospecting the mine. If they did anything for these salaries it would not be so bad, but they don't, in nine cases out of ten. Let some of these companies try and reduce the San Francisco expenses, instead of those at the mine, and the people will believe they run the mine for mining, and not for stock speculating purposes or to pay salaries to a set of favored officials.

Mining Education.

We notice in some of the English papers complaints that attention enough is not paid to the coal interests by the Science and Art Department in Mining. It is suggested that the School of Mines, Jermyn street, London, might establish and superintend a scheme of instruction for students, distributed about in the various collieries. It is found that the course of study required by the department referred to, is quite different from that required to obtain a certificate of competency under the Mines Act, and that hence the aid of the department cannot be had in supporting the kind of school needed in a coal district. The department insists on a knowledge of veins, lodes, cross-courses, ore stamping machinery, etc., of no utility to the coal miner; and seems to ignore the specialties of coal mines which figure so largely in the examinations held under the Mines Act.

From these complaints we should judge that even in England, where they have had so much more experience than we have had here, they make errors in the method of dissemination of mining information; and that the systems in vogue at present are not entirely satisfactory. It does seem as if with the large sums appropriated annually for technical education to the Depart-

ment of Science and Art, more attention should be paid to the largest and most important industry of the country. Although the miners there number over half a million there are only seven mining schools.

The lectures given before the School of Mines, Jermyn street, London, by Prof. Smyth, are excellent, and their wide dissemination by the press give them a standard character, which is recognized on this side of the water. Prof. Smyth, as Professor of Mining in the above institution, superintends the examinations of the Science and Art Department in Mining, and if the complaints are worthy of credence, he certainly has the ability to suggest suitable remedies. Even the system there, deficient as it is said to be, is far ahead of anything we have here; where, in a country with the most extensive mineral resources in the world, we have no official whose duty it is to gather information concerning them, much less impart it. The duties of the United States Mining Commissioner have devolved on the Director of the Mint, who already has more than he can attend to, and his first experiment towards his new duties, (in estimating the quantity of ore in a bonanza with its probable yield,) has not been so successful as to inspire the utmost confidence in his ability as a mining expert. The collection of information concerning the mines is almost a dead letter now, and even in the best days the official who had it in charge had great difficulty in doing anything from the meagerness of the appropriations. Then when he got all his facts together their value was impaired because it took so long a time to have them printed. When they were printed, so few copies were issued, that on this coast where they were needed most, perhaps 100 copies came to hand. As far as any trouble being taken on the part of the Government to have any official to gather and disseminate information concerning the mines, we have very little hopes in that direction. The public depend for their information entirely on the newspapers, so that the few journals making a specialty of this industry have double duty to perform.

Mining Speculators.

There are a good many people who might be called mining speculators; that is, there are several classes of them. Dealers in mining stocks are the most properly termed "speculators," and those also deserve the name who go about and secure mining claims without the most remote idea of ever working them, but intend disposing of them at a profit to others. A certain kind of these speculators, well known in every mining camp that ever was found, are those who want to "bond a mine." They are most unmitigated nuisances, and in nine cases out of ten are not what they represent themselves to be. These fellows sometimes introduce themselves as the secret representatives of certain wealthy San Francisco capitalists, who are willing and ready to advance money for development of any claim they may recommend. Again they come with flourish of trumpets and announce themselves as the agents of Eastern capitalists desirous of getting up companies to float in New York. Then again they have some friends at "the bay" who would go into a little mining speculation if it should be made worth their while, and they could get hold of a good little mine. These people almost always succeed in getting mines bonded to them for a period of three to six months, and after that is done they await new arrivals in the camp and endeavor to sell to, or take into partnership on the bond, anybody with money enough to advance something to them for board and whisky.

The miners who bond their mines to these people never get any profit, and the gain is all on one side. If the mine is actually sold on their recommendation they want the lion's share, as a matter of course. During the time in which the mine is bonded they are not at a cent's expense on the property, and work is going along all the time. If a strike is made meantime, and the mine becomes much more valuable, of course they have a better chance to dispose of it at a good price, so it is often judicious to bond a promising mine on general principles.

Lots of these speculators have neither money or friends, but of course it is difficult for miners to judge of this; although it may be stated as a fact that the more "cheek" they show and the more loudly they talk, the less credence should be given them. There are, of course, men who bond a mine honestly with the intention of enlisting the aid of capital, and this makes it easier work for the pretenders, as the miner finds it hard to judge which is which. These fellows have come to the surface in almost every mining camp of any pretensions on the coast, a new camp being naturally the best "stamping ground." Miners are always in want of capital to assist them in developing new ground and eagerly jump at any chance of enlisting its aid. They therefore naturally are glad to have any one interest himself in their mine who has a chance to meet with capitalists who might be induced to invest. Half of these people are, however, frauds, who never had any money and never will, but bond the mines because it costs them nothing and they are apt to get a good many little convenient favors done them which they would never receive, except as the supposed representatives of capital. Some of them become quite expert at the business and manage it so as to bring them in a pretty fair income—enough at least to live upon in a nomadic sort of manner.

Our Agents.

The agents of the Press who go out into the country aid us greatly in extending the circulation of our paper, and thus widen the field of its usefulness. They also do good service for the country through which they pass in noting facts of industrial progress and placing before our wide circle of readers in this and other States trustworthy information concerning the different parts of our coast territory. We have continual reason to thank our patrons for their kindness to our agents and the assistance which they render them in the prosecution of their work. We bespeak for those agents who are now in the field, a continuance of past favors. We make the following notes of the whereabouts and destination of some of our field workers.

Mr. Joseph Dimmick will visit upper Mendocino, Humboldt and Del Norte counties.

Mr. A. C. Champion labors in parts of Mendocino and Sonoma counties.

Mr. B. W. Crowell has his present field in Amador and the more southerly counties.

Mr. A. C. Knox labors in Sierra county and southward.

Mr. A. U. Strong will visit the people of Lake, Napa and Sonoma counties.

Mr. C. N. West will do good work in Santa Cruz and Monterey counties.

We trust that our friends in the counties named and elsewhere will aid our agents with notes of their doings and the progress of their localities, so that they may be enabled to furnish us with fresh correspondence full of practical notes and interesting descriptions. We ask also that they will aid them in the prosecution of their business for us, and will pave the agents' way with good words for our paper, to their neighbors whom they may meet. Our correspondence from our readers is full of kind, encouraging words concerning the value of our paper, and we can but remind all who feel friendly toward us that a word fitly spoken to one who should aid us with a subscription, will be a direct and substantial contribution to the improvement of our journal. Our aims are all for the advancement of our paper in the sphere of usefulness. Will not every reader help us to this end as occasion may offer?

Items of Interest from the Mines.

We give below items of interest from prominent mines, most of which are collated from letters of the respective Superintendents on file at the office in this city:

In the Gould and Curry the connection of the south drift 1700-foot level with the joint winze has given a splendid circulation of air, and cooled the south end of the mine. It has also cooled off the Best and Belcher, admitting of better work in both mines.

The 700 and 750-foot levels of the Justice are still developing a well defined vein of average milling ore. The drift following ore body in the 1000-foot level also shows a decided improvement in the quality of ore produced.

Belcher is hoisting and shipping daily 70 tons of ore to the Santiago mill, which will average \$30 per ton.

The Grand Prize pump handles the water with care, and sinking the shaft is progressing.

The last clean-up of the Eureka (G. V.) mine was 200 ounces of amalgam.

Crown Point has a strong flow of hot water to contend with, but the air compressors are fully equal to the occasion.

The Hackberry mine, Mohave county, Arizona, made its first shipment of bullion on the 5th, consisting of five bars, aggregating 6,208 ounces, about 700 fine, the result of five days run.

There were 768 tons of ore extracted from the Chollar last week, averaging \$24.75 per ton.

Ophir is shipping 40 tons of ore per day to the Winfield mill.

They find it very hot in several places in the Consolidated Virginia and California mines, the heat greatly impeding work.

THE ADAMS HILL MINE.—The annual meeting of this company was held this week, when S. P. Dewey, W. W. Traylor, S. P. Middleton, Wm. B. Murray and E. E. Dewey were elected Trustees for the ensuing year. J. C. Powell was reappointed Superintendent, and W. W. Traylor, Secretary. From the President's report we extract the following summary of the work done the past year: The work done has been almost entirely of a prospecting character, and though no large or continuous veins of paying ores have been hitherto found, we are satisfied from the character of the ground, and its contiguity to the "bonanzas" found in the Richmond and Eureka Consolidated on our south boundary, as well as others developed to the north of us, that we have a very valuable property, which only requires developing to make equal to the best in the district. Confident in this belief, I have instituted measures for securing United States patents to all the ground belonging to the company. The financial report of the Secretary, also submitted, shows a cash balance to our credit of \$2,362.99.

A PLEASANT OCCURRENCE.—All hands connected with this office were invited to lunch with the publishers at J. V. Webster's new Palace restaurant, No. 218 Sansome street, on Saturday, May 19. The lunch was greatly enjoyed and highly complimented.

Earthquake Waves.

At the last meeting of the California Academy of Sciences, on Monday evening last, the President, Professor George Davidson, of the U. S. Coast Survey, exhibited an enlarged drawing of the regular tidal waves, and of the recent earthquake waves that reached San Francisco bay on the 10th of May.

At Fort Point the U. S. Coast Survey maintains a self-registering tide gauge whereby a sheet of paper is drawn horizontally over rollers that are moved by clock-work. The forward movement is nearly two feet in 24 hours. Over this sheet of paper a pencil moves athwartships by the lowering or rising of the float in the float box, and the wheel-work is so proportioned that one foot movement of the tide exhibits itself as a movement of one inch of the pencil. The drawing at the Academy was four times the length and breadth of the tidal sheet; that which we present to our readers is one-quarter the length and breadth of the same sheet.

H. L. designates high water large; L. L., low water large. H. S., high water small; and L. S., low water small. The first part of the curve from A to B exhibits the regular movement of the tide from 21 hours of May 9th (9 P. M.), to 6 hours of May 10th, when the tide was rising, and thence from B to C the normal movement of the tide is exhibited in the drawing by the broken line through the rapid fluctuations of the earthquake wave. On the sheet there is an apparent irregular ebbing of the tidal waters for a few minutes, and then a sudden rise, followed by a depression, until six large waves, of about nine inches each, had exhibited themselves in the space of one hour and 20 minutes. From the 6th to the 14th we find well-marked maxima or wave crests with intermediate double maxima well-marked and undoubted.

Then at No. 15 May 10th, 4 hours, occurs an

coast we ascertain that the earthquake wave was not noticed at open ports or landings, such as Santa Barbara, Gaviota, etc.; but its effects were exhibited in such harbors as Wilmington, Cayugas, and doubtless would have been especially noticed at the mouth of the Estero Limantour, in Drake's bay. In these harbors the rapidly advancing and rising wave would be concentrated as into a funnel and rise and fall rapidly and largely. It is reported that the rise and fall was seven feet at Wilmington, not noticed at Santa Barbara and Gaviota, and 12 feet at Cayugas.

The reported shock to two vessels near the entrance to this harbor, seems somewhat problematical. The waves entered the Golden Gate say one foot high and about 10 minutes long. We were at Fort Point at the time, and with a smooth sea, could detect no change of rise and fall on the beach where a very slight surf was running.

News of the earthquake waves coming in was telegraphed to Washington a few hours after they commenced, and from their length and height it was predicted that a great earthquake had occurred at a distant place.

Regulating the Flow of Water in Ditches.

Mr. L. A. Scowden, of this city, has just received a patent through the MINING AND SCIENTIFIC PRESS Patent Agency for an improved device for regulating a uniform flow of water, which is of special interest to miners and farmers. The device is intended for automatically regulating the area of an opening through which water is drawn from a reservoir or other source, so that the quantity of water which passes through the opening will be constant and unvarying under the fluctuations or rise and fall of the water supply or source. The invention is specially adapted for gauging the quantity of water to be supplied from a ditch, river, reservoir or other source, to customers for irrigation

A Short Lecture on Patents.

(Written for the PRESS by JOHN L. BOONE.)

There are two classes of persons that never succeed in any business. One is the class of persons who propose to give something for nothing, and the other is those who try to get something for nothing. A thing is worth just as much as it costs to produce it, taking into consideration the time, labor, and material required in its production. Time and labor are more or less valuable according to the nature of the employment; a hod-carrier can be hired for two or three dollars a day, because his employment requires no great amount of time or skill to acquire. The mason, however, must be paid five or six dollars per day, because he has learned his trade after serving a long apprenticeship at low wages. Skill in any trade or profession is expensive; expensive to acquire, and expensive when retailed out by the persons possessing it. A skillful man in any trade or profession always commands better wages than one unskilled, because his services are worth more; yet there are men who would rather pay a medium price for a "botched" job than a fair price for a good job. They expect to get the benefit of skill, and especially professional skill, for about the same wages that they can hire a day laborer. This is the case with many inventors. The inventors themselves, perhaps, are not so much to blame, because the country is full of unskilled patent solicitors, who, in order to get business, advertise to work for almost nothing, and inventors frequently being short of money are tempted to employ them. Inventors thus sacrifice themselves for the benefit of patent "shysters."

The greatest danger to inventors, however, is the wholesale patent agencies. These agencies, as they are managed, can well afford to work at low rates. Boys who receive four or five dollars per week are employed to do the inventor's work, and as a consequence it is imperfectly and carelessly done. An invention, which the inventor considers of great value, is put into this mill and ground out in some shape or other

The Justice Investigation.

It will be remembered that at the annual meeting of the Justice mining company, a committee of stockholders was appointed to investigate the financial condition, as well as the mining prospects of the company. The committee has made the following report:

The committee reports that the books of the company are kept in a proper manner, and find that no exception can properly be taken to the manner in which the business of the office has been conducted.

At the request of your committee, Mr. Henry Boden, the Assistant Superintendent of the mine, was summoned from Virginia City. Mr. Boden's statements were satisfactory in every respect, demonstrating the fact that the utmost economy had been exercised in every department of the mining operations of the company; that no workmen or attaches are employed whose services can be dispensed with; that every man on the pay-rolls of the company renders actual and valuable service, and that for the great expenses incurred, the stockholders have received a greater development than is usual in mining operations.

That the great expenses of the past year have been necessarily incurred in correcting the errors of former administrations, and have also been increased in a great degree by reason of the extensive operations of the upper levels having been conducted mostly in broken ground.

Mr. Boden also reports that the necessity of these extraordinary expenses has ceased, and that no great expense for the development and working of the mine will be necessary, excepting the furnishing of new boilers and one air compressor. This expenditure will, in the end, benefit the stockholders, by increasing the working facilities, and also by a reduction in the general expenses of the mine.

The committee also reports that the Trustees of the company are individually large owners of the stock, and every cent of disbursements is measurably paid out of their own pockets; and that as far as the committee have examined,

DIAGRAM EXHIBITING THE RECORD OF TIDAL EARTHQUAKE WAVES AT THE U. S. COAST SURVEY TIDE GAUGES, FORT POINT, MAY, 1877.

undeniable repetition of the first six waves; whether this be the result of a second earthquake, or whether it be the reflex waves of the first from another shore, is a problem for further investigation. Following these waves is a series of maxima, Nos. 20 to 23, rising quickly but having broken and prolonged crests, which harmonize closely with each other. The depression is so slight as to be equal only to the incoming tide.

Thence from No. 24 to 30 the maxima are marked, and the intermediate waves are recognizable as similar between the different maxima.

The largest waves are notably from the 30th to the 33d at low water, and exhibit ranges as great as 18 inches. It will be noticed that here the crests are 60 minutes apart. The earthquake waves continued thence forward to nearly noon of May 15th, when the last one registered itself; but long before this it was evident from the irregularity of time, elevation and form, that these were reflex waves reaching, from far off limits in the ocean. In fact, it seems likely that the reflex waves commenced certainly not later than the 30th, and possibly before that.

So far as we have been able to ascertain, the earthquake at Iquique occurred on the 10th of May, at 1 o'clock, A. M., but we must await more definite information before endeavoring to decipher the readings of the tidal register. Assuming, however, that the earthquake occurred at 1 A. M., we know the difference of longitude from San Francisco is three hours and 28 minutes, and that the first indication of the incoming wave occurred at six hours and 18 minutes at San Francisco. This would give eight hours and 46 minutes for the time occupied in the wave traversing 5,200 statute miles, mainly along the shores of South and North America; at a rate of 600 miles per hour, or 10 miles per minute.

This is much greater than the progress of the earthquake wave that left Simoda, Japan, on the 23d of December, 1854, and reached San Francisco in about 12 hours, traveling at the rate of 375 miles per hour, or 6.2 miles per minute. But the great waves of that earthquake were only eight inches in height and 35 minutes apart when they reached Fort Point. In the present case we see that the main principal waves were much higher, and their crests much farther apart.

Further information may place the locus of the earthquake away from Iquique. Upon this

purpose. A box or tank is used, into the upper part of which the water is allowed to flow through a pipe or other conduit. Across this box or tank, near its bottom, is made a horizontal partition in which at some suitable point is an opening of any desired shape. Mr. Scowden then takes a float from which is suspended a tapering or conical rod. This tapering rod is made to correspond in form with the shape of the opening and it is suspended from the float so that its largest end will be downward, or furthest from the float.

Now, when the float rests upon the surface of the water, the rod will pass down through the opening and leave only a space around the rod for the water to pass through. As the water rises the float is carried upward, so a larger diameter of the rod is brought opposite the opening, thus decreasing the area of the space or water passage as the height of the water and consequent pressure increases, so that the same quantity of water will pass through the reduced opening on account of the increased pressure as passed through the larger opening under the reduced pressure. Thus as the water rises or falls, the size of the opening or area of the water passage is enlarged or reduced in a reverse ratio; thus providing an automatic adjustment of the conical rod so as to provide a continuous flow of water of a uniform quantity under the varying pressures produced by changes in the level of water in the tank.

The tapering rod is usually suspended from the float by means of a screw rod, which forms an extension of the rod and projects upward from its smallest end. The float is then secured upon this screw rod so that it can be adjusted up or down as desired to give a greater or less flow of water. The upper end of this extension rod projects sufficiently above the float to pass through a hole in the top or cover of the box by which it is guided, and the position of the float maintained. The chamber below the partition receives the water after it descends through the water opening, and from this chamber it passes out at one side of the bottom through an opening and thence over a dam or weir, which indicates the quantity or flow by the depth of water over it. This provides an extremely simple device for regulating the area of the water passage automatically so that a constant and uniform quantity of water will pass through it at all times, independent of the height of the water in the box and the consequent pressure.

—no matter whether the patent is what it should be or not; it is a patent, it has a picture of the patent office on it and is signed by the Commissioner, and three-fourths of the inventors are satisfied just because they are in ignorance of what they really get. If it ever comes to the test of law they find out that they have nothing of value, and then they must pay a double price to have the patent reissued. If the invention does not go into public use, or the patent into the courts the patentee will possibly never know what a worthless patent he has. A party recently speaking of these Eastern wholesale agencies, said: "They run their patents out in mile lengths and cut them off to order." These agencies advertise that they charge a uniform fee for all cases; that is, they charge as much for preparing the papers and procuring a patent for a clothes-pin as they do for a threshing machine. How absurd such a proposition. As well might a blacksmith propose to iron a wagon for the same price that he would shoe a horse for. As well might a mason propose to build a brick house for the same price he would build a brick chimney for. These are incongruities that at once strike the mind as preposterous; yet they are the same thing in reality. "Poor pay, poor peach" is the motto, and,

Sugar-coat it as we will,
It still contains the same old pill.

While the inventor should be careful not to hire a solicitor simply because he is cheap, and will undertake to get him a patent(?) for a small amount of money, I do not counsel extravagance. The inventor need not depart from the usual rules of business which allow a man to settle with his attorney upon a price beforehand, so that the agent will know what he is to get for his work while the inventor knows what he is to pay. Each transaction should have its own basis, and the inventor should put himself into position to demand good and skillful work. In my judgment no person should be allowed to practice as a patent solicitor without first being examined as to his qualifications, and should be refused the privilege of practicing if found incapable. If admitted, he should be held responsible for a strict and faithful performance of his duties. Such a regulation would save thousands of dollars to the inventors of the country; first, in preventing them from spending their money for worthless patents, and secondly, from useless litigation based upon patents that will not stand the test of legal investigation.

economy seems to have been exercised in every part of the mechanical and business departments of the company.

As Mr. Boden, the Assistant Superintendent, assures the committee that the ore body in the lower level is solid in its character, and improving in quality with a promise of increasing richness, and that in a very short time this level will be fully opened, it is evident that patience on the part of the stockholders will demonstrate the fact that their faith in the Justice mine has not been misplaced in the slightest degree.

BULLION YIELD FOR APRIL.—The gross bullion yield of the mines during the month of April was as follows:

Belcher.....	\$ 65,400	Leopard.....	7,000
California.....	1,558,700	Leeds (Utah).....	27,400
Chollar-Potosi.....	67,300	Manhattan.....	88,000
Con. Virginia.....	1,142,000	ModocCon(InyoCo).....	82,100
Empire (G. V.).....	14,900	New Coso (InyoCo).....	97,200

The following show an increase over March: Chollar-Potosi, \$20,000; Con. Virginia, \$625,000; Idaho, \$14,000; Justice, \$28,000; Manhattan, \$4,400; Modoc Con., \$3,000; New Coso, \$7,000. All the other mines show a decreased production for the month.

BULLION SHIPMENTS.—Since our last issue shipments of bullion from prominent mines have been as follows: Northern Belle, May 15th, \$12,438.06; Grand Prize, 16th, \$8,300; Modoc, 17th, \$7,270—total to date \$59,520.10; Northern Belle, 17th, \$12,340.09; Con. Virginia, 19th, \$234,933.66—first shipment for May account; California, 19th, \$322,841.78—total to date, \$714,389.46; Leopard, 18th, \$5,800; Arizona, \$2,660; Grand Prize, 21st, \$8,600; Modoc, May 21st, 233 bars, value, \$6,624.61—total to date, \$66,151.78; Northern Belle, 20th, \$18,018.99; Grand Prize, 19th, \$8,525.31.

We have received a very fine box of cherries from Dr. Strentzel, Alhambra ranch, Contra Costa county. The doctor is famous for his fruit, and also for his courtesy in remembering his friends in the city.

LEAD has fallen in England to £21 2s 6d to £21 10s for good ordinary brands.

The Bremen Mill, New Mexico.

The *New Mexico Herald* says: The Bremen mill, which is now completed and in successful operation, is as perfect as human ingenuity and mechanical skill can make it. It was rebuilt under the immediate supervision of Mr. Charles Davis, who has proved himself an adept, not only as the constructor of quartz reduction machinery but as a thorough and economical manipulator of ores. The chief aim in building this mill was to obtain the largest working capacity at least possible cost, and in that regard it is most acceptable to its owner. It is run by two engines, situated in opposite ends of the building, which is 106x80 feet. The 50 horse-power engine runs 11 pans and four settlers. The other, a 35 horse-power, gives motion to 10 stamps, a pulverizer and two jaw-crushers. The pulverizer is from the shop of Hendrie Brothers & Balthof, Central City, Colorado, and will crush as much ore with less power and do better work than a 10-stamp battery. All this immense machinery moves with the utmost regularity and without a perceptible jar, and so silently do the engines perform their work that the eye alone detects the motion. The larger of these engines and accompanying boiler was built by Fraser, Chalmers & Co., of Chicago. The other is the work of a Racine, Wisconsin, company, and both do credit to their constructors. Nearly all the castings, wheels, pulleys, shoes, dies, stamps, stamp-heads, etc., were made here in Bremen's foundry, by Robert Healy, molder. The internal arrangement is roomy and complete, has a floor and bins capable of holding a thousand tons of ore, a pulverizing room 13x15, sufficiently close to confine the dust; a room 11x15 for cleaning amalgam which contains a pan with mullers and which washes and frees the amalgam from all extraneous matter.

The fall from battery to pans and settlers is 18 feet. The settlers are some feet lower than the pans, and on the lower level is a retort and refining furnace. The retort is capable of holding 1,800 pounds of amalgam. Wet crushing is the process here—although ore for the ball crusher is first dried in pans and after the ore is reduced to impalpable powder it is amalgamated wet, same as that from battery. In the north engine-room is a Knowles four-inch pump, which supplies necessary water for mill and the immense tanks on top of building, a precautionary measure in case of fire. To this pump is a rubber hose of sufficient length to reach any part of the mill and when necessary can throw a stream over the entire roof sufficiently large to deluge the fiercest fire.

Five cords of wood is quite sufficient to run the mill 24 hours and 13 men only are required to operate it. Its capacity is 20 tons. The ore handled here is of an excellent quality, and all from Bremen's 76 mine, which is only about one mile and a half from the mill and is reached by an excellent wagon-road. Were this mine as at present developed, worked to its full capacity it would supply two such mills with ore.

In connection with the mill it is the intention of Mr. Bremen to erect an extensive foundry and will build a furnace or furnaces for smelting iron ore, which in this vicinity, is everywhere abundant, and carries at least 70 per cent. of metal, and whilst this is a fact, heretofore all pig metal has had to be brought from the States and hauled in wagons after leaving rail transportation 700 or 800 miles. When this last undertaking is in successful operation Mr. B. will be able to supply all demands for castings of every class and kind.

We are glad to chronicle such enterprise, it speaks well for the producing capacity of the country.

The Sespe Oil District.

A correspondent of the *Los Angeles Express*, writing from Sespe oil district, Ventura county, says:

So little seems to be known about this district that I thought a few lines on the subject might find a space in your valuable paper. The Sespe district has an area of about 32 miles, its initial point being the Cienega post-office, to which letters for the district should be addressed. The Sespe claim, so far, I believe, the only one yet patented, is in the heart of the district, about 60 miles from Los Angeles, and can be reached in one day from there, via rail to Newhall station on the Southern Pacific railroad, thence by road about 23 miles to the Los Angeles oil claim, which with several others, belongs to a company in Los Angeles, of which Mr. Patrick is President; the remainder of the distance, some five miles, has to be accomplished on horseback over a good trail. We believe that in a short time the wagon road will be completed right through to this part of the district where the Los Angeles company hold the rest of their claims. A very good line can be obtained, and the road could be finished almost without a charge of powder. A large number of claims have been located, more particularly around the Sespe claim. The Star oil company have got possession of a number, the Recorder of the district informed me yesterday that he had filed in 110 deeds for them, and as each deed would represent probably 20 acres, some estimate may be formed of the large extent of country they command.

The southern line of the Sespe oil claim is intersected by a finely wooded canyon running in an easterly direction, through which flows, not a "babbling brook" of sparkling limestone water, of which, by the way, there is plenty up here, but a dark steady stream of fine oil con-

densed more or less by evaporation, whose origin is to be found in numerous springs that dot the sides of the canyon. Hundreds of barrels of oil are here running to waste; at least 20 barrels a day on this claim alone are lost for want of a road or pipe to transport it away. All this oil flows spontaneously; none of it is the result of development of the springs from which it flows. There are numbers of other springs, though no claim shows so many as the Sespe, where the oil is in a like manner running to waste, and I think I do not exaggerate in saying that in the district there are 200 barrels a day running away. Further up the above mentioned canyon, in the Sespe claim, a reservoir about 10 feet square has been cut into the side of the canyon close to the oil stream, it is full of splendid oil, so good that, without refining, it burns excellently in a lamp. All the oil in the district is more or less of the same quality. All that is wanted to develop this region is a little capital. People as yet do not seem to appreciate the vast wealth that must accrue to southern California from this and the San Fernando district, and it will be a good thing for those who have an interest here when a little capital, employed in boring, has shown the vast amount of oil that is stored up here. The country around here is intersected by beautifully wooded canyons with clear streams of limestone water, for the water is clear though in most instances oil floats on the top.

Will it be Started Up?

Several weeks since we announced upon what we believed to be good authority, that negotiations were pending for the purchase of the Star Spangled Banner mine. Of late we have heard nothing about it. Has the project been abandoned? We hope not, for we feel confident that that mine, if properly developed, and economically managed, can be made to pay handsome dividends. There is no question about its being a fine piece of property, and that somebody will make a big thing out of it. As near as we can remember something like \$900,000 was taken out of the mine, and when the company quit work they had a six-foot ledge in the bottom of the 620-foot level, which paid \$12 per ton, but by some unaccountable mystery it cost \$13 per ton to mill it, and then they gave up the work. The mill, hoisting works, etc., were sold to the Nevada foundry, and not a day's work has been done on the mine for eight or nine years, and yet the people who are posted declare that it will yet be a leading mine in this district, and with that belief it seems strange that a company can not be formed for the purpose of opening it up. Everything is cheaper than it was at the time the works were closed down, and the quartz prospects in that immediate vicinity are showing up well. Then why should the Banner not be worked? The North Banner, the extension of the Star Spangled Banner, has a fine looking ledge which is about one and a half feet thick, and several experts who have examined it assert that it is a No. 1 prospect for a big mine. It is estimated that it would cost about \$20,000 to buy the mine and put it in a condition to take out rock. It appears to us that amount is very insignificant to raise when the real value of the mine is taken into consideration. We contend this piece of property is well worthy the consideration of capitalists, and the prosperity of the town would be greatly enhanced if it was started up. —*Nevada Transcript*.

TRIAL OF A NEW LIFEBOAT.—A lifeboat, constructed on a new principle, was publicly tried on Wednesday last, in the harbor of Cowpen Quay, Blythe, in the presence of a large number of people. The inventor of the boat is Mr. George Milburn. The new craft, which in appearance is yawl-shaped, is 15 feet long, four feet six inches broad, and its extreme depth is three feet eight inches. It is fitted on deck with a cabin, into which persons, in case of necessity, will descend by means of a man-hole door, where they will be able to securely lock themselves in until picked up by a passing vessel or till the land has been reached, in addition to being provided with a sail and steering apparatus; oars are also placed on board, so that when the weather turns out favorable, pulling may be adopted. Compartments for provisions and fresh water are placed at each end, and, in addition to carrying eight men, who form its ballast, the boat, as at present constructed, will also carry sufficient food to serve them for four or five weeks at least. The trial, which had been announced for 6 o'clock, commenced shortly after that hour, when Mr. Milburn, the inventor, and three boys fastened themselves in, and the boat was at once turned over by means of ropes. Almost immediately she righted and rose on the wave. Another trial with three able-bodied men and the inventor was shortly afterwards made, when the boat, as was expected from the increased weight she contained, rose still swifter to the surface than she had done before. —*Iron*.

THE GEORGIA GOLD MINES.—The Gainesville Southern has the following: "The mines in and around Dahlonega are now all in active operation, although the mining work, being mostly in open cuts, has been more delayed by storms and bad weather than ever before since they started. Work on the new 20-stamp mill at the Hand company mine is already commenced, and that an addition of 10 stamps to present mill is contemplated. This would make 50 stamps at the Hand mine, and would largely increase the amount of gold receipts with a small corresponding expense.

Superior Pianos for the People at Popular Cash Prices.

More than TEN THOUSAND prosperous families on this Coast need Ten Thousand GOLDEN PIANOS to make TEN THOUSAND HOMES MORE PLEASANT AND ATTRACTIVE.

Prices of good Pianos have long been too high. Our people could not afford to buy them. But many will find it not only pleasant but profitable to purchase

The Brilliant and Durable GOLDEN PIANO

Which we now offer the readers of this paper

At Greatly Reduced Popular Cash Prices.

We Guarantee them to be as represented, of superior tone, finish and durability.

Samples can be seen by calling at this office. We keep no expensive sales-rooms and attendants.

We shall sell none but superior and desirable instruments, but give our customers the benefit of prices far below any before offered on this side of the Continent.

Prices of the Golden Piano:

	The Installment Plan Prices.	Our Reduced Cash Prices.
The Golden Piano, \$500	\$500	\$350
(UPRIGHT—C.)		
The Golden Piano, \$375	\$375	\$300
(SQUARE—No. 1.)		
The Golden Piano, \$500	\$500	\$350
(SQUARE—No. 2.)		
The Golden Piano, \$600	\$600	\$400
(SQUARE—No. 3.)		
The Golden Piano, \$800	\$800	\$450
(SQUARE—No. 4.)		

We invite our readers who wish to look at Pianos for themselves or friends, for immediate or future purchase, to call and examine our samples.

Those who cannot call will be supplied with further descriptions and recommendations by sending to this office.

DEWEY & CO'S SCIENTIFIC PRESS Patent Agency.

Publishers, Patent Agents and Engraver,
224 SANSOME STREET, SAN FRANCISCO.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quick-silver. 1876.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$2.50 coin, or \$3 currency, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers, containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also contains throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE, \$7.50.

Contents of Pamphlet on Public Lands of California, U. S. Land Laws, Map of California and Nevada, Etc.

Map of California and Nevada; The Public Lands; The Land Districts; Table of Rainfall in California; Counties and Their Products; Statistics of the State at Large.

Instructions of the U. S. Land Commissioners.—Different Classes of Public Lands; How Lands may be Acquired; Fees of Land Office at Location; Agricultural College; Scrips; Pre-emption; Extending the Homestead Privilege; But One Homestead Allowed; Proof of Actual Settlement Necessary; Adjoining Farm Homesteads; Lands for Soldiers and Sailors; Lands for Indians; Fees of Land Office and Commissioners; Laws to Promote Timber Culture; Concerning Appeals; Returns of the Register and Receiver; Concerning Mining Claims; Second Pre-emption Benefit.

Abstract From the U. S. Statutes.—The Law Concerning Pre-emption; Concerning Homesteads; Amendment Act Concerning Timber; Miscellaneous Provisions; Additional Surveys of Land for Pre-emption, List of California Post Offices. Price, post paid, 50 cts.

DEWEY & CO., Publishers, S. F.

French Savings and Loan Society,

411 Bush Street, above Kearny, SAN FRANCISCO.

G. MAHE, Director.

Continued from page 325.

BEUCHER.—Daily yield, 80 tons of ore. Sinking the main incline is making good progress. Sinking the drain shaft is also going steadily forward.

OPHIR.—Daily yield, 30 tons of ore. The opening of the 1900-ft station is making good headway. The flow of water at that point has decreased until it gives no trouble whatever now.

CHOLLAR-POTOSI.—Sinking the Combination shaft is going steadily forward, the bottom in good blasting ground.

IMPERIAL CON.—The north drift on the 2135-ft level is still advancing toward the Alpha line, the face in very favorable ground.

UTAH.—The southeast drift on the 1150-ft level has cut through the wall of the ledge and is now running in dry, solid vein matter.

HOMESTEAD.—Work in the shaft has been suspended for the past month on account of making certain necessary improvements on the surface, which are now nearly completed.

HALE & NORCROSS.—The repairs to the cave in the main incline below the 1900-ft level are about finished. The water is now reduced to a point 63 feet below the 1900-ft level.

MORNING STAR.—Sinking the main shaft is being pushed vigorously downward.

ALTA.—The opening of a station for the purpose of drifting for and prospecting the ledge is soon to be commenced.

DAYTON.—The ore bodies on both the 400 and 220-ft levels are opening up much better than was at first expected. Arrangements are being made for milling the ore.

SAVAGE.—The pumps are kept steadily at work, and are gradually gaining on the flow of water, even while running at a less rate of speed than heretofore.

SUTRO TUNNEL.—Total length of tunnel, 16,827 feet; face in hard porphyry, with streaks of quartz and clay coming in, showing a change for the better.

ELY DISTRICT.

ALPS MINE.—Pitche Record, May 19: The usual amount of ore is being taken from this mine; the prospect in the winze on the 204-ft level is very encouraging. The Condr mill continues running night and day on Alps and custom ore. The Alps mill will start up as soon as sufficient water can be obtained to run it regular. The prospect of getting this water appears very good at present.

PICHOE BULLION.—Bullion shipped by Wells, Fargo & Co. during the past week, being the product of ore from this district, amounted to \$10,517.73.

RAYMOND & ELY.—Considerable good ore is being extracted from the upper levels, and developments on the 1200-ft level are looking better as work progresses. The strata lying along the hanging wall shows a ledge of four feet in thickness, but where the ledge is run through by cross-cuts, the ledge matter is much wider. Much of this vein is of the finest character of quartz containing gold. The ore that is silver is richest in gold. One assay showed as high as \$37 in gold, while others went \$30, \$12 and \$10 in gold. Captain Day, the Superintendent, thinks this a splendid prospect, and has no doubt of it improving rapidly, as it has done heretofore as the work progressed. The last assay, made yesterday, went \$207.63 in silver and \$72.73 in gold.

BULLIONVILLE FURNACE.—The Bullionville furnace has been leased by Osborne & Co. for the purpose of working the concentrations at the Dry Valley mill. McCormick, a banker at Salt Lake City, has telegraphed word that he has sent a man from that place to do the smelting, one that understands the business thoroughly, so then the furnace will soon be to work and will be of immense benefit both to Bullionville and this place. The process of shipping the concentrations to Utah was entirely too slow to make it a paying business.

EUREKA DISTRICT.

THE ATLAS FURNACE.—Eureka Sentinel, May 14: As most of our readers know, the Atlas is running on Hamburg ore, the smelting company, in fact, taken a lease of the Atlas works. The furnace was fired up a few days ago, and is doing splendidly. There is on hand 824 tons of ore and 22,000 bushels of coal. From 45 to 50 tons daily are being put through the furnace. Yesterday's shipment consisted of 190 bars, weighing 20,060 pounds. Everything is moving along in excellent shape.

Idaho.

GOLDEN CHARIOT.—Owyhee Avalanche, May 19: The Golden Chariot is wearing a more promising look than ever. The 13th level is now in 325 feet. The vein matter has changed somewhat in appearance recently. It exhibits more mineral and has a more healthy indication as the work progresses. All the signs here are propitious for the opening up of a magnificent bonanza at this level. As a result of the systematic and well-directed operations that have been in progress in this mine for the past few months, the existence of three promising veins, east of the Chariot, viz.: The middle vein, Crane & Driggs, and the East Side is now very clearly defined, and each is contributing its quota to the general yield of the mine. Quartz hauling has commenced and the mill is crushing away at a lively rate.

The Belle Peck is looking splendid again, and the work is being carried on both night and day. Rich rock is being taken from the ledge in the lower levels, and now that the water is being kept at bay, everything in and about the mine has a promising appearance. The pay streak is from two to a half foot wide.

The operations at the Empire and Belle Peck give increased interest and importance to the expected developments at the Poorman, where the great bonanza of that section of War Eagle mountain undoubtedly exists. A few weeks judicious and well directed labor in the Poorman would open up the real source of wealth in that promising mine.

Operations are being vigorously prosecuted in the Potosi, where the workmen are sinking a winze about 40 feet below the main tunnel level. This operation will enable them to take out about 300 tons of very rich ore.

Montana.

ORE.—Butte Miner, May 12: Two men are working on the Lena mine, taking out some very high grade ore, as saying from 400 to 1,400 ounces per ton.

DEVELOPMENT was commenced yesterday on the Little Darling lode. The surface ore sample 63 ounces; it holds good the extraction of ore will continue until a 25 or 30 ton shipment is piled upon the dump.

Work is progressing very favorably on the Uinta mine. Several tons have been sent to mill to get at a correct sample of the ore now being taken out of the mine.

Last week we mentioned that a small lot of ore from the Friedland lode, owned by Messrs. Roubush & Young, was to be crushed in the Burlington mill as a test of its value. The result was quite satisfactory, the ore running up to something over 40 ounces per ton in silver, and saving a high per cent. of the assay, showing that the ore contains very little base metal and can be profitably mined and milled.

Utah.

DRY CANYON.—Cor. Salt Lake Tribune, May 19: The mines are all looking well. The Hidden Treasures employ from 90 to 100 men, and is shipping large quantities of ore. The Herschel, owned by Spangler & Keller, bids fair to become one of the leading mines of the Territory. The Mono is retimbering, and intends putting on a new force of 50 or 60 men. The Josephine has commenced shipping ore. In fact, the mines are doing a prosperous business, and everything seems to warrant lively times for the next six months and a permanent prosperity for the camp.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

PATENTS AND INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

(FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.)

FOR WEEK ENDING MAY 15TH, 1877.
190,685. FRUIT DRIER.—H. Kelly and D. Cole, East Portland, Ogn.
190,690. PILE DRILL.—I. Piles, Yankton, D. T.
190,771. MACHINES FOR PUNCHING AND SHEARING METALS.—A. Lee, Forest Grove, Ogn.
190,794. HOP DRIERS.—S. R., J. C. and J. H. Templeton, Brownsville, Ogn.
190,806. HORSESHOE BAR.—A. Barton, Nevada City, Cal.
190,808. ORE WASHER.—D. Beaumont, Sacramento City, Cal.
190,928. BLOWING MACHINE.—T. A. Cochran and J. Hendy, S. F.
190,840. GANG EDGERS.—D. Evans and W. Snyder, Salm-on Creek, Cal.
190,911. WATER REGULATOR.—L. A. Scowden, S. F.
190,919. EFFLUVIA EXTRACTOR FOR WATER-CLOSETS.—W. Smith, S. F.
190,923. ROTARY ENGINES.—T. F. Sparrow, Denver, Col.
7,679. SLOP-HOPPER.—J. Marquis, S. F.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

BLOWING MACHINES.—Joshua Hendy and Thos. A. Cochran, S. F. This invention relates to certain improvements in that class of blowing machines in which one or more radial vanes are secured to a cylinder or axial shaft inside of a cylindrical case or shell, and in which a rotary abutment is used for closing communication between the air inlet and exhaust passages; said rotary abutment being provided with a longitudinal recess in which the vanes are received and passed from one side of the machine to the other. In blowing machines of this class the rotary abutment is operated by a gear connecting with the main shaft in such a manner that the outer ends of the vanes will successively enter the recess in the abutment at the proper instant, while the rotation of both will allow the vane to pass from one side of the machine to the other and at the same time preserve a sufficiently air-tight joint between them. Heretofore the vanes have each been made in a single piece which would not yield to any irregularity of the cylindrical movement. The machine was therefore liable to be broken or rendered useless by the natural wear upon the parts. This difficulty is remedied in the invention by constructing the vanes in two parts, so as to allow them to yield to any irregularity of motion. Other improvements are also provided which render this class of blowing machines more durable and reliable than heretofore.

HORSE-SHOE BAR.—Arthur Barton, Nevada City, Nevada Co. This is a compound iron and steel horse-shoe bar, which is so adapted and combined that when the bar is bent or formed into a horse-shoe, the iron will form the upper part of the shoe, or portion which comes next to the foot of the horse, while the steel forms the wearing surface or lower part. The steel portion or sole is only about half as wide as the iron portion, so that it will form when welded to the bar the proper outline for the base of a horse-shoe. When this bar is bent into the proper shape, this steel ridge or sole will form a wearing surface for the shoe, while the iron portion comes next to the horse's foot; the steel can then be hardened as much as desired, so as to form a shoe of great durability and one which is much cheaper and easier made than an entire steel shoe. By making the upper inside edge of the shoe inclined or beveled towards the center of the shoe, any dirt which may get jammed in between the horse's foot and the shoe will be displaced by the jar of walking and will readily fall out.

PHOTOGRAPHING.—We have received a number of fine views taken by Mr. S. P. Sanders, photographer of San Jose. We learn also that Mr. Sanders has decided to visit some of the prosperous towns of the State this summer, and has chosen the somewhat novel manner of taking pictures in a tent. It will be commodious, cool and airy, and a great improvement over the small cars which are sometimes the only local accommodation afforded our country friends. Mr. Sanders takes with him some three hundred select stereopticon views, which he sometimes exhibits, and which will repay any one who embraces the opportunity of seeing them. We have known Mr. Sanders since 1862, and can recommend him as a competent artist and a worthy and reliable gentleman.

THE starting of the Richmond and Eureka Con. smelting works on the 1st is announced on reliable authority. Both companies have developed large bodies of ore outside of the ground in dispute.

THE largest single shipment of bullion ever made from the Comstock was made on the 19th inst., consisting of 150 bars of bullion, valued at \$568,720.81.

THE sales of the San Francisco Stock Board last week amounted to \$1,400,000.

Coast Railroad Items.

Over 2,000 men are at work on the railroad between Bantas and Oakland, and the amount of money paid out for labor alone on this enterprise exceeds \$80,000 per month. The work will be finished within three months.

The controversy between the city of Stockton and the Stockton and Visalia Railroad Company has been settled. The city has agreed to pay \$200,000 of the bonds, the remainder—something like \$500,000—being destroyed.

The Contra Costa Gazette of Saturday says: On Wednesday last ten miles of the rails had been laid from the junction of the Western Pacific toward Antioch; and as they are being laid down at the rate of about a mile a day the locomotive of the construction train will doubtless be at Antioch before the close of the month.

The Alameda Independent says that the South Pacific Coast Railroad Company, or the men who control that company, have secured from the authorities of the town of Alameda the right of way through that town for a narrow-gauge railroad to be built in a southerly direction, so as to connect at Newark with the railroad already constructed from Dumbarton Point to Santa Clara and San Jose. They are required to expend \$30,000 within six months on it and to complete six miles of the road within one year.

Articles of incorporation of the Fulton and Guernville railroad have been filed, the object being to construct and run a railroad from Fulton station, on the line of the San Francisco and North Pacific Railroad, in Sonoma county, to Guernville in the same county. The capital stock is \$675,000, divided into 6,750 shares at \$100 each, and the directors are Peter Donahue, Edward Martin, Michael Reese, Thomas J. Bergin and Patrick E. Dougherty. Peter Donahue is President, Michael Reese, Vice-President, and Patrick E. Dougherty, Secretary.

The annual meeting of the Eureka and Palisade Railroad was held at Eureka on the 21st. The company have decided not to extend the road southward this season.

Important to Miners.

J. A. Williamson, Commissioner of the General Land Office, in reply to an inquiry made by A. C. Fisk, of Denver, Colorado, has rendered a decision of the highest concern to all who are engaged in mining upon the public domain:

"In the case presented by Mr. Fisk, where a party discovered a mine on the 1st of July, sunk a discovery shaft ten feet in depth, and made record of his claim on the 28th of August, 1876, the first annual expenditures should be made prior to July 1st, 1877."

The above decision is important, and the following requirements and conditions result therefrom:

First. The date of the beginning and origin of the title to a new lode claim will be the exact day on which it shall be first discovered by the uncovering and disclosing of the same.

Second. The recorded location notice (or certificate) should, in all cases, state the date on which the discovery was made.

Third. The time in which annual expenditures must be made will begin and end yearly on the date of discovery, not on the date of record.

Fourth. The work of sinking the discovery shaft ten feet deep, or said portion of said work as shall be performed after the date of discovery, may be accounted as part, or a whole (as the case may be), of the first annual expenditure.

Fifth. Claims located prior to January 1st, 1872, are not affected by this ruling. The law of Congress requiring annual expenditures not having gone into operation until that date, claims located prior thereto were given a full year to do their assessment work; that is to say, that these old titles may be represented at any time in the year, between the first day of January and the last day of the succeeding December.

THE Postoffice Department gives notice that the schedule days of departure from San Francisco of mails for Japan and China, have been changed, and the number of trips increased as follows: The Pacific Mail Company will dispatch its steamers from San Francisco, May 29th, June 20th and July 14th. The vessels of the Occidental and Oriental Company will leave the same port on June 9th, July 3d and July 27th. Increased frequency of trips will continue throughout the season.

The bullion shipments from the Benton office of Wells, Fargo & Co., during the month of April, amounted to the value of \$53,921. Mono county must be looking up.

A MINER named James Bailey committed suicide at Virginia City last week, by jumping down La Plata shaft, 150 feet deep.

JOSEPH T. GOODMAN, has been proposed for membership of the San Francisco Stock and Exchange Board.

A LOT of 16 tons of ore recently arrived from the Silver King mine, Arizona, was sold for \$2,449 per ton.

CAPTAIN MARTIN WHITE, of the Martin White mining company, Ward district, Nevada, has gone to China.

General News Items.

AN entire row of wooden buildings were destroyed by fire at Chico, Butte county, on Tuesday last.

NINE persons were crushed to death while launching the steamer *Saratoga* at Chester, Pennsylvania, on Tuesday.

ABOUT 16,000 men are already locked out from the Clyde ship-building yards. The Clyde shipwrights at a meeting resolved to submit their dispute with the masters to arbitration.

THE New York Herald's London special says: The Chinese question is looking up. A shipload of Chinese laborers is expected in London, and an immense Chinese laundry is to be established in Holland park.

THE Postoffice Department has contracted with J. K. Warren, of Albany, Wisconsin, for mail service between Paddock, Nebraska, and Custer City, in the Black hills. This will make six mail routes in the Black hills.

NEWS is received of the total destruction of the town of Creswell, near Plymouth, North Carolina, by fire, on Friday night. All the mails in the postoffice were consumed. But little insurance was held by the property-owners and the greatest distress prevails.

ADVICES from Peru to the 28th, state that an uneasy feeling prevails in financial circles, and fears of a crash were entertained. Senor Pedro Bernales, the banker and merchant had failed for a million and a half soles, and the associate banks were thought to be in a precarious condition.

GENERAL SHERIDAN proposes to send an expedition to the scene of Custer's fight with Sitting Bull, for the purpose of getting the remains of the gallant band who were massacred upon that occasion, and giving them burial with proper military honors, at such a point as may be designated by the War Department.

SECRETARY SHERMAN is pleased with the New York Custom-house investigation, and will probably repeat the experiment at Philadelphia and Baltimore. A great reduction of force is everywhere expected. A new Naval Surveyor and Appraiser will probably be appointed at New York.

At a coal meeting in New York, on Monday, all the companies were represented, and every one present voted to suspend mining from June 15th to July 15th, with the exception of Mr. Hoyt of the Pennsylvania Company, who did not object to the arrangement, but declined to vote for it.

The Bozeman Courier of the 8th contains the annexed: Barney Hughes, the noted Mormon prospector, has reached Camp Brown, Wyo., badly wounded by Indians. He and his five partners were attacked on the Badwater on the 16th ultimo, and two were killed and three are missing.

The boot has been most decidedly changed to the other leg at the Wamsutta mills, in New Bedford, Mass. A little while ago the strike was in full blast, and all the machinery was still. Now the managers of the mills daily reject over 100 applicants for work at the old rates.

THE forty-seventh call for the redemption of 5-20 bonds of 1865, and consols of 1865 was issued on Monday. It is for \$6,000,000 of coupons and \$4,000,000 of registered bonds, instead of \$7,000,000 of coupons and \$3,000,000 of registered bonds, as originally intended. The principal and accrued interest will be paid at the Treasury at Washington on and after the 21st of August, when interest will cease upon the bonds.

THE Secretary of the Interior to-day issued an order requiring cash reports of receipts, disbursements and balances to be made to him weekly, by all disbursing officers and other agents of the department in Washington and throughout the country. The order is issued with the two-fold purpose of exercising more intelligent supervision and affecting a control of business expenditures, and with a view to preventing the perpetration of clerical or other errors.

THE GRAND PACIFIC HOTEL.—Such a thing as occurred at the Southern Hotel, in St. Louis, where thousands of dollars worth of property was destroyed and several lives lost, would not be apt to happen at the Grand Pacific in Chicago. The features for security against fire are exceptional. The construction is such that it will be impossible for a fire to extend beyond the small section in which it might originate. The fire electric system is adopted, furnishing instant alarm from all rooms. Four standing pipes of iron connect with the steamers at the sidewalk. By its own watchman alone the whole hotel could be flooded in a few minutes, and in all these features the hotel has been guarded carefully against fire. These, with the first-class appointments of the house, make it a favorite with the traveling public.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. THARP—San Francisco.
B. W. CROWELL—Amador, Placer, Calaveras and Tuolumne counties.

G. W. McGRAY—United States.
C. K. KNOX—Plumas, Sierra, Lassen, Placer and Nevada counties.

C. N. WEST—Santa Cruz, Monterey and San Benito counties.
A. C. CHAMPION—Sonoma, Marin and Mendocino counties.

A. U. STONE—Lake, Napa and Solano counties.
E. T. PLANK—Dakota Territory (Black Hills).
JOSEPH DIMMICK—Mendocino, Humboldt and Del Norte counties.

To Mining Secretaries.

An amendment to Section 336 of the California Code, taking effect July 1st, 1877, provides that in addition to the regular publication, daily or weekly, of the assessment and sale notices as heretofore,

PERSONAL NOTICE

Must be served as provided in the following quotation from the law:

"The notices must be personally served upon each stockholder, or in lieu of personal service, must be sent, through the mail, addressed to each stockholder at his place of residence, if known, and if not known, at the place where the principal office of the Corporation is situated."

The above refers to the ASSESSMENT NOTICE only. Advertisers in the MINING AND SCIENTIFIC PRESS will be furnished with copies of assessment notices printed on slips suitable for serving personal notice under this law at short notice.

DEWEY & CO., Publishers.

Mining and Other Companies.

Booth Gold Mining Company.—Location

of works, Auburn, Placer county, California.
Notice is hereby given that at a meeting of the Board of Directors, held on the thirty-first day of April, 1877, an assessment (No. 2) of five cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, No. 320 California Street, Room No. 5, San Francisco, Cal.
Any stock upon which this assessment shall remain unpaid on the fourth day of June, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the twenty-sixth day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Directors.
GEO. R. SPINNEY, Sec'y.
Office, 320 California St., Room 5, San Francisco, Cal.

California and Arizona Mining Company.—

Location of principal place of business, San Francisco, California. Location of works, Cedar valley, Mohave county, Arizona.
Notice.—There are delinquent upon the following described stock, on account of assessment No. 2, levied on the third (3d) day of April, 1877, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
Edmund Burch.	13	50	\$1 00
Edmund Burch.	15	500	10 00
Edmund Burch.	17	500	1 00
Edmund Burch.	18	4 000	—
Edmund Burch.	19	200	4 00
Edmund Burch.	21	200	4 00
Edmund Burch.	24	100	2 00
Benjamin Flint.	89	4,000	80 00
W H Hall.	41	2,500	50 00
James W Thrift.	43	2,500	50 00

Name.	No. Certificate.	No. Shares.	Amount.
E E Rice.	44	2,500	50 00
T E Jewell, Trustee.	40	50	1 00
Martin Corcoran.	50	1,250	25 00

And, in accordance with law, and an order of the Board of Directors, made on the third (3d) day of April, 1877, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at Room B, No. 507 Montgomery street, on Monday the fourth (4th) day of June, 1877, at the hour of two (2) o'clock, P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

T. E. JEWELL, Secretary.

Office, 507 Montgomery Street, San Francisco.

Consolidated Bonanza Silver Mining Co.—

Principal place of business, San Francisco, California. Location of works in Eagle and Washoe Valley Mining District, Ormsby county, State of Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 19th day of April, A. D. 1877, an assessment, No. 1, of 10 cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary at the office of the company, No. 19 First Street, San Francisco, California.
Any stock upon which this assessment shall remain unpaid on Tuesday the 26th day of May, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the 19th day of June, to pay the delinquent assessment together with costs of advertising and expenses of sale. By order of the Board of Directors.
W. M. MARTIN, Secretary.
Office No. 19 First Street, San Francisco, Cal.

Dolores Consolidated Mining Company.—

Location of principal place of business, San Francisco, California. Location of works, Dolores Mining District, Esmeralda county, Nevada.

Notice.—There are delinquent upon the following described stock, on account of assessment (No. 1) levied on the seventeenth day of February, 1877, the several amounts set opposite the names of the respective shareholders, as follows:

Name.	No. Certificate.	No. Shares.	Amount.
Blasdel, H. G., Trustee.	16	10,000	\$1,000 00
Blasdel, H. G., Trustee.	17	5,000	500 00
Blasdel, H. G., Trustee.	18	5,000	500 00
Blasdel, H. G., Trustee.	19	5,000	500 00
Drexler, L. P. & Co., Trustee.	8	25,000	2,500 00
J. D. Trustee.	7	10,000	1,000 00
Kelso, J. R., Trustee.	9	10,000	1,000 00
Talbot, W. C.	3	100	10 00

And in accordance with law and an order of the Board of Directors, made on the seventeenth day of February, 1877, so many shares of each parcel of such stock as may be necessary, will be sold at public auction at the office of said company, on Monday, the sixteenth day of April, 1877, at the hour of two o'clock, P. M. of said day, to pay said delinquent assessments thereon, together with costs of advertising and expenses of sale.

J. W. CLARK, Secretary.

Office, 418 California street, San Francisco, California.

POSTPONEMENT.—The sale of the above described certificates of stock is postponed from the 16th day of April, 1877, to the 16th day of May, 1877, and will then be held at the same hour and place named above. By order of the Board of Directors.
J. W. CLARK, Sec'y.

POSTPONEMENT.—The sale of the above described certificates of stock is postponed from the 16th day of May, 1877, to the 15th day of June, 1877, and will then be held at the same hour and place named above. By order of the Board of Directors.
J. W. CLARK, Sec'y.
May 11th, 1877.

Empire Mining Company.—Location of

principal place of business, San Francisco, California. Location of works, War Eagle Mountain, Owyhee County, Idaho Territory.

Notice is hereby given that at a meeting of the Board of Directors, held on the twenty-sixth day of April, 1877, an assessment, No. 13, of \$1 (one dollar) per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary at the office of the company, No. 330 First Street, Room No. 5, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the thirtieth day of May, 1877, will be delinquent and advertised for sale at public auction; and unless payment is made before, will be sold on Tuesday, the twenty-sixth day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.
W. M. McCLINTOCK, Sec'y.
Office, 330 First Street, Room No. 5, San Francisco, Cal.

Mariposa Land and Mining Company of

California.—Location of principal place of business, San Francisco, California. Location of works, Mariposa County, California.

Notice.—There is delinquent upon the following described stock, on account of assessment, No. 10, levied on the twenty-eighth day of March, 1877, the several amounts set opposite the names of the respective shareholders, as follows:

COMMON STOCK.

Iron and Machine Works.

PACIFIC ROLLING MILL COMPANY,

SAN FRANCISCO, CAL.

Established for the Manufacture of
RAILROAD AND OTHER IRON
—AND—
Every Variety of Shafting,
Embracing ALL SIZES of
Steamboat Shafts, Cranks, Piston and Con-
necting Rods, Car and Locomotive
Axles and Frames,

—ALSO—
Hammered Iron of Every Description and Size.
Orders addressed to PACIFIC ROLLING MILL
COMPANY, P. O. Box 2032, San Francisco, Cal., will re-
ceive prompt attention. OFFICE: 16 First Street.
The highest price paid for Scrap Iron.

THE RISDON
Iron and Locomotive Works,
INCORPORATED. APRIL 30, 1868
CAPITAL \$1,000,000.

LOCATION OF WORKS:
Corner of Beale and Howard Streets,
SAN FRANCISCO.

Manufacturers of Steam Engines, Quartz and Flour
Mill Machinery, Steam Boilers (Marine, Locomotive and
Stationary), Marine Engines (High and Low Pressure).
All kinds of light and heavy Castings at lowest prices.
Cams and Tappets, with chilled faces, guaranteed 40 per
cent. more durable than ordinary iron.

Directors:
Joseph Moore, Jesse Holladay, C. E. McLane,
Wm. Norris, Wm. H. Taylor, J. B. Haggren,
James D. Walker.

WM. H. TAYLOR, President
JOSEPH MOORE, Vice-President and Superintendent
LEWIS R. MEAD, Secretary

THOS. PENDERGAST. HENRY S. SMITH

ÆTNA IRON WORKS,

MANUFACTURERS OF
IRON CASTINGS
and MACHINERY
OF ALL KINDS.

Fremont Street, Bet. Howard and Folsom
SAN FRANCISCO.

FULTON
FOUNDRY AND IRON WORKS.
HINKLEY & CO.,

Manufacturers of
STEAM ENGINES,
Quartz, Flour and Saw Mills,
Hayes' Improved Steam Pump, Brodie's Im-
proved Crusher, Mining Pumps,
Amalgamators, and all
kinds of Machinery.

N. E. corner of Tehama and Fremont streets, above
Howard, San Francisco.

SHEET IRON PIPE.

Risdon Iron and Locomotive Works
Corner Howard and Beale Streets,

Are prepared to make SHEET IRON AND ASPHALTUM
PIPE, of any size and for any pressure, and contract to
lay the same where wanted, guaranteeing a perfect work-
ing pipe with the least amount of material.

Standard sizes of Railroad Car Wheels, with special pat-
terns for Mining Cars. These small wheels are made of
the best Car Wheel Iron, properly chilled, and can be
fitted up with the improved axle and box—introduced by
this company, and guaranteed to outlast any other wheels
made in this State.

All kinds of Machinery made and repaired.
JOSEPH MOORE, Superintendent.

SACRAMENTO BOILER WORKS,

37 Fremont St., cor. Mission, S. F.

HALL & KELSHAW,

PRACTICAL BOILER MAKERS,
Marine, Stationary and Portable Boilers, Smoke Stacks,
Hydraulic Pipe, Oil or Water Tanks, Ore and
Water Buckets, Gasometers, Girders, Bridges
and Iron Ship Building.

ALL KINDS OF SHEET IRON WORK.
Repairing promptly attended to at the
lowest possible terms.

PACIFIC IRON WORKS,

First and Fremont Streets, between Mission and Howard, San Francisco, Cal.,
RANKIN, BRAYTON & CO.,

MANUFACTURERS OF

ENGINES, BOILERS, MARINE AND STATIONARY. PUMPING, HOISTING AND MINING MACHINERY,
INCLUDING BATTERIES, AMALGAMATING PANS AND SETTLERS, CONCENTRATORS, ORE FEEDERS,
CRUSHING ROLLS AND ROCK BREAKERS. ALSO, WATER JACKET SMELTING FURNACES,
FOR REDUCING LEAD, SILVER AND COPPER ORES, QUICKSILVER FURNACES,
RETORTS AND CONDENSERS, ROASTING AND CHLORIDIZING FURNACES,
SUGAR MILL MACHINERY, WATER WHEELS, ETC., ALL OF THE

THE O'HARRA CHLORIDIZING FURNACE

Guaranteed to Chloridize from 85 to 95 per cent. of any
gold or silver ores that are not more profitable for smelt-
ing. Will also desulphurize ores and put them in proper
shape for working in cupola furnaces.

Cost of Roasting and Chloridizing by this
Process:

Two cords of wood at \$6.....	\$12.00
Two firemen at \$4.....	8.00
1,500 lbs of salt at 10c.....	22.50
Wear of shoes and power.....	1.50
Cost for 15 tons.....	\$44.00
Cost for one ton.....	2.93 1/3

In a furnace of three or four times this capacity the
cost is decreased by 20 per cent.

The furnace is now working successfully at the Pog Con-
solidated Co.'s mines, in the Peavine District. For
further information, apply to

\$1,000 Challenge Ore Feeder

AWARDED FIRST PREMIUM

At the Tenth Industrial Fair of the Mechanics' Institute.

It may be considered as now fully demonstrated, by careful and long-continued experimentation, that the plan upon which a perfect ore feeder must be constructed is that of the carrier, and not that of the shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply dropped. Spasmodic or jerky contrivances will not answer the purpose.

REFERENCES.

A letter received from the Julian Mill, Newcastle, says of the Carrier Feeder: "It is the most perfect Feeder we have ever seen; don't see how any mill can do without them." A letter from Mr. C. C. Belding, of Amador County, speaks in the highest terms of them. Two of the machines were shipped to the Bunker Hill Mill, also Gover Mill, Amador County. Mr. Stevenson, of Boston Mill, Gold Hill, Nevada, says they are the best Feeder he has ever seen. Soulsby Mill, Tuolumne County. California Company, Nevada City. Omaha Gold Mining Company, Grass Valley. St. Patrick Mill, Placer County.

\$1,000 CHALLENGE.

Backward in Coming Forward.

C. P. Stanford Fails to Come to Time on the Challenge of \$1,000 to Test the Merits of His Ore Feeder as Against Mine. The Challenge is Still Open to Him or any one else. GENTLEMEN, Put up or Shut up.

A letter has been received from the Crescent mine, Plumas County, in which it states that the Tulloch is a failure as against the \$1,000 Challenge Feeder of Hendy's.

We warrant the machines to give perfect satisfaction, and to be a better and more durable Feeder than any other in the market, and will sell them as cheap as any other of its class.

PICKERING ENGINE GOVERNOR.

VALLEJO FOUNDRY, October 17th, 1876.

Messrs. NEYLAN & YOUNG, San Francisco,

Agents for "PICKERING GOVERNORS."

Gentle:—The 10 two-inch Improved Speed Adjusting Governors I bought of you this year for my patent Straw Burning Threshing Engines give splendid satisfaction. They far surpass for regularity of speed any Governor that I have ever seen, and I have seen all the best kinds; I have seen the main belt fly off the pulley several times this season while threshing, and the engineer did not discover it, so perfectly was the speed maintained, until he was told of it; this I consider something wonderful; I consider the Governor absolutely perfect, so far as speed is concerned. I bought and put on to one of my engines a Shive Governor, to see which was the best, and after one season's trial I have no hesitation in saying they are far superior to any other Governor that I have seen or used. I wish you would send me the lowest price that you can furnish 25 Governors for next season's engines. Yours respectfully, J. L. HEALD.

The only Governor that has received awards at each of the International Exhibitions. American Institute Fair, New York, 1865, Two Medals; Mechanics' Institute Fair, Baltimore, 1865, Silver Medal; American Institute Fair, New York, 1869, Two Medals; International Exposition, Paris, 1870, One Bronze and Two Special Medals; International Exposition, Vienna, 1873, Medal of Progress and Decoration; International Exhibition, Philadelphia, 1876, Medal and Diploma.

TOLLES IMPROVED CONCENTRATING TABLES.

Improved Concentrating Tables.

The illustration on this page represents an improvement in concentrating tables for ores recently patented through the Mining and Scientific Press Patent Agency, by J. U. Tolles, of Virginia City, Nevada, who has been using the apparatus very successfully in several places. In the engraving, A represents a flat inclined table provided with a surfacing of cloth or other suitable material of any kind, and with the ledges b, to prevent the material from passing over the ends. B represents a peculiarly constructed feed box extending along the upper edge of the table and provided in its front side with a row of discharge openings, c, of the form shown, each narrowing down to its lower end and of such a size as the nature of the material requires. C represents a receiving box or trough, extending along below the lower edge of the table. D represents a leaf or board hinged to the rear side of the trough or box C, in such a manner that it may be turned under the edge of the table to conduct the valuable material therefrom into the box, the refuse passing over the edge of the table and discharged upon the ground, or into the box in the rear of the box C. E represents a rotating tube or pipe suspended lengthwise above the upper edge of the table by endless belts d, passing over pulleys e, supported in the rigid frame f, or by brackets fastened to the frame and extending out the proper distance over the table, the tube resting and rotating upon them as shown in Fig. 2. The tube is provided from end to end with a row of perforations, and with a hand lever, h, at one end, and is connected by a hose i, to a tank, pump or reservoir, delivering water at a pressure of from eight to 12 feet of head, as the nature of the case requires.

In operating the machine the feed box is narrowed to about one inch at its farther end, or has a strip of board set edgewise in the bottom, and running obliquely across the same from the rear to the front side, causing the material to gradually be brought to the front and discharged through the feed holes c, upon the table, thereby insuring an even distribution and steady flow of the material to be treated; a steady and copious supply of water is maintained in the box, and the ores, sands or tailings introduced therein. The water escaping through the openings, c, flows down in a thin light stream over the face of the table. The mineral particles are deposited upon and retained by cloth or other surfacing material on the face or bed of the table, while the light refuse matter is carried over the lower edge and discharged outside of the box C. After the collection of a suitable amount of metal upon the

table, the supply of water, etc., to the feed box is stopped by the gate and turned upon the other table. Clear water is now supplied to the first pipe, E, and allowed to run down over the table, for a moment, washing off the remaining refuse sands, and at the proper time the hinged leaf D, is drawn (by the rod) under the edge of the table, the pipe being rotated or turned and the water thrown through the perforations upon the table in a row of fine jets, forming an almost continuous sheet or film. By means of the lever h, (which should be fastened on the pipe at right angles to the line of perforations), the tube is turned and the sheet of water swept over the table from the top to the bottom so as to drive all adhering particles therefrom and wash them down into the box C. After this operation the jets are stopped from the tube, the leaf

The object in arranging the perforated pipe so that it can rotate is to permit a gradual change in the direction of the jets, so that their point of impact upon the table can be advanced from its upper to its lower edge, and thereby every portion of the surface subjected in turn to the direct impact of the jets, in order to effectually loosen and drive forward the particles therefrom.

The flow of water can be regulated by the valves operated by the cords. The gate shown in the feed trough, G, will throw the water into either feed trough as desired.

thrown back, and the gate shipped to the other feed box, the feed water coming back on the first table, the operation being repeated as often as it is seen the tables are changed with the sulphurets or other valuable metals.

By employing the proper kind of cloth, grooves, riffles, or copper plating, or all of them combined, and giving the tables the proper grade, and properly regulating the flow of water, the inventor finds that he can effect a very rapid and thorough separation without agitating the table, and without power of any kind except the manual labor requisite to change the feed from one table to another, and washing them off by means of the water used in the pipes; he also finds by the employment of the fixed table he can separate particles which cannot be retained in machines which vibrate. By use of the feed openings, c, of the form shown, the discharge of the sand, ore or other fine material is rendered very steady and gradual, as it will be carried through the narrower portion of the openings, while the lighter water will pass over the same through the upper large end of the openings, taking up the material very gradually and distributing it very evenly upon the table. It is obvious that the rotating tube may be substituted in any other manner, and that it may be connected in any suitable manner with the source of the water.

The plugs in the ends of the pipes, E, are for the purpose of freeing them of any obstructions.

Fig. 3 represents the most convenient form of erecting the tank or reservoir which supplies the tubes with water, it usually being placed directly overhead with water shed underneath.

Mr. Tolles with this apparatus does not profess to do what many others claim to do, but he is running many of them where everything else has failed. He has been running several of these tables on the Comstock for nearly two years and is now building more. By using the proper kind of sizing apparatus in connection with the tables, the inventor is doing some close work with them at a nominal expense of constructing, running and keeping in order. He states that any person using anything of like nature, or any portion of the same for like purposes, without first obtaining license or instructions, will be prosecuted for damages for such use. Persons at a distance can build and run them by first obtaining license and instructions from the inventor, John U. Tolles, at Eureka, Humboldt county, California, or W. S. Tolles, his authorized agent at Virginia, Nevada.

DOUBLE SHEET EDITION, 24 Pages

Mechanics' Liens on Mines and Mills.

A case has just been decided by the Supreme Court of the United States on the subject of mechanics' liens which is of great interest to mechanics as well as to owners of mining property. The decision was on an appeal from the Supreme Court of Montana Territory, Andrew J. Davis, appellant, vs. Harvey Alvord, et al. Work was done by the plaintiff under a contract with the defendant, made August 1st, 1869, on two distinct parcels of property in Montana Territory; one a quartz mill and the other a quartz mine, separated a considerable distance from each other. The work on the mill was completed in the fall of 1869 or in the summer of 1870. Nothing was done afterwards except to make occasional repairs as they were needed. The work on the mine was done in 1870, but it was not shown when the work was commenced. In June, 1871, upon an accounting between the plaintiff and the defendant, there was found due to plaintiff a large sum, which the parties agreed should be a lien upon the mill and mine in equal proportions. Notices claiming a lien upon each for the amount as thus apportioned were accordingly filed in the recorder's office.

The Court decided that a suit to recover judgment for labor performed by the plaintiff upon a quartz mill and mine in Montana, to enforce a mechanics' and laborers' lien on the defendant's interest in the premises for the payment of a judgment, is a suit in equity, requiring specific directions for the sale of the property, such as are usually given upon the foreclosure of mortgages and sale of mortgaged premises. The fact that, according to the modes of procedure adopted in the Territory, a personal judgment for the amount found due is usually rendered in such cases, with directions that, if the same be not satisfied out of other property of the debtor, the property upon which the lien is adjudged to exist shall be sold, and the proceeds applied to its payment, does not change the character of the suit from one of equitable cognizance, and convert it into an action of law.

Mechanics and laborers asserting a lien upon real property for their work, and claiming priority over mortgages and others, who have acquired interests in the property, must furnish strict proof of all that is essential to the creation of the lien; and that requires them to prove when the work was commenced, the character of the work, and when it was completed.

It was held by the Court, 1st. That a lien did not arise from the contract of apportionment or from the special contract, referred to above, under which the work was done, but for the work itself which was performed upon the property. 2d. That the work being done on different parcels of the property, the lien claimed on one was to be considered separately from the lien claimed on the other. 3d. That the notice, so far as the mill was concerned, was filed too late, the statute requiring the notice to be filed within 60 days after the completion of the work; and that the occasional repairs subsequently made could not be added to the work done months before, so as to render the whole work one continued performance for which a single lien could be claimed within 60 days after the last repairs. 4th. That it not appearing when the work upon the mine was commenced in 1870, it will not be presumed that it was commenced before the mortgage of the defendant was executed and recorded in September of that year, so as to give to the lien for the work priority over the mortgage.

The decree of the Court was that whilst the statute giving liens to mechanics and laborers for their work and labor is to be liberally construed so as to afford the security intended, it cannot be too strongly impressed upon them, that they must not only bring themselves by their notices, as was done in this case, clearly within the provisions of the statute, but they must be prepared, if the priority of their lien be disputed, to show a compliance with those provisions and fix with certainty the commencement and completion of their work; in which particular the proof here is wanting.

The decree of the District Court of the Territory, therefore, has to be modified so as to give the mortgages held by the defendant, Davis, a priority over the lien of the plaintiff in the distribution of the proceeds arising upon the sale of the interest of the defendant, Hendrie; and the cause was remanded to the Supreme

Court.

THE NEW MINES. — Ralph Woodward has received some more samples of ore from the recently discovered mines near the Battle Mountain road, about 30 miles northwest of Austin. The Reveille says the ore shown from these mines is solid, argentiferous galena. The ledge from which it was taken is named the Eureka, its width is short nine feet, and the discoveries have sunk on it to a depth of thirty feet. The mines are within the limits of Reese River dis-

River Mining.

As there is very little snow in the mountains, there being but little rain last winter, a good many miners find it a good opportunity to try their hands at old-fashioned river mining again. In the early days this "summer mining" was done in many places by putting in wing-dams, pumps, wheels, etc., by which the miners could sink down to the natural bed of the river and get at the rich deposits on the bottom. The hydraulic operations which have been carried on for so long have had the effect, however, of filling up the beds of many of the rivers with heavy, deep deposits of debris, gravel, etc., and of late years this style of mining has been considered impracticable. To get over the difficulty some companies are at work sinking shafts on the banks, with the intention of running drifts out under the beds, and working that way. The low stage of the water, however, this summer has induced many to go to work in the old-fashioned way, and lots of them are hard at it now. Feather river is being flumed and wing-dammed from high up in the mountains down as far as it will pay. The Butte Record says there are probably three times as many companies at work on it to-day than ever before at one time. We were informed by a miner from up country this week, that the Stanislaus river is also being worked in the same way in places. The Bear river is also being mined in this style. The Grass Valley Union gives an account of the undertaking of Webster & Harrison, of Colfax, who have commenced operations this season by putting in a dam across the mouth of Greenhorn creek, at its junction with Bear river, and digging a canal from thence for some distance down the river, which will supply water to run the wheels for pumping out a claim which they have located below the junction. They are also building a long wing-dam on their ground to throw the water of Bear river to the east bank, by which means they will keep the surface of the claim dry. There is no probability that the water will increase in Bear river this season, as there is but little snow in the mountains, and they have the prospect of a long season's work before them. At the point at which they will work the river has filled up with tailings to the depth of twenty-five or thirty feet, and heavy stripping will have to be done to reach the bottom. It requires pluck and faith to go into such an enterprise, and the projectors certainly deserve a rich reward.

MINE MODEL.—A device for showing the character and interior of mines has been placed in the United States Circuit Court-room, in readiness for the trial of the suit of the Richmond mining company of Nevada vs. the Eureka mining company, to determine disputed boundary rights, which is expected to come on almost immediately after the court reopens for business. The model is made altogether of glass, and represents the principal tunnels, shafts, inclines, ore chambers, etc., of the Richmond and adjacent mines in Eureka mining district, as they would appear if cut by horizontal and vertical planes, passing through Ruby hill at points indicated by the glass plates upon a scale of 40 feet to an inch. The size of the model is six feet by four feet, and three feet in height to the apex of the mountain. There are altogether 40 large plates of glass besides the uprights, and the contour of the surface is the exact shape of the ground. The lodes and veins of ore are boldly shown, painted in red, and the drifts are traced in black ink. Every detail is distinctly marked, so that it is easy to gain clear knowledge of all particulars. N. Westcoat, civil and mining engineer of Nevada, made the surveys and he, assisted by C. T. Healey, constructed the model. This device is similar to the one showing a model of the New Almaden mine, exhibited at the Mechanics' Institute fair a few years ago. That, however, was on a smaller scale, although made in the same way.

On the 22d inst. the Hite mine shipped bullion valued at \$11,100, making the total shipment for May amount to \$22,318. This mine, so long a private institution, is now worked by a corporation.

FIG. 1. PERSPECTIVE VIEW OF THE BALL STEAM STAMP. (See Page 345.)

Court of Montana, with directions to modify the decree in that respect.

PATENTS TO MINES.—The following patents have been issued by the Department of the Interior: Edith company, of California, for the Maud, Golden Gate, St. George and Eagle lodes; also to the Allison Ranch mining company, for the lode of same name; to E. A. Wall, Bullion No. 3 lode, Utah; to Adams Hill Consolidated mining company, the Wide West lode, Eureka, Nev.

MEMORIAL day was observed in a becoming manner in this city.

strict, said district having been extended to take them in, so that they might be governed by its old-established laws.

BULLION SHIPMENTS.—Since our last issue shipments of bullion from prominent mines have been as follows: Grand Prize, May 25th, \$6,800; Modoc, 23d, \$11,341.48; total to date, \$77,493.77. Northern Belle, 24th, \$12,216.51; Standard, 24th, \$9,479.75; California, 26th, \$321,190.34; total to date, \$1,035,579.81. Con. Virginia, 26th, \$227,466.97; total to date, \$462,390.63. Tybo, 22d, \$8,735.07; total to date, \$53,690.83.

CORRESPONDENCE.

A Sketch of the Mining in Plumas Co.

Quartz is at present attracting unusual attention. The center of the interest is at Greenville, in the upper part of the county, 25 miles above Quincy. The immediate cause of the excitement may be attributed to some reported late rich discoveries at the head of Soda creek, about 10 miles from Greenville. The ledge is represented to crop out boldly for 600 feet, showing much gold to the naked eye in the surface quartz. One claim,

The Washington, Although a mere surface prospect, changed hands soon after its discovery at \$20,000. Many other locations have been made, believed, as a matter of course, by those most interested, as even more promising. A good wagon road is in active process of construction, connecting the mines with Greenville, and prospecting may be said to be the general order of the day.

The interest has, perhaps, been deepened by the comparatively recent developments on Wolf creek, which has been favored by the introduction of San Francisco capital. Better still, the investments have been judiciously made and skillfully managed, the operations thus far proving successful and profitable. As a consequence the contagion prevails to some extent at Taylorville, Crescent mills, and other places in this portion of the county, spreading as far south as Quincy. In addition to this there are a number of drift claims just on the eve of giving forth their treasures, while some new gravel deposits are about being opened up, or companies organizing for the purpose, all of which seems to give just at this time, an exceedingly promising outlook for the mining interests of this county. The oldest citizens say, in fact, that the prospects were never brighter or better.

The New York Mine, One mile south of Greenville, the property of Messrs. Whitlock & Treleven, is one of late discoveries here, and at present vigorously worked. The general course of the vein is north and south, average width three and a half feet for the distance of 225 feet, and explored by several tunnels, the lowest tapping it at the depth of 300 feet from the surface. Formation, porphyritic granite.

The rock taken from tunnels so run has been submitted to three different working tests; the first paying \$12 per ton, the second \$15.75, and the third \$28. A good 10-stamp mill, run by water power, has just been finished and is now in complete running order, into which the quartz is dumped directly from the mouth of the lower tunnel. As any quantity of ore can be extracted to keep the mill supplied, there can be no question as to the result.

The Indian Valley Mine, In the same vicinity, owned by Mr. J. N. Blood, has been developed by shaft to the depth of 650 feet, making some 1,300 feet from foot of same to the apex of the hill through which the ledge runs. It lies between the syenite and the porphyry, and averages about 12 feet in width, the quartz milling \$15 per ton. It has a good record, and work upon it is expected to be resumed within a few days.

The Gold Stripe G. M. Co., Mr. H. C. Bidwell, Superintendent, is a San Francisco incorporation, with mine and mills at Wolfe creek, six miles from Greenville. The country rock is porphyry and talcose slate, the richest pay being found in the decomposed gangue which forms a large proportion of the quartz. The width of vein in the main working tunnel is 33 feet—the whole of quartz being extracted and milled. The company commenced active operations less than a year ago, since which four different levels have been run, the main working tunnel after it struck the ledge, following it through pay ore the distance of 170 feet, and attaining a depth from surface of 146 feet. A shaft following the hanging wall the same distance was run through a solid mass of quartz, and a cross-cut on the vein 70 feet west of shaft was run north to foot wall, the opening also developing a fine body of quartz. Many other details promptly furnished by Mr. I. Prowattin, Assistant Superintendent at the mine, are necessarily omitted. This much, however, may be added. A new level is now being run, which is designed for the future main working tunnel, which will tap the vein at a further depth of 180 feet, and a fine tramway from mine to mill has just been completed, which will greatly facilitate the operations. The company are blessed with milling facilities, having a small water mill of eight stamps, a 24-stamp mill and another of 32 stamps each run by steam, and contemplate the erecting of a 16-stamp mill in addition to those in use. The crushing and amalgamating department is confided to the charge of Mr. Geo. Standart, and it is scarcely necessary to add that the work is well performed, and that the rock is paying the company handsomely.

Adjoining this valuable property on the same ledge is

The Great Western.

It is, as might be expected, very similar in

character. It is being thoroughly prospected by four tunnels, and the results are so encouraging as to shortly warrant the erection of a 40-stamp mill, which the owners are said to have in contemplation.

The Clear Creek, the third extension, and some half a dozen other claims in the neighborhood, are represented to show fine prospects. Wood and water is found in great abundance. This camp is at present among the liveliest in the State, and gives promise of even a far brighter and more prosperous future.

The Crescent Mill and Mining Co's Claim, Six miles from Greenville, on the road to Quincy, has been worked more or less for the past 14 years, having added in that time an immense amount to the bullion product of the State. It came into the hands of the present company two years ago, since which it is represented to have paid a considerable sum over and above expenses for working and developing. It is looked upon as a very valuable property when once properly opened, and its future prospects thought to be flattering. The company have commenced to sink a new shaft 600 feet east of the old works, giving them a more central location, and better ground for attaining a greater depth, to which point the hoisting works will be removed.

They have three veins—the Horse-shoe, eight feet wide, with four dollar rock; the Pet, on which the new shaft is located, two feet and paying \$15, and the Crescent or main vein, which averages two feet in width and pays about eight dollars per ton, the whole rock for April having averaged \$12. The formation is granite and slate. The mines and large 32-stamp mill adjacent are under the superintendence of Mr. J. F. Jewell. He gracefully submitted to an interviewing and granted the desired information without a resort to the force pump. The mine is probably not on the boards.

The Green Mountain Mining Company.

This mine has been worked for 12 years. The lowest level, the seat of present workings, is at a depth of 700 feet from surface. By far the larger portion of the vein above this level, from which the company are now stopping, remains to be worked. The vein is known to be exceedingly large, but its entire length and breadth has not been fully explored, and while the grade of the ore is by no means first-class, it is found in such large bodies and so easily extracted and crushed as to place it among the best paying mines of the country.

Such is its reputation at least in the vicinity. The mill consists of 32 stamps, run by a hurdy-gurdy wheel—the water being brought from Round valley by a ditch seven miles long, belonging to the company.

The quartz is conveyed from the mine to mill by an incline tramway 1,600 feet in length, the mill being so situated that 350 feet of backs could be obtained by running a tunnel on the level of the mill. In short, the mine is very admirably situated, and everything around it most conveniently arranged for successful working. Mr. E. Green, President of company; Mr. C. G. Rogers, Superintendent of mine.

The Kittle and the Caledonia, first and second extensions on this ledge, and owned principally by members of the Green Mountain company, will be eventually worked through the same tunnel. The original location is known to be 60 feet from wall to wall, and to have three distinct veins within them—facts forgotten in their order—and the more recent locations doubtless possess the same characteristics, they may be looked upon as almost equally valuable. Two miles north of Quincy is

The Belle G. M. Co.,

Mr. R. Z. Belle, Superintendent. The mine has been prospected on its line the distance of 600 feet by open cut and tunnel, from a point on the vein where the shaft is located. The tunnel reaches a depth of 150 feet from the surface. The shaft is 30 feet below the water level and 50 feet lower on the vein than the tunnel. From the developments the vein is found to be from 40 to 50 feet in width, the gangue made up principally of partially decomposed quartz and talcose slate, and the whole carrying gold in sufficient quantities to justify the company in erecting a mill. They begin with 10 stamps, including in the plan, arrangements for 10 additional stamps when required.

Besides many satisfactory tests from the ledge, not less than \$750,000 have been washed from Betsy gulch, immediately below where the gold has been deposited by the wearing and washing away of the decomposed ledge matter for ages past. The claim is situated in the slate range, but in near contact on one side with the granite.

The O'Neil Ledge,

In the same vicinity, is four feet in width, prospects well in free gold; the quartz also much decomposed and thought to work as high as \$15 per ton.

From three to four locations have been made on this lode—all represented as promising prospects—and work has been commenced in earnest. The owners evidently mean business.

No details were obtained in regard to

The Plumas Eureka Mine

In the southern part of the county, as it is understood to be the property of an English company who prefer to have little publicity given to their affairs. It is well-known, however, to be one of the best paying quartz mines of the State. The company have a large 48-stamp mill, a Bruckner roasting furnace, 22 concentrators, two pans and two settlers, all admirably arranged for successful working, and

give employment about the mine and mill to not less than 150 men.

Drift and Hydraulic Mining.

Your readers have been so well posted in the "Mining Summary" columns of the Press, by extracts from the *Plumas National*, in regard to the gravel deposits of the county, but little remains to be said—and even that little is written under the risk of much repetition.

Would that all the local papers were as careful in their statements. It would greatly enhance the value of this department of the MINING AND SCIENTIFIC PRESS, and be a great benefit (instead of an injury, as often, from the reaction from overdrawn pictures) to the localities they represent. It might be well to preach a short sermon, say once a quarter, to your exchanges on the subject. Their intentions are all right. Their opportunities for gathering accurate information are certainly far superior to those of a traveling correspondent, while the temptation to give colored and flattering reports cannot be greater. Lay it on a little mild, something after the schoolboy's "infinite stretch of elongated veracity" mode of expressing it, and rest assured it will result in a great blessing to editors, readers, individual communities and to the grand public whereof we all form a part.

A New Enterprise.

The Grizzly Ridge mining company has been just incorporated, for the purpose of prospecting a portion of hitherto undeveloped ground nine miles southwest from Quincy.

It is thought to be on the great blue lead, and is fine drifting ground. It is supposed to be quite extensive, and sufficient pay has been found in the gravel to raise expectations in that direction to a high pitch.

Munford's Hill Gravel Deposit,

Ten miles west of Quincy, is about 20 acres in extent and from 30 to 50 feet deep, with a quartz ledge underlying.

The gravel has been rich in coarse gold and pays fair profits yet; say about \$15 per day to the man while water lasts. The quartz ledge, known as the Diadem, underlies the gravel at the bottom of the channel, and is of an average width of 50 feet, with wall rocks of clay and talcose slate. Veinstone mainly of magnesian limestone, much decomposed into a soft red mass, carrying fine free gold, with strata of talcose slate, containing gold-bearing sulphurets. Coarse gold is here found associated with talcose slate. A large portion of the ledge contains from \$2 to \$5 per ton of free gold, while some smaller veins thereon give assays up to \$40. A shaft has been sunk \$100 feet. There is an aqueduct on the ground run by water, used for prospecting. It is the intention of Messrs. Edman & Co., the owners, to work the ledge by hydraulic, when the gravel is washed off.

The Golden Enterprise,

Owned by Mr. Richard Jacks, is a hydraulic claim, situated on Spanish creek, eight miles west of Quincy. The flume is 12 feet wide with partition in the middle, and is set at a grade of one and one-half inches to 12 feet. It has been already extended 720 feet, and a cut also just opened (wide enough to receive the flume) 366 feet in length, which will open up the whole basin above, and what is believed by the owner to be one of the finest gravel deposits in the State. By a resort to a reservoir, if necessary, 800 inches or more of water can be had, the year around, with a pressure of 200 feet or upwards. Chinamen are now working on the ground above the flume and making fair wages, four men in one month having realized by means of ground sluicing as much as \$480. As much money has been required for the undertaking, it is to be hoped that the owner will soon be amply rewarded for the means and time expended.

The Plumas Mining and Water Co.,

Mr. N. Cadwallader, President and Superintendent, have 20 acres on Gopher hill, six miles from Quincy, 160 acres on Bear hill, four miles above Spanish ranch, and about an equal amount of ground at the Mountain house, two miles above. The company are at present working their claim on Gopher hill, using 1,200 inches of water, (pressure 240 feet,) and six Little Giants, with three of them in constant use. The deflector invented by Mr. H. C. Perkins, Superintendent of the North Bloomfield M. Co., was found here, giving excellent satisfaction. The bank is in the neighborhood of 150 feet in height—40 feet of the gravel nearest the bed-rock containing the pay. The yield from the mine within the past three years is not far from \$82,000. Last year two and three-quarters acres were worked, producing \$30,000, leaving a margin for profits of \$16,000. The ground is expected to yield the present season in like ratio, as the amount of \$7,900 already cleaned up is about at that rate.

Zinc Amalgam

Is used here in lower end of the sluices and has been found very effective in saving the gold at the same time, with less loss in quicksilver. Owing to its peculiar affinity for gold, it seems to have the effect of thoroughly cleansing it of rust. The fact, although not wholly unknown, was accidentally discovered by the company from washing off a portion of their ground on which an old blacksmith shop had stood, and around which lead, zinc, solder and other refuse had accumulated. The same having lain over all winter in the lower end of the sluice was cleaned up in the spring. The quicksilver having eaten up the solder and other refuse and heavily charged with the contents, was used

during the following season. When it was continually strained a certain amount remained in the cloth. Fifteen pounds were obtained during the season that yielded, after retorting and turning into a bar, \$600. Like all wide-awake miners they immediately turned the accident to good account, and have been using the zinc amalgam greatly to their advantage, as they fully believe, ever since.

Messrs. Conly & Gowell, at Laporte, have worked successfully on rich ground, and expect a good clean-up for the season. The Dutch company's claim at the same place, recently purchased by a San Francisco company has had a large amount of ground worked with good results. The new company intend to bring in the South Fork of Feather river by a tunnel through the mountain one and one-half miles in length, giving them, it is said, one of the finest water rights in the northern part of the State. They are represented to have over 3,000 acres of good virgin ground and the enterprise is spoken of as one of the grandest that has for many years been undertaken.

Favorable news may be looked for the ensuing season from Nelson Point and Sawpit Flat, as some of the claims are expected soon to be in readiness for advantageous working.

A. C. K.

Notes from New York.

EDITORS PRESS:—New York harbor, including, of course, the "North," "East" and Harlem rivers, is full of interest, even to the casual observer, and I find, on looking over my note book, that a few trips across one of the "long ferries" have given me matter enough to fill my column, and more, too, perhaps. For the last two months, I judge that there have been more vessels lying at the docks between the Battery and Grand street than have been seen before for a year or two. Vessels discharging, English and coast steamers discharging, vessels in the floating docks, and others near by, for repairs, made the river seem very lively, and during the early part of the winter there seemed to be scarcely a dock empty for a mile above the Battery, on the New York side. Early in March, I saw an English freight steamer, which came in by way of

Long Island Sound and Hell Gate.

So far as I can learn, this is the first and only boat that has taken the new route. In spite of all the talk, Long Island sound cannot be made popular with the captains and owners of ocean steamers, and until it is, the new channel through Hell Gate will not be much used, except by the coasting trade. Speaking of Hell Gate brings to mind one of the results of the increased water way, and that is a seeming increase in the velocity and duration of the tides in the East river. I have no figures at hand, but it seems as though the boats upon the Roosevelt street ferry are much longer in making their trips, when the tide is against them, than formerly. The boats, in leaving and entering the slips, also seem to be more affected by the currents, so our gain has not been an unmixed good. As Hell Gate was what is called the controlling action of the river, any enlargement there will be followed by a decided increase in the volume and velocity of the water flowing in the river. The increase will probably go on until all the operations for improving the river are finished.

One of the prominent features of

New York Harbor in the Summer,

Is the immense number of excursions in all directions. The steamers used for this purpose range in size all the way from a tug-boat up to river steamers like the *Plymouth Rock*, capable of carrying some thousands. Many of these are old boats, but of late years the business has become so profitable that new boats are built for this especial purpose. The last and most unfortunate of these was the *Rockaway*, of which the papers have given such full accounts. She was built in Norfolk, Va., and was intended for an excursion boat between this city and Rockaway. She was wrecked, however, on her way to this city, having broken up at sea during a gale, and went ashore at Cape May. The owner, nothing daunted, means to have a boat ready by the Fourth of July, and I hear that the keel has been laid in one of the Greenpoint shipyards. As the hull only was lost and the machinery is still available, the boat that was lost not having received it, being a mere hull, the feat will not be so difficult. These excursion boats do not need state-rooms and the like fittings, so that the amount of labor is much smaller than would be required on passenger boats on regular lines. The boat, I believe, is to carry something like 2,000 people, and if that is what is permitted by law, it is tolerably safe to double it to get at the actual number carried. At the Poillons yard, in Brooklyn, they have recently launched a

River Steamer,

Which is about 150 feet on the keel. She is also intended for harbor work, and is, I believe, receiving her machinery. The *Massachusetts* is the last great thing in the steamboat line. Last week she was on the sectional dock in the East river. Taken altogether she looks the largest

MECHANICAL PROGRESS.

Cold-Chisels.

The most indispensable tools, says the *Manufacturer and Builder*, for the practical mechanic are the cold-chisel, hammer and file, and yet very few, even among our best mechanics, know how to use properly the commonest of mechanical implements. There are possibly some, who, after years of practice, may be able to chip a plain surface so smooth as to require but little filing, but such men are the exception and not the general rule.

The first and most important requisite is to have tools properly made and of the right shade and temper, and it is essential that a good workman should know when they answer these requirements. To make a good cold-chisel demands a knowledge, not only of the material of which it should be made, but also of the use to which it is to be put. Blacksmiths are usually not accustomed to dressing tools, and are apt to heat the steel too hot; besides they are generally in two great a hurry to make a good job. For this reason most mechanics prefer to make their own tools.

For a first-class chisel the steel should be heated to a bright cherry-red—no hotter—which is best done in a charcoal fire, though other fuel will answer the purpose. If stone coal is used, care must be taken that no fresh coal is placed upon the fire while working the steel, as the sulphur in the coal is liable to injure the metal. The best form of steel for chisels is the hexagon or octagon bar. In drawing out the blade of the tool it is necessary to hammer the steel as much upon one side as the other, to make it as nearly as possible of a uniform density throughout, and to prevent the springing of the blade when it comes to be tempered. Heat the steel often while forging, but never above a cherry-red heat, which temperature should be maintained as uniformly as possible until the tool is brought to the proper shape; it should then be hammered till quite black, to give it toughness and elasticity. To temper the tool, heat it to a dull red, and dip the blade a short distance into clean, moderately cold water; hold it there several seconds until the part immersed is quite cool, then with a stone or piece of brick scour the point tolerably bright and watch the color as it runs down. For chipping, a dark blue, inclining to purple, will usually give the right temper; but as this depends greatly upon the quality of steel, the precise shade can only be determined by actual experiment. When the blade shows just the right color, the tool should be quickly immersed in water and allowed to remain until perfectly cold.

IRON CROSS-TIES.—The substitution of iron for timber in railroad cross-ties is being made a matter of test by the C. P. R. R., as we have noted formerly. The latest device for accomplishing the end is by M. Potel, C. E., advocating the use of a wrought iron cross-tie, semi-elliptical in shape, resting simply on the ballast. The rail is fastened to the cross-tie by a quite novel and most ingenious, although simple, contrivance, called by the inventor the "jawbone chair," or *cousinnet machoire*. This is formed of two portions which hook into one another, and the shape of which is such that they hold the rail as if in a vice. Half of this chair is firmly fastened to the cross-tie by means of a bolt, and preferably on the outside of the track. The other half hooks into the first beneath the cross-tie, and is movable. An ordinary eye-headed bolt entering through the hole of the tie adapts itself to the end of this movable arm, and by its successive tightening compensates for any downward wear of the rail. The laying of a track of this description, it is claimed, presents no difficulties whatever, being rapid and inexpensive, and confined to the tightening or loosening of a bolt. To the above arrangement M. Potel has added another apparently small, but really important, contrivance, which does away with all necessity for differential punching of the cross-ties (or even, if desired, of such longitudinal sleepers), and which resides in the adaptation of a washer of hexagonal shape placed below the bolt head, but which, instead of being pierced by a central orifice, has the bolt placed eccentrically, so that by rotating this plate after loosening the bolt any one of the sides of the hexagon can be brought to bear on the shoulder of the jaw.

JOINTS FOR STEAM PIPES.—M. Dresel, paper manufacturer at Billefeld, informs us that cellulose is well adapted for making steam-tight joints when the pressure does not exceed 10 atmospheres. The material costs but little and has great durability. Under the influence of water it swells and thereby makes the joints still tighter.—*Revue Industrielle*, viii., 136.

PROGRESS OF THE ST. GOTHARD TUNNEL.—The advancement of work on the tunnel of St. Gothard during the week ending March 20th is reported to have been 20,590 m. at the Goeschenen and 21,300 m. at the Airole end, or together 41,890 m., about 5,590 per day.

STEAM ON ENGLISH STREETS.—The English seem inclined to permit the use of steam power on their street railways. Iron says: "The report of the committee on the use of mechanical power on tramways, which was laid on the table of the House of Commons, contains additional information with regard to the rate of speed. Although the committee decline to pledge themselves as to what legislative measures may be required in the future, they are of opinion that the use of mechanical power should be permitted on tramways; and also that any provision or order, granting the necessary powers should contain clauses embodying the regulations of the Board of Trade with regard to the use of mechanical power for such a purpose. That is to say, it would be necessary that the machinery should be concealed or protected from view; that every engine should be as free as possible from noise of machinery or blast, and should not emit smoke, steam, or any noxious and unpleasant vapor; that sufficient brake power should be applied to stop engine and car in their own length when traveling eight miles an hour; that the engineer shall not travel at a greater speed than a rate of eight miles per hour in town and 12 miles in country, and that the Board should have power to license the trial for a period of three months of any particular engine on a tramway which has complied with the orders. The committee finally recommend that any bills or provisional orders introduced this session should, as far as possible, be placed in the same position as if their progress had not been delayed by the appointment of the committee."

PROPOSED WHOLESALE EMIGRATION OF BRITISH IRON WORKERS.—A representative meeting of the iron workers of the United Kingdom has taken place at Manchester, when the question of the notice given by the North of England ironmasters, with the intention of further reducing wages was considered. It was resolved to bring before the employers the fact that at no period have the men received less than eight shillings per ton for puddling, and that that they can barely subsist with the present eight shillings three per ton, when the greatly increased cost of living is considered. If the employers persist in their intention, and the result of the arbitration should be to lower wages, it is determined that a meeting the men should be held for the purpose of considering the desirability of expending the whole of their funds, amounting to £10,000 for the purpose of assisting the iron workers to emigrate to the colonies, and that, to promote this object, communications be opened up with the governments and others desirous of developing the iron trade in the colonies where raw materials and the facilities for the production of iron exist.

REMOVING SCALE FROM FLUES.—C. Graham writes for the *National Car Builder* as follows: I notice a statement of the method of cleaning boiler flues employed by Mr. S. S. Pilsen, loosening the scale by heating the flues in a furnace, after which they are straightened upon an iron rod. I have for the last eight or ten years used a somewhat similar plan and find it to be very effective. Our furnace not being large enough to heat the whole flue at once, we heat only one end at a time. By putting a little waste in the outer end, the fire is prevented from being drawn through it, and the end is kept sufficiently cool for being handled without using tongs. By the time each flue of a set has been heated in this way, the first ones are cool enough to handle again, when the other ends are treated in the same way. We straighten the flues by simply placing them while hot on a plank, and striking them lightly. The scale is taken off by drawing the flues two or three times between a couple of old files fastened in a block in the form of an X. There is, I think, a manifest advantage in cleaning half the flue at a time, as it is more easily handled and not so apt to bend.

HORSE SHOEING.—Travelers in Europe describe two different ways of shoeing horses in Turkey and Russia, which may seem very awkward compared with the simple method of American smiths. In Turkey and Servia the horse's head is held by one man, another holds the leg on his arms, while the third operates on the foot. In Russia the horse is placed in a square cage made of rough planks of wood, and is strapped around the belly with wide leather straps attached to cross-bars of the framework; his head is also tied safely; the foot is fixed to a stake in the ground and held by an assistant while the smith places the shoe on.

NO STRENGTH IN SURPLUS METAL.—The recent paper by Mr. Macdonald showed that there was more than enough of iron employed in the Ashtabula bridge, but that the faulty application of that material was the cause of the disaster. The London *Engineer* arrives at the same conclusion, and thinks that the lesson deserves attention in Great Britain. It says: "The failure of this bridge affords another proof of the fact that surplus material will not necessarily secure the stability of a structure. At the present moment several large iron structures in this country, although perhaps not liable to the same disaster, yet constitute undoubted examples of a similar waste of material. There is plenty of room at home for judicious economy of iron structures, in the proper distribution of the material, and the scientific management of the various parts." The warning conveyed by the disaster should also be regarded in this country by other iron users beside bridge builders.

SCIENTIFIC PROGRESS.

Experiments with Native Iron.

In its sitting of March 12th a paper was received by the Academy des Sciences, Paris, from M. Damour, descriptive of the specimen of native iron found at Santa Catarina, in the Brazils, and analyzed on the spot by Messrs. Guignet and Osorio. This analysis will be found in the number of the *Comptes Rendus* for November 6th of last year. It gave as the composition of the specimen 64% iron and 36% nickel. The metal is a compact mass, having the color and metallic luster peculiar to forged iron. It does not resist the file. Although malleable, it can be broken with a sharp twist. Its fracture shows a fine grain, and exhibits a sort of stratification in certain places. When polished and treated with an acid on one of its surfaces the peculiar appearances known as Weidmanstätten's figures are brought out. Filings of the metal do not oxidize on exposure to the air after immersion in water. The density, taken from pieces of varying size, gave the following numbers: 7.825, 7.836, 7.747. Messrs. Guignet and Osorio found 7.750. These differences in the density of various specimens go to prove that there is no perfect homogeneity either in the structure or the composition of the metal. A fragment weighing 0.66 gramme, treated cold with nitric acid, diluted with six times its volume of water, dissolved in 48 hours, with a very feeble disengagement of nitrous gas, giving a green liquor. Iron, under the same conditions, gave a brown liquor.

On the same subject M. Boussingault makes the following note: "I wish to draw the attention of the Academy to the fact that the iron from Brazil is not oxidizable under simultaneous contact with air and water. Berzelius has stated in one of his works that meteoric iron resists oxidation. From this it could be deduced that steel could be preserved from rusting by adding nickel to it. I made numerous essays, with this object in view, during my last stay at the Unieux forge, in alloying steel with 5%, 10%, and 15% of nickel. The ingots, after forging and drawing, had a handsome appearance, and took a beautiful polish, but I found that these alloys, either as bars or filings, oxidized perhaps more rapidly than steel bar or filings destitute of nickel. I might, indeed, have spared myself the trouble of making these experiments, for Faraday and Stodart had already found that melting steel with nickel we get an alloy which has a very lively tendency to rust. Since then I have seen two meteoric irons, one from Lenarto, the other from Charcas, containing from 5% to 7% of nickel, filings from which oxidized very promptly under the double influence of air and water.

"Notwithstanding, it is beyond all doubt, that the specimen of Brazilian iron absolutely resists oxidation. This is evidently due to its composition—to the very large proportion of nickel it contains. Melting down a mixture of 62 parts steel and 38 pure nickel, an ingot was obtained in my laboratory, a face of which was smooth-filed and exposed to air and moisture which had no effect on it. Filings remained in tact under immersion, with the exception of two or three grains, which got rusty, which seems to indicate that the alloy which could not be stirred whilst in fusion, did not have an entirely homogeneous constitution."

A Simple "Mechanical Finger."

At a recent meeting of the S. F. Microscopical Society, Prof. H. G. Hanks described a very simple arrangement by which any microscopist, who has a mechanical stage to his instrument, may have the benefits of a "mechanical finger," without the cost of the elaborate mechanism which has been devised for the purpose required. Prof. Hanks said:

Let the microscope be placed in a vertical position and a suitable object-glass screwed on. Fix the parabola in its place in the sub-stage. Let it be pushed as far in as possible so that when elevated by the milled heads it will rise through the opening in the stage, with its upper edge above the surface. As it will not be immediately required it may be depressed, using the milled heads for that purpose. A glass slide, upon which the rough matter is laid from which it is desired to select an individual crystal or other object, may now be placed on the stage. The sliding pieces of the stage must then be separated as widely as possible and the stage forceps fixed in the usual position. If the objects to be picked out are small, such as diatoms, etc., a human hair must be placed in the jaws of the forceps, and so arranged that it will appear in the field and near the surface of the slide. The objects to be selected should be as near the center of the slide as possible. By turning the milled heads of the mechanical movements of the stage, the desired object may be centered, after which the hair must be readjusted without moving the stage. By elevating the sub-stage slightly, the slide will be lifted from the stage, the position of which can be changed by the mechanical movement, while the slide remains stationary.

When the end of the hair is exactly over the object, which is dimly seen out of focus, a turn of the milled head of the sub-stage lifts the slide until the object touches the hair and remains attached to it. When the sub-stage is lowered, the object remains suspended to the end of the

hair. The slide may then be removed and another substituted, to which the object may be transferred by simply elevating the sub-stage, the slide rising to meet the suspended object. If the slide has been gently breathed upon, the object leaves the hair and attaches itself to the glass. This applies only to minute objects. When the object is larger and too heavy to be lifted by a hair, it will be necessary to substitute a bristle and to wet the end of it; when the second slide is placed under it, a few minutes will suffice to evaporate the moisture, and the object will fall into the desired position.

The hair may be used to push away worthless matter which may surround the object desired. It is perfectly easy to push any portion quite out of the field, simply by using the stage movements while the slide rests on the parabola.

If a piece of fine aluminum wire, the end of which has been flattened by a pair of steel rollers, be substituted for the hair, and a low power used, a crystal may be lifted with as much ease as a lump of coal on a shovel. To prevent the object from being pushed before the chisel edge of the wire, a small piece of glass may be placed in the direction of the movement, against which the object is held, while the edge of the flattened wire passes under it.

It will be found difficult to place a hair firmly in the jaws of the stage forceps. This difficulty may be overcome by cementing the hair or bristle between two small pieces of thick paper, which the forceps will hold rigidly.

Nothing can be more simple than this device, and I question if any mechanical finger can be more effective. A few minutes will suffice to make it perfectly understood.

A NEW METHOD OF OBTAINING SKELETONS.—The help of insects is often called in by naturalists to produce skeletons of small vertebrate animals. A common plan is to place the animal whose skeleton is desired over an ant's nest. But these skeletons are generally dirty, and it may be imagined how much better it would be if the operation could be performed under water. Such a process has been discovered by a French naturalist. He finds that tadpoles are not exclusively vegetable feeders, but will eat meat when they can get nothing else. Indeed, a few days will suffice to accustom them to live on flesh without injury to their voracious appetite. They will then clean with marvelous exactness the bodies of small animals given to them. The discoverer of this plan has exhibited excellent skeletons of three kinds of lizard, three kinds of snake, two kinds of triton, and a larva of triton, obtained in two hours, the latter being quite an anatomical *tour de force*, considering the extreme softness of the bones of larvae of batrachians. The operators were a hundred tadpoles of frogs (*Rana fusca* and *agilis*). The number of tadpoles should be proportioned to the task, and the small animals should be given them skinned. The skeletons should be completed in two or three days at the most, so that the water may not destroy the ligaments. It is recommended that the tadpoles should be kept in half darkness and in a warm place.

"FLESH WORMS."—The *Demodex folliculorum* is a worm-shaped minute mite, which lives in the sebaceous and hair follicles of the skin in man and some mammals. M. Megnin has lately published a full account of it. It is said to be viviparous, the female producing small footless contractile larvae, without any mouth organs, which shortly after their birth acquire three pairs of short wart-like feet. After a change of skin a fourth pair of legs appear, as well as traces of a beak. After a second change the perfect demodex is produced, but still without the sexual organs, which appear later. Megnin distinguishes three if not four forms of these parasites, which, however, he prefers to regard for the present as varieties of a single species—*Demodex folliculorum*. The commonest of these appears to be that of the dog (var. *caninus*), which inhabits the hair follicles of all parts of the body of that animal; a smaller variety (*D. cati*) is found almost solely in the sebaceous glands of the ear of the cat; and a larger one (var. *hominis*) in the follicles of the human face. M. Simon also met with similar parasites in the glands of the margin of the eyelids in sheep (var. *ovis*); but no other writer has ever seen them there. In the dog the presence of these parasites, which occur in great numbers together in the hair follicles, produces a regular skin-disease or mange; but this does not appear to be transmissible to the human subject.

AMERICAN HISTORY.—A. S. Barnes & Co., of New York city, have undertaken an enterprise which will delight the hearts of the historical students of the country. It is the publication of the *Magazine of American History*. The purpose of this periodical is to supply to persons engaged in historical study a regular avenue of communication with each other and the general public. Each number will contain an original article on some point of American history from a recognized and authoritative pen; a biographical sketch of some character of historic interest; original documents, diaries and letters; reprints of rare documents, notes and queries in the well-known English form; reports of the proceedings of the New York Historical Society; notices of historical publications. The numbers of the magazine which we have had pleasure in examining, exhibit these valuable features, and we doubt not the publication will prove a success.

GOLD IN ALASKA.—The steamer *California* has arrived in Victoria from Sitka, Alaska. Purser Hughes reports that new gold mines are at Schuch, Alaska Territory, 70 miles up the coast, north of Fort Wrangel. At present about 60 men are at work taking out from \$3 to \$4 a day to the hand. The field is said to be large enough to support 5,000 men and borders on the coast. Canoes can take miners from Wrangel to the diggings in two days. A report says Wilson & Co. have struck ounce diggings. Silvers & Co., are sinking a shaft and have struck blue clay, in appearance like that found on Williams creek.

EMMA MINE.—Judge Barret, in the N. Y. Supreme Court Chambers, has granted an order of publication of summons in the case of James M. Townsend, Jr., against the Emma silver mining company, limited. This suit is brought to recover \$88,301.16, on a judgment obtained by Trenor W. Park against the company, in the Third District of Utah, May 22d, 1876.

MINING SHAREHOLDERS' DIRECTORY.

The Mining Share Market.

There is nothing of special interest to record of transactions in mining stocks, as the depression still continues in that branch of business. The fluctuations in prices are small, and the volume of sales light. This long-continued dullness in the stock market has a serious effect on all branches of business, as its effects are felt on all sides, and people seem to be waiting for a rise in the market for a revival of trade. The Constock mining interests, however, feel the effects more particularly. The mines continue to shut down and discharge men, so that considerable distress is experienced among the laboring community.

How severe this pressure is may be imagined from the following figures given by the Virginia *Enterprise*: A careful estimate of the amounts disbursed here monthly for work and materials by the American Flat mines which have shut down makes the sum total of \$57,000, and this is but a very small portion of the Comstock. The closing down of these mines has, however, taken that amount of money monthly from our circulation. A further careful estimate of the retrenchment in other mines on the lode where the number of men discharged and the amount of wood and timber used are known to the reporter, makes the total of about \$365,000 per month. It is, therefore, safe to say that \$420,000 less of expenditures are being incurred monthly on the Comstock than usual. In this estimate none of the mines are included which are simply doing work enough yearly to hold their claims. But where the work is being done the outlook is most favorable. From the Utah to the Dayton encouraging prospects are being encountered. Nor have these promising indications been confined to the mines now actively engaged in prospecting. Some of those shut down were compelled to do so at a time when everything was most favorable. Most of them are talking of an early resumption, and this is what is needed, both here and elsewhere, for without prospecting the mining would soon be confined to a few bullion-producing localities, and when the ore bodies now opened up were exhausted would cease altogether.

The following assessments have been levied since our last issue: Savage, \$1 per share; Jennie A. and Black Rock, 20 cents; Lucke Rock, two cents; Succor, 50 cents; Martin White, \$2; Comanche, (Benton, Mono Co.,) 50 cents.

The sales in the San Francisco Board for the week ending May 29th aggregated \$1,000,000.

No sessions of the San Francisco Stock Board were held on Wednesday, Decoration day. The Board also adjourned on Thursday morning.

ing in respect to the memory of Mr. Everett, an old member of the Board.

An advertisement has appeared asking all parties owning Crown Point stock, whether in their own names or otherwise, and who are in favor of reform and a change of management, to call at the office of F. E. Wilke, 429 California street.

THE *Enterprise* of the 27th says: The bonanza mines yesterday made the largest shipment of bullion yet. The shipment last week amounted to \$557,768.44, out of a total of \$568,720.81 shipped at that time. Last evening they shipped 134 bars, valued at \$538,657.32, being \$888.88 more than the week before. This is the return of another week's run, and shows how nearly even is the yield of the Consolidated Virginia and California mines from week to week.

ICE IN THE MINES.—Mr. Boston, head engineer of the Sierra Nevada, gives the information that quite a thick layer of ice is found daily around the exhaust of the Warring compressor used on the 1500-foot level in connection with a Foote blower. He thinks they could manufacture ice in the mine for one and a half cents per pound. In the Caledonia mine they have frequently to thaw out with hot water the drilling machinery which is run by compressed air.

THE Los Angeles *Herald* informs its readers that there was foundation for the rumor that the Southern Pacific Company were negotiating for the purchase of the Los Angeles and Santa Monica Railroad. The bargain has, in fact, been completed, and the transfer is to take place on the 1st of June. The motive of Senator Jones for disposing of the road is supposed to be found in the apathy of the people of Los Angeles county about its extension to Inyo.

THE furnace, assay office, stables and other buildings of the Jersey mine, which were offered for sale yesterday for taxes by the Sheriff were purchased by the County Treasurer for the county, there being no other bidders. The *Silver State* says the mine, without which the furnace is useless, is involved in litigation, hence no outsider cared to invest in the property.

THE Peck mine of Arizona was not sold to San Francisco capitalists because of the inability of the negotiators to raise the purchase money, some \$400,000. The owners of the mine will therefore proceed to push forward active operations, with the intention of extracting \$200,000 per month.

THE Secretary of the Navy has issued orders requiring candidates for the office of Navy Paymaster to enter upon a competitive examination before a board of officers, on whose report the appointment will be made. This has never been done before.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

COVER.—*Amador Ledger*, May 26: The new hoisting works at this prosperous mine are completed, and in active operation. They are among the finest works of the kind in the county, if not in the State, being equal to developing the mine to the depth of 2,000 feet, the reel holding 2,200 feet of rope. The new shaft is down 200 feet. Meanwhile the mine continues to open up splendidly. The ore body in the principal drift is now 22 feet wide, every pound of rock being sent to the mill. A clean-up was made lately from ore taken from this immense vein, and the yield amounted to the handsome sum of \$10 per ton.

LIVE OAK.—This week we paid a visit to this lively looking prospect, which is situated within the town limits of Sutter Creek. A shaft has been sunk to the depth of 30 feet, showing a regular foot wall and hanging wall, about 65 feet apart, between which small strings of quartz and gouge matter are found. A small pile of ribbon rock lay on the surface, in which rich sulphurets are seen, and which also yields a fair prospect in free gold.

BUNKER HILL.—It is pleasing to note that the ore in this mine has shown a decided improvement in quality of late.

BONANZA.—This mining property is looking better than ever. The shaft is 240 feet deep, the vein matter increasing in size and richness as prospecting continues.

GOOD HORN.—The shaft is free from water, and the work of taking out ore is progressing.

BUTTE.

GOSE DOWNS.—*Oroville Mercury*, May 26: For some time past we have heard nothing from the rich mines in and around the old mining town of Forestburg. On inquiring we learn that the mining is being done, and the shafts taking out and crushing the rock. They have good rock and a good mill and we don't understand why they stand still and consent that the moss shall grow over them.

SOLD.—The Armstrong mill and mine was sold last Monday by the Sheriff at auction and bought in by D. L. Brown, who formerly owned the Long's bar ferry, for the sum of \$5,000. It is considered a very cheap piece of property at that price, as it can be worked at all times during the year and yields good pay to the ton of ore crushed.

CALAVERAS.

RICU ROCK.—*Calaveras Chronicle*, May 26: Ore of unexampled richness is now being taken from the 1300-ft. level of the Gwin mine. We have never seen anything equal to it. The "streak" is about two and a half feet wide, and from present appearances will continue throughout the level. It is really the richest thing in the country.

UPPER COUNTRY ITEMS.—The company owning the Summit lead have recently had 100 tons of rock crushed. The amount obtained has been large, for the company intend to erect a new 20-stamp mill. Needhardt & Johnson recently crushed 50 tons of rock, which averaged over \$50 per ton. Golden & Smith have lately struck good rock in their mine at Bummerville. McBeth & Co., owners of a very promising lead, a short distance from West Point, are being well remunerated for their labors. All the mines at Skull Flat have out large quantities of ore. Crushing commenced as soon as the mill at Mosquito is completed, which will be in a few days. Work on the Anderson Flat mine is progressing favorably. Sundermyer & Co., proprietors of the celebrated Eureka mine, have out 250 tons of quartz on the dumps. We learn that the company have rented Clark's mill, and will commence hauling rock the first of next week. Brown & Bardsley, at Sandy Gulch, have recently struck rock in their mine. They will pay \$100 per ton. Potter & Co.'s lead at Mosquito, is undoubtedly one of the richest in the upper country district. Out of a piece of rock weighing a little less than 15 pounds they obtained \$300. Vein, two feet wide. The mining interests generally in the upper country region are flourishing.

EL DORADO.

CENTENNIAL HITES.—*Amador Ledger*, May 26: At Sutter Creek, the other day, we were presented with a curious specimen of gold-bearing pyrites of iron, taken from the Centennial Hites mine, in El Dorado county, just across the Amador line, about seven miles north of Fiddletown. The property is owned by the Hites Bros., who are developing it as rapidly as their means will allow. It is not uncommon to meet with crystals of iron pyrites in the neighborhood of quartz veins, but we have never before heard of a mine composed almost exclusively of them, as is the case with the one now under notice. The vein is some six or seven feet wide, the ore being quite loose. All that is required to be done is to take out lagging and the crystals will run into the shaft, where they are shoveled into the bucket and sent to the surface. One of the owners brought a small parcel of specimens to Sutter Creek. They are undoubtedly very rich in gold, the precious metal being visible in lots of the pieces, while the dust in the bag, produced by friction, fairly glittered with gold. Fifteen tons of this ore have been sent to the Bonanza mill, at Drytown, to be crushed.

INYO.

MICHIGAN MINZ.—*Coso Mining News*, May 26: This mine is between the Lucky Jim and Christmas Gift mines of the New Coso company, an excellent locality. The work done upon it consists of a shaft sunk upon the ledge to a depth of 60 feet and a tunnel run in upon the ledge from the east, 100 feet, connecting with the shaft. The tunnel was run by the Bastian Bros., and enough ore was taken therefrom to pay for the entire work. The ledge at the point of connection with the bottom of the shaft is six feet wide, there being a solid vein of 16 inches of excellent ore.

PANAMINT MINES.—A short time ago orders were received by Captain Messec, Superintendent of the Surprise Valley mill and water company, at Panamint, to suspend all operations upon the mines. On the day the orders were received, a strike of considerable importance was made in the Wyoming mine, at the depth of over 600 feet, of some two feet of the rich black metal found near the surface in that mine, and which produced considerable bullion worth \$14 the run, the mill being shut down for a thorough clean-up and some few repairs. A shipment of eight bars of fine bullion will have preceded this issue of our paper to San Francisco. These, in addition to the four bars shipped a short time ago, make a total shipment in value of \$14,500. This, for a new 10-stamp mill just commencing operations, we consider pretty fair work, particularly as the ore was put through just as taken from the mine and without any repairs. The shipment of the ores will be assured and only those put through that pay most now, while the balance will be kept back to be worked hereafter when freights, supplies, etc., are cheapened.

MINNETTA BELLS.—We found Mr. R. C. Jacobs, the Superintendent, busily engaged in retorting the amalgam collected after a 24 hr. run, the mill being shut down for a thorough clean-up and some few repairs. A shipment of eight bars of fine bullion will have preceded this issue of our paper to San Francisco. These, in addition to the four bars shipped a short time ago, make a total shipment in value of \$14,500. This, for a new 10-stamp mill just commencing operations, we consider pretty fair work, particularly as the ore was put through just as taken from the mine and without any repairs. The shipment of the ores will be assured and only those put through that pay most now, while the balance will be kept back to be worked hereafter when freights, supplies, etc., are cheapened.

These are some excellent mines between Grant's camp and the Minnetta, and an Eastern company has been or-

ganized to erect a five-stamp mill in Snow's canyon, so as to work the ores and test their extent and richness. These ores are free milling, being principally silver, but carrying 30% to 40% gold. We have seen two assays which go from \$700 to \$1,300 per ton. One of the ledges at the bottom of the shaft 30 feet deep is solid ore two and a half feet wide.

MONO.

BENTON MINES.—*Cor. Inyo Independent*, May 26: Mining at the Comanche has had a set back in consequence of the large amount of water; last Saturday all of the men were discharged excepting four, but the delay is only temporary. As soon as a pump can be rigged operations will be commenced. The Kerrick is furnishing a good supply of rich ore. There has been a rich strike in the Mojave, owned by Messrs. Leeper and Albright. The strike is about three feet wide and of a character that will net \$500 to the ton. The Diana is looking splendid. The Laura, Fryburgh, Alps, Eureka and other mines are looking excellent. Milling is at a standstill, as neither of the two mills here are running, through local causes. Both mills are expected to start up in a few days.

NEVADA.

BIG BLAST.—*Nevada Transcript*, May 26: We understand that the North Bloomfield gravel mining company put off a blast of 9,000 pounds of Judson powder in their claims at North Bloomfield on Monday evening last. It did splendid execution, and threw up the ground a long distance from the powder line. Where the blast was put in two drifts, was 65 feet long and the T's 96 feet in length. 9. W. White, agent of the plant, and Judson powder companies, fired off the blast by electricity.

A COMPANY of five men, all miners, not caring to work for wages any longer, banded together last week, and are now out prospecting for quartz ledges. They are determined men, and we feel confident they will soon strike something good. If more of the same kind would do likewise, we know we should have many valuable ledges added to those which are paying.

STRUCTURE.—*San Juan Times*, May 26: Evan D. Evans, Wm. W. Williams and James H. Reader, the owners of the Shady Creek mine, on Shady creek, near Hoyt's old crossing, have struck a rich piece of gravel which pays from 25 cents to \$5 to the panful of earth. This gravel claim covers about 50 acres of ground, with a creek front of about 3,000 feet in length. The gravel face is about four feet in depth to bedrock. It is covered with loam to about the same depth. Last summer the company ran a bedrock cut from the creek into their claims, but not of sufficient depth to reach bedrock at all points, consequently it is their present intention to make their cuts deep enough for all practical purposes. This work they will perform this season. They will place sluices in the cuts, and when completed they will own the best placer mine in the county, taking all their advantages of free water, good fall and easy mode of working their ground into consideration.

GRIZZLY BEAR MINZ.—*Grass Valley Union*, May 21: This mine is on Deer creek, below the Kentucky Ridge, and not far from the Forlorn Hope. We saw, yesterday, some very rich ore which had just been taken out of the bottom of the shaft. The ore shows free gold and very heavy sulphurets. The shaft is now down 50 feet and the ledge in the bottom is fully four feet wide. The ledge is enclosed in smooth, perfect walls. The Grizzly Bear is so situated that it can be worked through tunnels for a great many years, and there is plenty of water power available for machinery purposes. Ore there can be mined and milled for five dollars a ton.

WORKS STARTED UP.—The new sulphurets works, at Canada Hill, erected by Mitchell & Crosby, were put to work on Tuesday. The mining works will all be completed. How the Grizzly Bear put in a shaft by the gentleman named, will result in saving gold remains to be seen. They contend that their works are not of the nature of an experiment, but that they have completely demonstrated that they can work rebellious ore at little cost. We hope that their works will be a success. Meantime the firm of Mitchell & Crosby has been dissolved, or rather it has been merged into an incorporated company called the Pioneer Consolidated Company of California.

MURCHIE.—*Nevada Gazette*, May 26: The incline at the Murchie mine was nearly down to the bottom of the old works on Tuesday last, and it will be clear and everything ready for commencing the drifts to-day. It will not be long before this mine will be employing a large number of men. The present company propose to work it for all is worth. It has proved itself a valuable mine years ago.

TAUZ GOLD TUNNEL.—Some time back a title under the weather, so to speak, for several months and talk was at one time had of shutting it down, but the Superintendent has stuck to it, and we learn on Wednesday night a chute of ore was struck on the 740-foot level at a point never before worked. The indications are now looking favorable for a better state of affairs.

BULL-DOGS are getting about as common in our country as they used to be in some of the Southern States. One out near Newton has recently sent out thirty-one loads which yielded \$4,000, or \$150 to the load. Another is located in the village of Eureka South, and judging from specimens of the rock taken out five feet below the surface it will eclipse its southern neighbor. The ledge at the point reached is four feet in width, and the pieces from it which we saw were literally speckled with gold. The sulphurets in the ore are decomposed, and in their places free gold is stuck in chunks.

THE ROCK coming out at the New England continues to be rich. It is thought it will go in the neighborhood of one hundred dollars per ton. The ledge is large, and work is going on satisfactory there.

MONNIE'S works at the Providence are running like a top. The long furnace runs with the regularity of clock work, and does its work in a perfect manner. The success of the process is no longer uncertain. Bullion will be the outcome of the operation.

CROSBY & MITCHELL'S works are complete now. Steam was raised and the whistle blown on Tuesday last. Every thing is ready for work as soon as material can be obtained.

KITT'S mill, at Willow valley, is kept constantly running on custom rock, and most of it comes from new ledges which are being opened all over that section. It would surprise residents of town to see the number who are prospecting all over the district.

PLACER.

WORKING.—*Dutch Flat Forum*, May 24: Since our last issue we have been favored with rain and cool weather, which is favorable for our water supply. All the claims here and at Gold Run are being worked with vigor. The Moore Hill mine exploded a blast on Saturday, and is now under full headway again. The Polar Star continues washing constantly. The Southern Cross met with a little bad luck last week by having its incline and the upper end of its tunnel badly plugged. The Franklin is on again washing the gravel loosened by its large blast. The Baker is now under full headway, using water nine hours per day, and is removing the hard material which it is compacted with its normal rock. This claim is now working gravel that has never been drifted, and the result is looked for with considerable interest. The Star and Union continues washing. The Pacific is off cleaning up. At Gold Run the Cedar claim has cleaned up and is on again. The Bonanza, North Star and Illinois claims continue washing. The various ditches are conveying their full capacity of water, and it is believed that they will continue to do so for some time to come.

BLUE CANYON RAVINE MINES.—The Roaring Blunder mine is situated on the north bank of Blue Canyon ravine, being one and a half miles southeast of Shady Run, and contains a large strip of ground, which embraces an old channel or river bed. Prospecting was instituted by running cuts into the gravel found on top of the rim rock. By so doing, the mineral rock was found to suddenly dip to the hill's dip was followed a short distance, and although none of the gravel taken therefrom has yet been washed, it has nevertheless proven to be very rich, by the finding of a large number of specimens, two of which are worth \$100. A tunnel is now being constructed which will tap the bottom of the channel, and as it will be over

100 feet higher than the stream of Blue Canyon, a chute is also being constructed to convey the dirt where it can be washed.

ANOTHER STRIKE.—*Mountain Messenger*, May 26: Another rich strike has been made in a mining claim a few miles east of Forest City and just above the Mammoth Springs claim. A few pans of the first gravel taken out yielded enormously. We do not know the name of the claim, but its location is near the old Cornish ranch.

BORING FOR GRAVEL.—Pioche gold mining company, composed of wealthy men of San Francisco, is the first company in this State, we think, to resort to the process of boring to prospect a mine. Should this experiment prove a success, of which there seems to be no reasonable doubt, it will enable parties to prospect ground at greatly reduced expenses and be an immense saving in time. The running of costly tunnels or the sinking of expensive shafts, to ascertain if there be gravel, will be avoided. Holes of any size up to 10 inches may be bored. This process will also prove of great value in ventilating mines, etc. In fact, the uses to which it may be put in proving and developing the mining resources of the country are innumerable, and will doubtless prove of inestimable value. The possibility of boring for mines has been talked of these many years, but this, we believe, is the first company to practically test its efficacy.

OUR BONANZA.—The fabulously rich quartz ledge in the North Fork claim, at Forest City, has not petered as predicted it would. We feel compelled to announce that the ledge has every appearance of a "true fissure vein," and is still yielding almost fabulous amounts daily. On Tuesday last between \$4,000 and \$5,000 was taken from three double boxes full of rock. Work upon the ledge is being prosecuted with vigor; at the same time the company is pushing ahead for the gravel, which they will reach about the first of July.

TUOLUMNE.

CHAPARRAL.—*Tuolumne Independent*, May 26: In this mine, owned by Messrs. Schulz, Trout, Wagner & London, they have struck the shute, in the lower tunnel, for which they have been running about two and a half years. They are down 170 feet from the surface, and the pay rock is about two feet in width. The gold is very evenly distributed in the ore, and rock in which there is none visible to the naked eye will mill several hundred dollars to the ton. The point where the tunnel, the ledge is being struck is very rich, full of free gold and will go away up into the thousands.

OPENING OUT.—The north extension of the Louisiana mine, at Arastaville, known as the Virginia, promises to be property of great value. The vein is 14 inches and enlarging, pays for milling from \$23 to \$50 per ton, containing largely galena sulphurets, which assay from \$300 to \$500 per ton. In sinker mouth, strike work is being clear \$23; now going north towards the old shaft and value of ore increasing.

Nevada.

WASHOE DISTRICT.

CON. VIRGINIA.—*Gold Hill News*, May 30: The daily yield of ore has been increased to 500 tons of ore per day, which is being crushed by the mill as fast as extracted. The ore breasts and slopes on the 1650-ft level never looked better or yielded richer ore than at this time. The double winze sinking below the 1650-ft level to connect with the west drift from the C. & C. shaft on the 1750-ft level is down 12 feet, the bottom in very rich ore. The ore slopes on the 1150 and 1400-ft levels continue to yield their usual quotas of rich ore. The winze below the 1550-ft level has been connected with the upraise from the 1650-ft level, which greatly assists the ventilation of the lower levels of the mine. An east winze is about to be started on the east side of the ledge in the southeast portion of the mine. The west drift on the 1750-ft level from the C. & C. shaft is making fair progress. There is a strong and steady flow of water from the face of this drift—a much stronger flow than is now had in the bottom of the C. & C. shaft. Notwithstanding the loss of 30 stamps in the Consolidated mill for the month, the yield of bullion is amply sufficient to secure the payment of the regular dividend of \$2 per share.

JULIA.—Everything at the mine is running finely, both above and below ground. A personal examination of the ore vein on the 1300-ft level, made yesterday, showed the ledge to be not only large and well defined, but of an excellent character. The vein is over 300 feet in width, and has been penetrated to a distance of 100 feet, for a distance of 600 feet or more. The quartz is very solid, is of a lively, healthy, mineral-bearing description, large bodies of which would deceive a critical expert in a superficial examination, so closely does it resemble a portion of the pay ore of others of the Comstock mines. Four cross-cuts have been run from this lateral drift—two east and two west.

YELLOW JACKET.—Both drifts, east and south, at the 2200-ft level are 44 feet from the station. Water does not interfere. The syphon to carry the water from the pump station at the 1740-ft level across through a drift to the 1850-ft level of the Crowl Point and Belcher pump shaft did not prove a success; consequently the heavy main pump of the shaft has to be depended upon to raise the water to the surface. The large new working shaft of the mine, to the eastward, is now doing good service, and the water work is being done preparing for the new and powerful machinery which will soon arrive. This will be a double steam winch of sufficient power to sink the shaft a distance of 2,500 feet. The stone masonry foundation wall for the south side of the main building was commenced last Friday.

CALIFORNIA.—Daily yield, 500 tons. The ore slopes on the 1600, 1550 and 1500-ft levels are all yielding rich ore and showing no signs of exhaustion. The north drift on the 1650-ft level, the 1650-ft level, is steadily advancing, the face in hard blasting ore of a very rich character. Winzes Nos. 6 and 4, below the 1600-ft level, are each being pressed downward with all possible speed, the bottom of each in rich ore. Laying the heavy stone foundations for the large new air compressor at the C. & C. shaft is being pushed vigorously ahead. The yield of bullion is ample to secure the payment for the month of May of the regular dividend of \$2 per share.

SILVER HILL.—Work in the face of the north drift on the 650-ft level, which was suspended last week on account of the strong flow of water encountered, was resumed yesterday. The upraise from the 444-ft level is making good headway, the face in ore of a fair character.

GOULD & CURRY.—Work on the new pumps and bob at the base of the main incline is making good progress. The huge bob for the pumps at that station has not yet arrived, but will probably be on the ground ready to insert inside of four or five days more.

OHRE.—Daily yield, 40 tons of ore, keeping the Winfield mill steadily crushing. The station timbers are in at the 1900-ft level, and opening the station is making the best of headway. The south winze below the 1700-ft level is down 10 feet, and the west wall of the ore vein, and cutting some fine quartz in its descent.

BEST & BELCHER.—Cross-cut No. 1 on the 1700-ft level is steadily advancing to the eastward, the face in fine vein matter. Cross-cut No. 3 east is also making the best of headway.

SERRA NEVADA.—The south drift on the 1700-ft level is being pushed vigorously forward, the face still in very favorable ledge matter. The east and west cross-cuts from the main south drift on the 1500-ft level are showing some fine quartz and low grade ore.

UTAH.—The cross drift to the south and east on the 1100-ft level has penetrated the ledge a distance of 98 feet. The ledge, so far as developed, is solid quartz of the finest character. The vein is much better developed, and presents a vastly more permanent character than it did on the levels above.

MEXICAN.—The upraise from the 1465-ft level still continues in low grade ore. The north drift on the same level, following the east clay wall of the vein, is making good progress, and is cutting occasional bunches of good ore.

OVERMAN.—The north drift on the 1400-ft level, running in contact with the south drift from the Belcher, on the 1600-ft level, is making steady headway, the face in fine ledge material. The face of the south drift on the 300-ft level is in very favorable quartz and ore.

HOMESTRAD.—The surface work, which is a preparation for increased facilities for driving the shaft downward at a much faster rate of progress than heretofore, is rapidly approaching completion.

JUSTICE.—Daily yield, 450 tons of ore, keeping the mills all crushing to their full capacities. The ore slopes are looking well and yielding good milling ore at all points. The ore at the bottom of the winze below the 800-ft level continues of a fine character. The face of the main south drift on the 1000-ft level is still in ore of a good description, showing an improvement as the drift advances.

LEVATHAS.—A decided improvement is found in the south drift at the 400-ft level, one-half the face of the drift being now in fair milling ore.

SAVAGE.—The pumps are running smoothly and on a slow stroke, handling the water with perfect ease and holding it steadily at the depth required for the Hale & Norcross to work while repairing the cave in their main incline.

BELCHER.—Daily yield, 70 tons of ore, which is being crushed at the Santiago mill as fast as it is extracted. Sinking the main incline going steadily forward.

UNION CON.—The north drift on the 1300-ft level is showing some little improvement as it penetrates further and further northward. The quartz is coming in much stronger.

SUTRO TUNNEL.—Face of header in easy working material, consisting of ledge porphyry, with streaks of quartz and clay, giving some little increase of water. Careful and substantial timbering is called into requisition in passing through this matter. Total length of tunnel from mouth to face of header, last evening, 16,913 feet.

VALLETONA.—Sinking the shaft is making the best of progress, the bottom still in a fine character of ledge material.

IMPERIAL CON.—The north drift on the 2135-ft level is showing some very favorable quartz.

MORNING STAR.—Sinking the shaft is again being advanced at a very favorable rate of speed.

CHOLLAR-POTOSI.—Daily yield, 110 tons of ore, the assay value of which is \$24.60 per ton.

PROSPECT.—Face of main west drift at the 400-ft level in hard blasting rock, rendering progress somewhat slower at present.

NEW YORK.—The enlargement of the shaft is about completed. The finishing of the third compartment will make the shaft one of the finest on the Comstock.

BELMONT DISTRICT.

STRIKE IN EL DORADO SOUTH.—Belmont *Courier*, May 26: While some miners were engaged in timbering the new winze in the El Dorado South mine, last Thursday, they discovered a ledge that is very rich in silver ore. The place where this ledge was struck is about eighty feet from the lower level. The Superintendent has not yet ascertained the width of this ledge, as the air is bad and work there-fore necessarily slow, but this drawback will soon be obviated and the work of developing this new find will be pushed ahead at a lively rate. This is, of course, very encouraging, and the management feel confident that they have at last struck a bonanza. The machinery works splendidly, and everything in and around the mine going on smoothly.

CHARGE TAKEN.—A large body of rich ore has been struck in the El Dorado mine in raising the winze for air, which will be worked as soon as the connection is made. The Belmont also shows a decided improvement. Jefferson, Jet, and other districts in our vicinity are being prospected with energy, and in many cases show good results. Chlorides around Belmont seem to be doing well. We notice rich rock from various mines, and we feel satisfied that the "winter of our discontent" is passing away.

ELY DISTRICT.—The ore body in this mine still continues to improve and a large amount of ore is being extracted from every level on which there is being any work done, and is hoisting from the 1st, 3d, 4th, 6th, 7th, 10th and 11th levels. From some of these levels only a small quantity is hoisted, but in the majority of them the yield has been satisfactory. A large amount of ore is now on the dump awaiting shipment, and is being hauled to the mill as rapidly as possible. The prospects of the mine are very encouraging, every one having great faith in the present strike being permanent and that the future looks brilliant.

ALPS S. M. Co.—The usual force of men are at work; prospecting will be commenced on the lowest level next week. The Concord mill is running night and day on custom ore; two trains were dispatched this week over the Nevada Central to that mill, and to-day, Sunday, Monday and Tuesday, trains will be sent loaded with as much as can be carried. The Alps mill will shortly start on Washington & Creole and Mazepa ore, the necessary arrangements having been made for water to run that mill 14 hours daily.

ONE PURCHASE.—Mr. Theo. Hale received a dispatch yesterday evening from A. J. Blair, Superintendent of the Alps mine, from San Francisco, to the effect that the Alps company had closed the negotiations that have been pending for the Washington & Creole and Mazepa ground, and ordering them to take immediate possession and place a force of men at work. This is most acceptable news to our camp, as it will give employment to 40 or 50 additional men. It is known that there are thousands of tons of good milling ore in sight in the first five levels of the Washington & Creole, which has remained intact owing to the fact that the parties owning this ground owned no mill in which to work said ore, and the ore being of low grade (assaying \$40 to \$80), can only be made profitable by the parties who run the mills owning the property.

LEWIS DISTRICT.—Prospects.—*Cor. Tuscarora Times*, May 14: Your correspondent visited Lewis district last week, and was welcomed by the genial Superintendent, Sam Groves, of the Dunsany and Logan Con. M. Co., who conducted us through the mine. The new incline is down about 130 feet in good ore all the way. Sam says at the bottom of the incline he cannot tell how wide the ledge is, and it is all ore and no hanging wall in sight. The company intend to ship about thirty tons of ore to San Francisco for reduction previous to erecting a mill.

Work will be started on Monday, 7th inst., on the Deffiance mine, owned by Blossom, Middleton, Friley and Nealand, about 400 feet north of the Dunsany, where the boys intend sinking a shaft to catch the ore-shute now being worked in the Dunsany and Logan mine, and we hope they will strike it rich, as they deserve it. We had a long talk with Mr. Fitchett, who is interested in Lewis, and he says that Lewis is bound to come out all right, and is willing to take his chances out there.

OSCEOLA DISTRICT.

GOLD.—*Pioche Record*, May 26: We are informed by Mr. Smith, who arrived yesterday at J. N. Curtis's corral, that gold has been found in a gulch at Osceola district, which yields a bit to the pan. The gulch is just below a claim owned by Jim Mattson. The party is near Jeff Davis peak. Bonal forms of Pioche was the party who made the discovery, and 18 men are now at work there. The claim owned by Jim Mattson had always considerable gold quartz in it. Osceola district is in the immediate neighborhood of Shoshone.

WASHINGTON DISTRICT.—RE-PROSPECTING OLD DROUGHTS.—*Reese River Reveille*, May 5: Noah Wardle, a chlorider, has recently been re-prospecting the abandoned claims in the old Washington district, with encouraging results. Last week he brought in samples of rock from a ledge in that district, which

Continued from page 338.

boat I have ever seen; larger in fact than either the *Bristol* or the *Providence*. Many of the readers when at the Centennial saw part of her crank; it was exhibited by John Roach & Sons, near the American locomotives in Machinery hall. The engine is enormous, and has a 14-foot stroke. The boat is said to be in many respects the sister of the *Rhode Island*, now one of the fastest boats on the sound, easily able to walk away from almost anything going east of Hell Gate. She is in fact counted considerably better than a "20 mile per hour" boat. The *Massachusetts* is said to be capable of making 20 miles per hour; whether she can do it remains to be seen. Her model is not striking, while her upper works are something perfectly enormous. If she makes time, it will be because of her immense power. She has made one or two trips already, but the engine has hardly settled down yet in its bearings. I hear that she had to stop her engine for an hour off Point Judith one night this week, probably to cool the bearings. Last week the boat was open for the inspection of the press.

She is 340 feet long and 80 feet wide over the guards. The cylinder is 90 inches in diameter. The steam pressure is to be 40 pounds, which is 15 more than is carried by the *Bristol* or *Providence*. The wheels are 40 feet in diameter and 12 feet 6 inch face. Dip of buckets, four feet. Her interior finish and decorations are elegant. Her boilers are enormous in size, her stroke hole seeming large enough to hold bodily a 40-foot barn. The strap, on the lower end of the connecting rod weighs a ton, which gives a fair idea of her great size.

The Hunter's Point ferry have just on

A New Iron Ferry Boat,

Called the *Flushing*. She has inclined engine of the same pattern as those used both on that ferry and on the Fulton ferry. The other boats of this company have double decks, an upper and lower cabin; this boat, however, has but one deck, she seems to be very fast, and as ferry boats go, is good looking, though to use an old country expression, "she will never be hung for her beauty." The engineers on the river say "she turns a pretty wheel."

I suppose most of your readers are somewhat interested in the

Brooklyn Bridge,

And are wondering how it is progressing. Well, so far as the outside world can see it is standing still. Now and then we get a glimpse of a workman sedately crossing the airy foot bridge, or tying a knot in a rope, or some other similar operation, and now and then there are a party of gentleman and ladies crossing, and that is all. The work of making the wire is going on, both steadily and successfully. The material, I hear from the best authority, is proving much better than was expected, and is considerably above what the contract called for. The breaking strain of wire now turned out rarely falling to 3,600 pounds, while the contract calls for but for 3,400, a gain of 200 pounds in the strength of each wire.

A new bridge is now talked of, to extend across the river over Blackwell's island. The matter has at last taken definite shape, and plans, etc., have been presented. What its value is to be one can hardly imagine, since it is in a place where no one wishes to cross.

Probably many of the readers of the SCIENTIFIC PRESS have heard how last summer at one of our regattas,

A Catamaran—A Double Hulled Yacht,

Sailed by and around everything that was afloat that day, whether sail or steam. I think it was the *Meteor*; and how at another race in the sound another catamaran, the *Amoryllis*, did the same thing over again.

There are, I think, four or five of these boats now in the harbor. They are designed on the plan of the flying proas of the South Sea islanders. They are all alike in having double hulls, but differ in other respects.

Within a day or two I saw Herrishof's new boat, on this plan, show a sample of what she could do. Really it seemed more like a feather blown before a gale than anything afloat. When the wind struck her, she would flash away before it like an ice boat. As one of the fastest steamers on the river came alongside, the catamaran started away from her as though the boat had been at anchor. No steamer in the harbor could keep up with her, not even the *Mary Powell*, which with her new boilers, is said to have just beaten her best time of 25 miles an hour. I may at a future time have something further to say about these wonderful boats.

W. E. PARTRIDGE.

A Big Steal.

A few weeks ago a steam engine belonging to one of the smaller mines near Virginia City was removed by some parties unknown to the owners, who, upon learning the facts, telegraphed from San Francisco to Deputy Sheriff Treasurer at this place, to keep an eye open for any freight in that line which might pass through here. Nothing in the engine line was seen to pass through here, but somehow or other Mr. Treasurer concluded to go to Nevada City and investigate, but everybody was talking about Watson's new paper and he could get very little satisfaction, so he concluded to read the new paper awhile until the excitement subsided a little, so that people would talk about something else. About the first item he read was the following: "The Little Deer Creek gravel mining company, whose ground is situated at Unionville,

near the old Banner mine, have erected their hoisting works and commenced sinking an incline to prospect the gravel channel supposed to run through that section. The company is composed principally of Virginia City capitalists. Jacob Tonnor is Superintendent. We shall, from time to time, report the progress of the enterprise."

In company with the Sheriff of Nevada county, Mr. Treasurer visited the mine indicated, and found the engine in use to be the one wanted. A demand was made for the engine but possession was refused because the parties in possession claimed to have bought it. The matter will be adjusted in the courts.—*Colfax Enterprise*.

Mineral Wealth of Morocco.

In a paper read at the Society of Arts, Mr. A. Leared said the mining industry, which is at present systematically discouraged, might be prosecuted to great advantage in Morocco. The southern provinces are especially rich in minerals. The mountains which separate Sus from Draa abound in iron, and 50 or 60 miles southwest of Teradant iron of a very superior quality, used for making gun barrels, is found. In the same ridge of the Atlas mountains are several mines of copper combined with gold, and also rich silver mines. Lead, sulphur and saltpetre are found to the east of Teradant. Antimony and lead are also found in Sus. This does not exhaust the list of mines of which the Atlas is so productive. Possibly in the districts near the seats of power mining might be carried on by European capital and skill, by special permission of the Sultan. But in Sus and the southern districts the attempt would be hopeless until life and property become secure. During the discussion Mr. Rochusson said the main point of interest, he thought, was the mineral resources, which were not yet thoroughly worked, for between Cape Juby and Mogador there were great deposits of malachite and copper, and also what was known as the "Iron mountain," where there were deposits of iron such as were not dreamed of in England, and only about 35 or 40 miles from Mogador, the country between being almost flat. The state of the iron trade in Europe at present was not such as to encourage the investment of capital, but the ores on the northern slopes of the Atlas range were turned to account on a great scale by the steelmakers of Barrow, by Krupp in Prussia, and by the great French ironmasters, such as Schneider of Creuzot, and they would certainly find a better supply on the southern range. Undoubtedly its copper, iron, silver and nickel were sources of wealth which had been hitherto entirely overlooked. The Chairman asked how he would provide for working the iron. Mr. Rochusson said he proposed to export the ore, not to work the iron there. There was a great deal of copper working in Morocco, the whole of the copper coinage being made of native copper. The ironstone was also worked in the same way as the so-called Roman or Spanish Catalan furnace, which was again similar to the process employed in Bengal. Mr. Grace, having resided in Magador for the greatest part of the last 20 years, said he had noticed considerable improvement in the country during that time, but certainly its mineral resources deserved more attention. There were copper mines within 30 miles of Magador, some of which yielded 40 per cent. of metal, and he had sent home several parcels which had yielded 29 per cent. There were thousands and thousands of tons, but though they had applied several times to the Sultan, and had offered him \$1,000,000 a year for permission to work, or to form a company to work the mines on his account, his answer was always the same—that his fathers had never worked the mines and he would not. Lead ore they had been allowed to export under the name of antimony, for they dare not call it by its right name, and it yielded 80 per cent. of metal of very good quality, but owing to the great expense of transport it did not pay.—*London Mining Journal*.

THE WHITLACH-UNION.—Some day during the present week the work of constructing hoisting works on the old Whitchlach-Union, in Marshall canyon, will be commenced, preparatory to resuming work in the mine. In days gone past, the Whitchlach-Union was one of the banner mines of this district, containing a large ledge of rich ore, but the vein broke and was lost. The break was followed for 1,100 feet without regaining the vein; but, as Lander hill mining has demonstrated that a break perseveringly followed will lead to the vein, the Manhattan company are going to make another trial for the Whitchlach-Union. There is a shaft down on the mine a depth of 200 feet, but no work has been prosecuted therein for four years. The old hoisting works were removed to one of the Manhattan company's mines on Lander hill some time ago, and entirely new works will be erected. The construction of these and the prospecting of the mine involves the expenditure of a large sum of money, but the Superintendent has confidence that the money will be well spent and that the outlay will be returned with heavy interest by the product of the mine itself.—*Reese River Reville*.

TRANSPLANTING SKIN.—It is said that a celebrated American surgeon has recently successfully performed an operation which several eminent European surgeons had declined to attempt—that of removing an unsightly birthmark from the face of a wealthy Gothamite, and transplanting white skin from the arm of another person to take its place.

The Cheapening of Sewing Machines.

It is a matter for general congratulation that the future price of sewing machines will be but half of that which has been their cost hitherto. This will place these useful implements in the hands of hundreds who could not afford to purchase them at the old prices. The *Call* says: No event of the year has occasioned such general rejoicing as the expiration of the last patent on sewing machines. There is not a well-regulated family in the land where the machine is not a welcome visitor, and but few families, with the means at their disposal to make a purchase, that are not provided with one. But then, again, there are thousands of poor women in the land to whom the machine was a forbidden luxury so long as it sold at a price so high as to place it beyond the possibility of their reach. To this class \$40, \$60, \$80 and \$150 is a small fortune. Only the poorest machines could be obtained for the first-named figure—that is, of the kind of machine needed for general work—but it was as impossible to attain to the minimum as the maximum sum, and the fingers were compelled to perform, by the slow process of hours, labor which the machine manipulated in a few minutes. Now, it is asserted by those familiar with the subject, that machines of the finest finish can be manufactured and sold at a profit for \$25 and \$30. This will bring the machines of plainer construction down to \$10 and \$15, and render it possible for many a poor woman to own one.

But if the great masses of the people are rejoiced at the prospective reduction in prices, not so the former patent-holders and manufacturers. There are two establishments in the country that have been turning out the machines on a large scale, in one of which it is said \$12,000,000 are invested, and in the other \$8,000,000. These factories had their agents, who employed traveling solicitors, and between the two from \$20 to \$50 were divided in commissions, according to the quality of the article sold. From statistics on file in the Patent Office, it appears that during the single year, 1874, there were 410,000 sewing machines manufactured and sold by the five principal companies in the business in this country, besides about 120,000 more produced by ten other and smaller concerns. Of one kind of machine, nearly 1,000,000 have been sold, and of another 276,000 were sold last year alone.

The gains have been so vast to the manufacturers that they were enabled to pool a million of dollars with which to operate upon Congress to procure an extension of patent; but there was a powerful opposing sentiment, and they were defeated. Those who have accumulated large fortunes from the monopoly can afford to stand back, after twelve years of rich pickings, and let the public at large have a chance to enjoy the benefits of the invention. The loss to manufacturers will be more apparent than real. The bulk of profit was made by middlemen after the machines left the shops. A new scale will be adjusted, and if the manufacturer gets less for his machines than formerly, he will be enabled to make up a portion of the difference in the increase of his sales.

The Ore Buying Business in Colorado.

When the miners of Colorado began silver mining they were surrounded with many difficulties—chief of which was a dense ignorance of the entire subject. It can be truly said that hardly a man in the whole country knew what a piece of silver ore looked like.

When it became generally known in 1865-66 that we were surrounded by true silver-bearing veins of great richness, the natural impulse was to turn to Nevada for information on the subject of extracting the precious metal from the ore. The wonderful success of the Nevada mines excited our people and suggested the wildest and most extravagant dreams of wealth; but when the practical application of the Nevada formula was applied to Colorado ores, there was too often a hitch, which either resulted in total failure or made the production of silver very expensive. The fact at last became patent that Colorado ores were totally different from those of Nevada and required different treatment. Roasting and amalgamation were successfully accomplished but at heavy expense, and the progress made was exceedingly slow.

In 1872, Mr. J. O. Stewart was extracting silver from the ore, using the reverberatory furnace for roasting and pans for amalgamating. Palmer & Nicholls were performing the same operation with the Bruckner cylinder for roasting and barrels for amalgamating. They were paying \$1.05 for every ounce of silver contained in the ore after deducting 35 ounces for mill charges. This gave the miner \$995 currency for 1,000 ounces of ore, and at that time greenbacks were from 15% to 20% discount.

At this time General Marshall made an arrangement with Wells, Fargo & Co. which enabled him to purchase and pay for all the ore in sight at a better price than the miner had yet received. He formed a partnership with Mr. Charles A. Martine, (a man whose acquaintance with Colorado ores began with the beginning, and whose education made it worth something), and the ore buying business began. The ore was crushed, sampled and assayed, and shipped by the car-load to Europe. The time required to complete the transaction sometimes reached

90 days. They paid 85% of the value of the silver contained in the ore, and of course compelled the mills to change their prices, and even then got the cream of the product of the mines. While the concern did not own a jaw crusher, or have a place to put a pound of ore, they were able, with Mr. Martine's certificate attached to a car-load of ore, to make a sight draft for its full value. Their drafts were always "gilt edged." Mr. Bement, then running a Krom concentrator at the old Washington mill, did their crushing for a time, as a matter of accommodation. Afterwards they formed a partnership with Mr. G. W. Hall, who was at that time in the lumber business at the old Georgetown Smelting Company's mill, and had a crusher which he run for the accommodation of the miners. The concern has been moving smoothly and quietly along ever since and makes as little disturbance now as it did the first week of its existence. The miners of this neighborhood have taken \$2,000,000 out of their little office, and, as a general thing, have gone away believing that they had a square deal.

The business of ore buying is now a monopoly. The "honest miner" with a shirt-tail full of ore has eight different places to go and get the money for it, and if he has struck a bonanza and can bring a hundred tons a day, worth a thousand ounces per ton, he would find an ore buyer in every quarter of the town pleased to see him and ready to pay him a good price for every ounce of silver in it.

This is not intended for a puff for any one. We speak of this business because we recognize the fact that the present plan of shipping ore to distant markets has done more for the district and State than anything else. It dispelled at once the distracting doubts about reduction. It gave us, by the correctness of our assays, a standing and respectability abroad which enables us to command all the money necessary to pay for all the ore which we can take out. We think that the parties above named are entitled to that kind of credit which the world cheerfully awards to those men who suggest and lay the foundation of great things. It is with honest pride that we say that a Colorado assayer's certificate attached to a car-load of ore will command the cash in any place in America, England or Germany.—*Colorado Miner*.

Eberhardt and Aurora.

The report of Capt. Frank Drake, on the Eberhardt and Aurora property, White Pine, Nev., circulated among the shareholders, says the *London Mining Journal*, states that the past year has been to the company one of continued prosperity, and few mining companies have so promising a future. The ore extracted during 1876 was 9,328 tons of 13 cwt., and the total cost was \$113,409, or about \$12½ per ton. The ore seam or body extending from the Baxter chamber, the discovery of which was cabled you on January 3d, lies between the first and second levels, and passes on east near the central shaft. They have drifted upon it 50 feet, and still are following it eastward. At times it has looked very promising, but at present it is quite narrow, and not of so good a quality as that passed through a week since. Consequently, with this section of ground so little developed, what they may properly call reserves of ore in the mines at the present time are very limited. The air-compressing machinery and rock-drill ordered of Mr. J. G. Cranstan, Newcastle-on-Tyne, did not arrive on the ground till October 2d. The erection of the machinery occupied some two weeks, and the drills not fairly running before October 20th. After a little practice by the men in working the drills a good degree of progress was attained. The general character of the ground through which they have passed is firm, hard, lime rock, but it generally blazes well and only on occasional set of timbers is required. The size of the tunnel excavation is seven by nine feet; the length of the tunnel completed December 31st was 525 feet; February 27th, 808 feet. Cost of running the 525 feet, \$15,446, or per foot, \$29½. In conclusion he states that no mine was ever opened and its hidden treasures made available without, on the part of the owners, a good degree of faith. His belief in the future wealth of these mines is now certainly in a promising line of promotion to a demonstrated reality. He alludes to these common facts in the business of mining as a stimulus to the patience of all interested, while the deep explorations are progressing, and till their strong hopes are fully realized.

PEELSTICK HILL is a prominent mining point along toward the southern extremity of the great Eureka lode. The name is an old one and it is not the greatest share of the present population of Eureka who know how it came to be thus christened. In the winter of '59-'60, there was an inveterate prospector here by the name of Ben Virgin. Ben's name figures all through the early mining records of this district, and he probably located more claims than any other one man who ever lived in the camp. It was characteristic of him to blaze the trees, marking the boundaries of every new find, and he having made an unusually large number of locations and indulged his propensity for scarifying the trees in a greater degree than usual on the hill under notice, the boys as a take-off on him named it Peelsstick hill, and by that name it has since been known, both in history and law. One of the grandest properties in the district, the Hamburg, is situated on Peelsstick hill.—*Eureka Sentinel*.

Making Money Mining.

Nearly every one recognizes the fact that everything here in a business way depends on mining. While this is so obviously true, we regret to say that we have some among us who seem to lack faith in the business. Years ago we had old prospectors who were afraid of "digging the bottom out of their mines." If they made a sale they acted like one obtaining money under false pretences. Their heaven seemed to be a home in the States, and they looked forward to the time of their departure like a convict in the penitentiary.

Before the stable character of our mines was so thoroughly understood—before deep mining had developed the fact that there is no "play out" to a true fissure mineral vein, there was some excuse for croaking and lack of faith. While it may be true that there is a feverish uncertainty about the business—sudden and unexpected success too often making men loose their balance and act foolishly, still the business will bear the test of severe scrutiny by the coolest head. Compare it with any other calling—even farming, which we like to think of as the foundation of all things—and the miner has no reason to hesitate. We have men who wear themselves out, pinching and starving as they go, and we have the happy-go-lucky restless character who squanders the money when he finds it; but we have another man who coolly and quietly pursues the even tenor of his way with as much confidence as the Granger in his market garden.

The business is all right, but it will not do to try to make it successful by trusting to luck. Good judgment is necessary, and there is a good deal of hard work about it. But we honestly believe that the coal mining towns of Pennsylvania are not built on a better foundation than Georgetown. This fact we are glad to notice is gaining recognition not only at home, where citizens are settling down for life, but among Eastern capitalists, who are making judicious, and therefore remunerative investments in our mines.—*Colorado Miner.*

Tunnel Talk.

This country must have gold and plenty of it. One of the important resources for that important article in Grass Valley mining district. That district will be, some of these days, put in a shape that gold can be mined out cheaply, and at greater depths than are now dreamed of by our most sanguine mining men. A great tunnel will do this business, and in time such a tunnel will be constructed. In the course of a few years a company will be formed which will have for its object the running of a tunnel from somewhere below Forest springs, on Wolf creek, up as far as the neighborhood of the Eureka ledge, a distance of some three or four miles. Such a tunnel would drain an immense area of most valuable gold bearing quartz ledges, and would make it profitable to work what is now considered low grade ores. The immense expenses of pumping, growing greater every year as fuel grows scarce and as the mines increase in depth, would become comparatively trifling through that tunnel. The work of running such a tunnel will not be a work of such magnitude that plucky men need hesitate to undertake it. The improved rock drills of the day would make quick work of it, and for the most of the year water power could be used to drive air concentrators which would drive the drills. Just now we have no idea as to how the drainage tunnel company would get any pay for the work, and doubtless the necessities of the case will, in time, suggest something upon which arrangements for "pay" can be made. This tunnel could have lateral branches under Osburn hill and under North Star and other hills. The number of mines the tunnel would keep at constant work, and profitable work, is up in the thousands. Some practical man, with a long and level head on him, who can get the necessary capital to back him, will inaugurate the needed and valuable work we have suggested.—*Grass Valley Union.*

LIXIVIATION A SUCCESS.—From Mr. Holdredge, an attaché of the Ural company's mill, at Lone, who was in town yesterday, we learn that the leaching process has proven a success in the works with which he is connected. The works now reduce five and a half tons of ore per day, which give an average daily yield of \$500. The capacity for leaching is not equal to the crushing capacity of the mill, and on this account the stamps are only run 12 hours a day, while the leaching works are run the entire 24. It is the intention to increase the capacity of the entire works to 12 tons per day, to which end force pumps have been ordered from the East. The object of these pumps is to force the leaching liquor up through the pulp in the leaching tanks, and thus obtain a more rapid and thorough lixiviation. The ores from the mines of the Ural company contain a considerable percentage of gold, and to save this, the pulp is amalgamated on shaking tables after the silver is taken from it. Mr. Holdredge also informed us that Col. Raymond is energetically working his mines at Lodi. These are base-metal mines, and the ore is sacked and shipped to San Francisco, via Wadsworth. Ten tons is the average daily shipment, and the ore ranges in value from \$150 to \$400 per ton.—*Reese River Reville.*

USEFUL INFORMATION.

Portland Cement.

A writer in the *Polytechnic Review*, in the course of an essay on cements and artificial stone, has the following: "The English Portland cement, which has acquired a world-wide celebrity, is an artificial production, the special features of the manufacture of which are the following: Chalk and clay are ground together in water; the fine particles are floated away to other vessels and allowed to settle as a paste, which is thereupon collected, molded, dried, burnt, and finally ground. Again, there are certain porous, earthy, disintegrated rocks, which are found to be capable of cementing with lime in the natural state; that is to say, they do not require any preliminary preparation by burning as do the ordinary clays, it being simply necessary that they should be finely ground, in order that a thorough incorporation with the lime may be effected. These natural cements are generally of volcanic origin. The so-called pozzuolana and the trass are the best known of these deposits, both of which have been used from very ancient times. The pozzuolana, occurring on the coasts of the bay of Bayal and Naples—a species of volcanic conglomerate or tufa—was known on account of its cementing properties to the Romans, and by them largely employed. Vitruvius and Pliny both describe it, and state that it was mixed with an equal quantity of burnt lime for building under water. The same substance is very largely employed in the same manner at the present time. Trass is the technical name applied to the immense deposits of volcanic ashes, or tufa, occurring in the valley of Broll, not far from Bonn, on the Rhine, and almost identical with the other deposits of quite equal magnitude occurring at other places throughout the once active volcanic district on the left bank of this river, known collectively as the Eifel. The material was first utilized by the Romans upon their first conquest of Germany, and is still quarried upon an immense scale. It is ground in stamping mills, of which there is a number in the immediate neighborhood of the openings, and is brought into market in the form of fine powder. When required for use it is mixed with lime, to which sand is generally added. When the materials are all of good quality, equal measures of the powdered trass, lime, and sand make an excellent hydraulic mortar."

A New Process in Sugar Making.

It is stated that a new process for clarifying cane juice without the use of lime has been successfully tried by Mr. Eastes, the inventor, at the mill of Mr. Dart, of Indorocopy, in Queensland. The principles of the process have not yet been divulged. The canes are, however, ground in the usual manner, and the juice allowed to run in the clarifiers; here Mr. Eastes' operations commence, the invention consisting in the treatment of the cane juice with certain chemicals which materially alter the color and viscosity of the liquor, the increase in the quantity of molasses attendant upon the use of lime being avoided. At the trials the freedom of the liquor from glutinous matter was particularly noticed, the liquor feeling quite warm to the hand. When the liquor ran from the clarifying box to the cleaning battery, it boiled with a clear white foam upon it, and scarcely any skimming took place. Less steam was needed for boiling in the vacuum pan. In a report given by the *Queenslander* it is stated that a perfect crystal of large size was formed, and that had there been sufficient liquor to fill the pan the crystals would have been of an unusually large size. The curing was soon disposed of, the liquor—not molasses—running away to the tank after leaving a basket of 1,788 pounds of beautiful clear white sugar perfectly dry in three minutes. It is also stated that the green tinge of the sugar as ordinarily made from the same cane is entirely removed. The density of the liquor was 10° Beaume. It has been suggested that the clarifying agent is hypochlorite of sulphur, but Mr. Eastes asserts it to be perfectly innocuous, and that it might be partaken of in the form in which it is employed; it is also stated that there is no probability of the sugar deliquescing. One of the most important points is that the liquor running from the vacuum pans as a vehicle for the sugar is not molasses, but purely crystallizable liquor, which requires no further clarification, and can be returned, after heating, to the pan, where it is entirely converted into sugar equal to the first, and not, according to the *Queenslander*, a particle of molasses made. If the reports upon this process are true—and at present we have no reason to doubt them—Mr. Eastes' invention is one which will largely revolutionize the manufacture of sugar.

PATENT RIGHT NOTES.—A rather important decision was made in the United States District Court at Cincinnati, a few days ago, says the *Scientific American*, involving the standing of notes given for patent rights. Pennsylvania was, we believe, among the first States to enact a law requiring that such notes should bear upon their face the words, "given for a patent right," further providing that notes so distinguished shall, in the hands of any third parties, remain subject to all the equities between the original parties. The same law was subsequently enacted in Ohio and other Western

States for the purpose of stopping the frauds which have been from time to time committed by patent right dealers upon innocent and unsuspecting farmers. In the case heard before Judge Swing, at Cincinnati, the defendant offered to prove that he had been defrauded, and insisted that he was not bound to pay the note, and claimed that the present owner of the note, who bought it before due, was bound, under the Ohio law, to permit such a defence to be made. Judge Swing, however, took a different view, and pronounced the Ohio law unconstitutional, saying in substance that the insertion of the words, "given for a patent right" is no protection to the maker, and of no force whatever. He decided this upon the principle that such a law impaired the value of patent right property, a species of property created by the Constitution and laws of Congress, and as such entitled to all the protection given to any other property, and not properly the subject of individual discrimination. The Indiana courts have decided the same way.

MATERIAL FOR SHIPBUILDING.—The existing troubles between Russia and Turkey and the unsettled condition of other European powers growing out of these hostilities have already created a demand upon this country for timber suitable for shipbuilding, and the agents of several foreign powers are in New York for the purpose of purchasing such timber. The *Iron Age*, says: Two cargoes were recently shipped to France, and it is said that more has been purchased for Great Britain. But little live oak timber is in the market, the Government having nearly all of this timber stored at the various navy yards, amounting in the aggregate to about 1,200,000 cubic feet, though much of it is decaying for want of suitable places in which to preserve it. The usual method of preserving this timber is by submerging it in wet docks, and we have not a sufficient number of such docks to contain it; therefore the timber has to remain in the open air, and, in many instances, not even a shed covers it. Vast quantities of other timber, such as white oak, walnut, pine, etc., also lay exposed to the weather at several navy yards, and much of it is already unfit for use on account of being so exposed. Live oak timber, which is most used in shipbuilding, is cut in the winter, but does not become seasoned for a year or two.

INVISIBLE INK FOR POSTAL CARDS.—The *Deutsche Illustrirte Gewerbezeitung* proposes the general use of what may be called "postal card ink," for messages which are sent on such cards, or otherwise unsealed. A solution of nitrate or chloride of cobalt, or chloride of copper, mixed with a little gum or sugar, produces a "magic ink," which is made visible by warming, either by holding against the stove or over a burning match. Potassium ferrocyanide in solution may also be used; but this requires a developer, for which either copper or iron sulphate may be employed. With the former the writing will appear in brown, and with the latter in blue color.

TO PRESERVE THE NATURAL COLORS OF DRIED PLANTS.—The following method of doing this is given in a German pharmaceutical journal, and will interest botanists and others: Dissolve one part of salicylic acid in 600 parts of alcohol, heat the solution to boiling in an evaporating dish, and draw the whole plant slowly through it—prolonged exposure discolors violet flowers; shake off any excess of liquid, dry between blotting paper, and press in the usual manner. A frequent renewal of dry blotting pads, particularly at first, is desirable. Thus treated, plants are said to dry rapidly, furnishing beautiful specimens which retain their natural colors in greater perfection than by any other process.

GOOD HEALTH.

Comfort in Workshops.

The *Iron Age* takes up the subject of health conditions in our manufacturing establishments. The following quotation contains good hints: "In the summer time the greatest discomforts are the heat and too much sunlight. Awnings, shades, screens, curtains and other things of the sort that tend to the comfort of the workmen also greatly tend to the production of better work, and are of themselves quite inexpensive. Fans and blowers, where power is obtainable, pay their cost many times over. A workman cannot do his best, in a hot and stagnant atmosphere, and it is useless to expect it. A blower like Root's, or any of the positive displacement blowers, takes but little power and is much better on many accounts, than the centrifugal fans which are too often arranged merely to churn the air over and over again. Fresh air blown into the room is a great advantage, and in many instances this can be done at no great expense. Workshops are often made very uncomfortable on account of low ceilings, or low roofs upon which the sun beats down, converting the room beneath into a furnace. Sometimes this can be remedied by roof tanks, sometimes by a false roof on top, or, in other cases, by a space between the roof and the ceiling of the room below. In mills where there are furnaces, water screens are a great advantage, and should not be omitted. These are among the more important, and things that come to mind, and those which appeal directly to the workmen. There are many other things which do not make

as much show, nor appeal to the workman as strongly, but which tend to health and comfort, and which should by no means be omitted. Clean floors and clean walls are very important as affecting health, and should be looked after more generally. In many kinds of manufacturing much dirt is necessarily made, walls and ceilings are soon blackened, and, unfortunately, are allowed to remain so in most cases. We call to mind some workshops of this character where the whitewash brush is used frequently and the walls kept white and clean. The result is that everything about the place seems to be fresh and cheerful, work goes on more easily, cleanliness of the rooms seems to induce cleanliness of person, and there is a greater self-respect among the workmen in consequence, while the advantages to health are by no means inconsiderable.

Exercise for the Teeth.

M. L. Holbrook, M. D., in the *Herald of Health*, says: "There is very little doubt but that the human teeth have become through successive ages of civilization more fragile and liable to decay than is either pleasant or profitable. Just how much of this is due to lack of care and cleanliness, and just how much more to food, no one can tell; but it is evident these causes are among the chief, and it would seem reasonable that man in civilization should do something to prevent it. Now in barbarous tribes of men the teeth are generally sound, and yet a toothbrush and soap is never used, and this may be because their teeth are exercised more by hard food, and cleaned by the abundant flow of saliva which would naturally come from hard food. Man cannot, however, go back to a savage life, so he must contrive means for keeping his teeth so that they shall not decay. That one of these means is the toothbrush and tooth-soap is certain; but is this sufficient? We think not, and believe that exercise is an additional means of toughening the teeth and making them strong. But how are they to be exercised? Surely it cannot be done on soft bread and such food as is too often found on our tables. It may be that the eating of raw wheat would give the proper exercise, and we suggest that it be tried in this way: Each day let the teeth be exercised on a teaspoonful of clean, dry, uncooked wheat. Children become fond of it, and if chewed fine it is very sweet, and promotes the rapid flow of much saliva. Unless swallowed whole it cannot do harm. It must not be supposed that any effect, however, to prevent entirely the decay of the teeth weakened by ages of bad dietetic habits, can in one generation be effected, and so the dentist must for the present be called in to our aid.

"Speaking of dentists, let me remark that a good New York dentist told me the other day that the teeth of boys brought up in New York were much worse than those of country boys. The jaws are smaller, the teeth softer, and not always covered over with enamel. If this is so, it is a great misfortune to be born in a city. But the dentist admitted that if the boys and girls were to chew a handful of raw wheat every day, it would cure the defect, so let us try it. We exercise our horses, why not our teeth?"

Treatment for Cuts.

D. McAlpin writes to the *Builder* as follows: "Take a fine needle and a double thread, (No. 60 to 80), knot it, and sew up the wound immediately after it is cut; do not go deeper than the skin. If anyone can be induced to try this, they will never do anything else for a cut. It requires no wrapping up—just keep it clean. I saw it practiced in the workshop by one of the workmen 40 years ago, and was recommended to try it. I tried it a short time ago and it was quite satisfactory. By exposure to the air, the matter that oozes sets and hardens in a short time."

The editor of the *Builder* notes the above writer is partially correct, but not entirely, for the reason that he overlooks circumstances with which only surgical practitioners, by their large experience, can become familiar. When by a deep cut a small artery has been wounded, the closing up of the skin will not stop internal bleeding, and a swelling, inflammation and supuration may result, which may necessitate the opening of the cut again; therefore, when there is much bleeding, it is better to introduce into the wound at first some lint or its equivalent, and when the bleeding has subsided, then it may be sewn up. We ourselves, during our practice in former years, have had more than one case where a druggist had sewn up a cut, when, after a week of much swelling and throbbing pain, the re-opening of the wound, which had been healed on the surface but not from the bottom, became necessary. Wounds must heal from the inside outward, and as long as the inside is not healed, it is not only useless but a positive harm to close the skin. When, on the contrary, the wound is shallow and only skin-deep, or slightly more, the remedy of our correspondent is correct, and it is much better to sew up the wound with a few stitches than to cover it with a plaster and shut off the access of air, which is decidedly injurious. It is a most hurtful idea that it is good to shut off the air; on the contrary, the access of air must not be shut off; the skin is made to be in contact with the air and it will heal much better without covering, if dirt and dust is only kept out of it.

ADVERTISING RATES.	1 week.	1 month.	3 mos.	12 mos.
Per line.....	.25	.80	\$ 2.00	\$ 5.00
Half inch (1 square).	\$1.00	\$3.00	7.50	24.00
One inch.....	1.50	4.00	12.00	40.00

Four weeks are rated as one month.
Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

SUBSCRIPTION IN ADVANCE.—Postage paid—one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by registered letters or P. O. orders at our risk.

SAMPLE COPIES.—Occasionally we send extra copies of this paper to those we believe would be benefited by subscribing for it themselves, or who are willing to hand the paper and speak of its merits to others. We call the attention of such to our prospectus and terms of subscription.

WRITE FOR THE MINING AND SCIENTIFIC PRESS. We invite not only professional men, but practical miners and mechanics to contribute to our columns. All communications will be kindly treated. Authors, as well as readers, will be benefited by corresponding.

ADDRESS all letters to the firm, and not to individuals, members, or others, who may at any time be absent from our office.

Our latest forms go to press on Thursday evening.

LARGE CIRCULATION.

We print a great number of extra copies of this double sheet issue of the PRESS, which we shall send out as samples through the city and country, that our already large and choice circulation may be increased.

Thus we sow at home and abroad reliable information of the resources and progress of our new country, for the benefit of the whole community in the Pacific States.

The new hands into which copies of this issue fall, we hope will give it a fair examination, and if practicable, substantially assist in sustaining our enterprise.

In order to meet some of the additional expense of such an issue, a number of our first and best class of business men have co-operated, by giving our columns their business announcements, which are worthy of observation.

Dewey & Co., Publishers.

SAN FRANCISCO:

Saturday Morning, June 2, 1877.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Mechanics' Liens on Mines and Mills; Patents to Mines; The New Mines; Bullion Shipments; River Mining; Mine Model, 337. Cleaning Iron-Amalgam; The Gravel Mining Season; Day Laborers; The Suto Tunnel; Items of Interest from the Mines; Gold Saving Apparatus, 344. The Ball Steam Stamp; Deputy Mineral Surveyors, 345. Patents and Inventions, 356.

ILLUSTRATIONS.—Fig. 1. Perspective View of the Ball Steam Stamp, 347. Fig. 2. Front View of Ball Steam Stamp; Fig. 3. Side Section of Ball Steam Stamp, 345. Fig. 1. "Fault" in the Montezuma Mine; Fig. 2. Vertical Section of Montezuma Mine, New Mexico, 346. The Price Excavator with Draper, 347. English Portable Straw-Burning Threshing Engine, 348.

CORRESPONDENCE.—A Sketch of the Mining in Plumas County, 338. Notes from New York, 338-42. New Mexico, 346.

MECHANICAL PROGRESS.—Cold-Chisels; Iron Cross-Ties; Joints for Steam Pipes; Progress of the St. Gothard Tunnel; Steam on English Streets; Proposed Wholesale Emigration of British Iron Workers; Removing Scale from Flues; Horse Shoeing; No Strength in Surplus Metal, 339.

SCIENTIFIC PROGRESS.—Experiments with Native Iron; A Simple "Mechanical Finger;" A New Method of Obtaining Skeletons; "Flesh Worms;" American History, 339.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments, Meetings and Dividends; Review of the Stock Market for the Week, 340.

MINING SUMMARY from the various counties in California, Arizona, Idaho, Montana, Nevada, Oregon and Utah, 341-48.

USEFUL INFORMATION.—Portland Cement; A New Process in Sugar Making; Patent Right Notices; Material for Ship-Building; Invisible Ink for Postal Cards; To Preserve the Natural Color of Dried Plants, 343.

GOOD HEALTH.—Comfort in Workshops; Exercise for the Teeth; Treatment for Cuts, 343.

GENERAL NEWS ITEMS on page 356 and other pages.
MISCELLANEOUS.—A Big Steal; Mineral Wealth of Morocco; The Whitlatch-Union; Transplanting Skin; The Cheapening of Sewing Machines; The Ore Buying Business in Colorado; Eberhardt & Aurora, 342. Making Money Mining; Tunnel Talk; Livestock a Success, 343. A Hint, 345. Blowing Up a Monitor; A Woman's Generosity, 346. Excavating Machinery; New Section of Central Pacific Railroad; Supreme Court Decision on the Tax on Mines; Soldiers' Additional Homestead Entries, 347. An English Straw-Burning Engine; Reception of the Microscopical Society; No Underground Gas; An Accident Fund for Railroad Hands, 348.

Cleaning Iron-Amalgam.

In working certain classes of ores it frequently occurs that, under certain not well understood conditions, the iron enters the amalgam when amalgamated in iron pans, making cleaning in the usual way impossible. It seems that the iron does not come from the ore but from the shoes and dies of the pan; otherwise it could not be explained why no iron-amalgam is obtained from the barrel amalgamation, at least never to such an extent as to form iron lumps in the crucible when the retorted amalgam is subjected to melting. This iron-amalgam seems only found in the case of roasted silver ores and raw gold ores. It is very magnetic, and the iron only loosely combined with the quicksilver, so that simple mechanical treatment, such as rubbing or grinding, is enough to separate the iron from the quicksilver, but this is too slow for practical work.

In answer to an inquiry it may be stated that there are several different ways of treating this iron-amalgam, but that described by Mr. G. Kustel is quick, cheap and perfect, and is as follows: A flat-bottomed pan like Knox's is put in motion without any water in it, and a bucketful of sifted ashes introduced. The well strained amalgam is then thrown in gradually, piece by piece, in proportion as it turns into powder. If the mixture assumes a dark color, or if the pulverization commences to go slow, another bucketful of ashes is added, and so on, until about 300 pounds are pulverized, which is effected in about half an hour. The gray, heavy powder is then taken out and another lot of 300 pounds of amalgam managed in the same way, and so on. In case the ashes are moist, a reaction in the mass is observed by the increase of temperature to a considerable degree. After the mixture is finished the powder is allowed to lay for an hour undisturbed, then some water admitted into the pan so as to cover the bottom about an inch deep. While the miller is in motion the amalgam powder is introduced by means of a scoop until about 800 pounds are charged. Water is added, if necessary, but not too much. Quicksilver is generally not required unless the amalgam was strained very hard. After a while the amalgam becomes more liquid by losing the iron, which blackens the water. After an hour's grinding some amalgam is taken out and examined, and if not quite clean another hour will do. A quarter of an hour before the discharge, more water and quicksilver is added—the quicksilver only for the purpose of easier discharge. It is not exactly necessary to work with charges of 300 pounds. If the supposition is correct that the iron comes from the shoes and dies of the pan, then if a certain kind of ore is inclined to form iron amalgam, this could be prevented by omitting the grinding, and in treating raw gold ore the grinding is indispensable, and in this case, if iron amalgam is formed, an addition of ashes to the ore would probably keep the iron from entering the amalgam, as the ashes are the means of separating it. Treating silver ores, this last remedy could not be used for the same purpose, as too much of it would injure the amalgamation.

The Gravel Mining Season.

The recent rain and cold weather in the mountains has been favorable to the gravel miners, tending materially to prolong the water season. The gravel miners will not make so poor a season's work as many persons suppose they will, for although the light fall of snow has made the runs of the large mines comparatively short, they have been under no expense in keeping their ditches open. The ditches supplying water have been running free for the whole winter, and no men have had to be employed to shovel out snow as is usually the case. There have been no heavy slides to carry away ditches or flumes to cause expense, so that although the season is shorter expenses are less than usual this year. The Grass Valley Union says, however, that the open winter has been rather hard on a very large number of the population of Nevada county by depriving them of work in repairing and keeping flumes and ditches in running order. It is said that up on the heads of our big canals the people are pretty hard up for coin just now, having been unable to obtain work during the winter. However, compensation is likely again to come into that population in the way of summer work. It is very probable that more than one of the great companies owning gravel mines and water ditches will soon begin to construct more reservoirs to be used in saving water. That will employ the men who live in high mountains, they being experienced in such work.

In some parts of the State the season has been so short that the miners have had to stop work, but in the districts where heavy operations are going on most of the claims are still washing. The open winter has led a good many miners to turn their attention to river mining, the low stage of the water allowing them to wing-dam in places where it has been impracticable for many years. As to the quartz miners, the season has been favorable for them in the State, as they had little or no surface water to contend with, and the mildness of the winter has allowed many mines to be worked continuously which ordinarily suspend work part of the time in winter. Altogether the outlook for California mining interests is very favorable.

Day Laborers.

The hard times in the East are driving many people from there to this coast who are in hopes of bettering their condition by the change. The emigrant trains are coming in every day and it is becoming a difficult question what to do with all this extra population. The majority of them are almost destitute when they arrive and must find employment immediately. Unfortunately these people are coming at a bad time for us and themselves. We are passing through a season of business depression—not so bad perhaps as elsewhere, but pretty bad for this part of the world—and the dry year, combined with the depression in mining affairs, makes it bad for the laboring people who are in need of employment. A good many of the immigrants coming without any means must become a burden to the community. California, and in fact the whole coast, is overrun with laborers out of employment, and unless they have a little money to make their labor productive those intending to come had better stay where they are for the present.

The truth of the matter is that just now there are more laborers here than we know what to do with. People with small capital to go into farming, fruit raising, mining or any other business are all very well, and the more of this class who come the better; but laborers who come in hopes of getting employment will find it pretty hard times. Over in Nevada there is a large class out of employment who find it impossible to get anything to do; and in California it is much the same. In this city, where most of the people come, there is more distress from lack of employment than most persons imagine, and the increase of population seeking work of course makes matters worse. Fortunes are not to be made here in a day any more than in any other part of the world, though many think the contrary; and capital is just as necessary to get into business as it is anywhere else. Our climate is better for poor people than the East, as the winters are not so severe, but employment is scarce just now, and it is no place for people to come without means at present. Those who intend to settle in agricultural pursuits will find plenty of opportunity, provided they have some means, but farms are not given away here any more than anywhere else, and it takes labor to make them pay. What we want most is capital to develop our resources; labor is now more abundant than is desirable.

The Suto Tunnel.

Considerable interest is now being taken in the progress of the Suto tunnel, as it is advancing quite rapidly towards the Comstock, and is only 2,800 feet east of the workings of the Savage mine. At the date of the last measurement the total length of the tunnel was 16,913 feet. The Enterprise is authority for the statement that the tunnel has, during its progress thus far, cut twelve separate and distinct ledges, yielding assays from \$2 to \$20. One of them was 112 feet in width; yet not a foot of prospecting has been done in either side of the tunnel. These statements are of interest as showing the immense lateral extent of the Comstock deposits. Other ledges may yet be struck by the tunnel in its course, any or all of which may be worked on the completion of the tunnel when they have time to turn their attention to mining.

At present, of course, the whole energies of the company are directed to putting the header along as fast as possible, so as to get at the Comstock. There is not so much opposition to the project as formerly among the mine owners and property owners of Virginia and Gold Hill, and it is conceded that the tunnel will save great expense in draining the mines. Still they object to the two dollars per ton royalty on ores; but if it is proved that the tunnel will drain and ventilate the mines, they can afford easily to pay that sum without grumbling. The projectors of the enterprise have shown indomitable pluck and energy in carrying out the plan amid so many difficulties, and even if the tunnel is not constructed as it should be, as some aver, there will be plenty of opportunity to enlarge, strengthen and improve it, when the Comstock is reached and funds are more plentiful.

MECHANICS' INSTITUTE ELECTION.—The regular ticket for this election, which takes place June 4th, 1877, is as follows: H. L. Hutchinson, scale maker (of Fairbanks & Hutchinson); George F. Allard, civil engineer; L. L. Blake, blacksmith, (of Baker & Hamilton); Columbus Waterhouse, wheelwright (of Waterhouse & Lester); James Duffy, manufacturer white lead and paints (of Whittier, Fuller & Co.); P. B. Cornwall, President Black Diamond Coal Mining Company; Henry S. Smith, machinist (Aetna Foundry). Polls open at the rooms of the society from 12 M. to 6 P. M., and from 7 P. M. to 9 P. M.

THE PIONEER MINING Co. are prospecting the ground in the old Galloway ranch, Sierra Co., by boring to strike the channel, instead of sinking a shaft. The machinery now on the way will bore an eight-inch hole. When everything is favorable a shaft will be sunk. If the boring machinery is economical, this is a good way to prospect such ground.

Items of Interest from the Mines.

We give below items of interest from prominent mines, most of which are collated from letters of the respective Superintendents on file at the offices in this city:

The incline station at the 1900-foot level of the Ophir is completed.

Preparations are being made for cross-cutting on the 1700-foot level of the Bullion.

They are laying the foundation of the hoisting works in the Watt mine.

The last clean-up of the Eureka (G. V.) was 175 ounces of amalgam.

A letter from the Empire (Idaho) says: Mine is improving daily. As soon as I can get the mine open, which will take 30 or 40 days, it will produce large results. I will, in the meantime be able to pay more than current expenses out of ore taken from the drifts.

Chollar turned out 637 tons of ore last week, averaging \$24.20 per ton.

From the Manhattan word came that during the last 14 days, ending Saturday night, May 19th, the mill reduced 267 tons, the assay value of which is \$44,667.76. At the Curtis shaft the stope on the 474-foot level has increased its yield of ore considerably, and nearly all the ore being worked at the mill comes from this stope.

The Superintendent of Con. Virginia in his weekly letter says: The ore breasts on the 1400-foot level are looking exceedingly favorable. On the 1500 level the drift south from the shaft has been reopened 40 feet. We expect to reach and ventilate the south ore body on the level below by the end of the coming week. On the 1550 level the ore breasts continue to look favorable. The work of enlarging the south drift and main air passage is being continued. We are now engaged in running a new drift from the south drift at the southern point of our ore body. Its course is south and east of our present ore stopes. A well-defined east wall has now been reached in this locality. A winze will be sunk from this drift to ventilate the east side of the ore body on the level below. Connection was made to-day with the winze connecting this level with the 1650-foot level. On the 1350-foot level the ore breasts are opening out very favorably.

The Golden Chariot mine is sending to mill 40 tons of ore per day, assaying \$86 per ton.

They are getting out high grade ore from the Paymaster lode of the Martin White company; an assessment was levied this week.

The 1000-foot level, south drift of the Justice, continues very promising and yielding a very fair class of milling ore. The full width of the ore body is yet unknown, as there is ore on either side of lateral drift. In due course of time a drift will be started to explore the full width.

Gold Saving Apparatus.

Mr. D. Beaumont, of Sacramento, has patented through the MINING AND SCIENTIFIC PRESS Patent Agency, an improved apparatus for saving the fine particles of gold, silver, mercury and sulphurets, which are contained in tailings and loose earth. The improvement consists in combining with a mining sluice or flume, two branch sluice-ways, each of which leads to a vertical penstock, the lower end of which terminates in a tank of quicksilver. The branch sluices are arranged so that either one can be closed so as to direct the material which is passing down the sluice or flume, alternately into one or the other, for the purpose of cleaning up. A tank for containing clean water is mounted above the branch sluices, so that clean water can run through the closed sluice for washing and cleaning the accumulated material. The lower end of each penstock terminates in a box or cavity which is partially filled with mercury, so that when the material which enters the penstock has accumulated to a sufficient height, it will be gradually forced down into and through the mercury so as to rise in the box outside of the penstock, and be carried away down the extension or lower sluice which leads from the box. During its passage through the mercury, the fine particles of gold, mercury and amalgam, contained in the tailings and earth, will be brought into intimate contact with the mercury and amalgamated, while the lighter portion will be carried away down the overflow sluice. The sulphurets being heavier than the water or earth will also accumulate in the box upon the mercury.

In operation the boxes or receptacles will be partially filled with quicksilver and the tailings directed into one of the branches by closing the entrance to the opposite one; the tailings will then be conducted into the penstock, where the column of water will force them down under the mercury so that they will pass through the openings below the penstock and rise to the surface of the mercury in the box outside. During the passage of the tailings through the mercury the fine particles of gold, etc. will be amalgamated and be retained in the bottom of the box, the sulphurets will collect on the surface of the mercury, and the worthless material will pass off down the tail-race.—As before stated, one box can be kept at work while the other is being cleaned up.

The trial of John Paul on a charge of stealing bullion from the California mine was concluded at Virginia last week. He was acquitted of grand larceny.

The Ball Steam Stamp.

During the past 20 years many attempts have been made to improve the crushing machinery for working the ores found so extensively in this country, and the application of steam to accelerate the velocity of stamp batteries, has received a large part of the attention given to the various modes of improvement. In most cases where steam has been applied to operate the stamp, the stamp stem has been arranged to pass into the steam cylinder and form the piston-rod, the valve for admitting steam to the cylinder being operated by a cam or other arrangement connected with the stamp stem and almost without an exception the batteries so arranged have proved a failure. Stamps of from 200 to 400 pounds weight, with from two to four heads in a battery, has been the size generally adopted in these experiments.

The Ball steam stamp herewith illustrated, was first introduced into the gold mines of North Carolina, where they worked successfully until the mines were exhausted. More than 20 years ago, two heads of the Ball steam stamps were erected for crushing copper ore at the mines of the Copper Falls mining company, Michigan, and they have been successfully operated to the present day. Many improvements have since been made in the Ball stamps, increasing their efficiency and durability.

A stamp of the smallest size and latest pattern was in Annex No. 3, Machinery hall, at the Centennial Exposition, where it was shown in operation occasionally during each day, its capacity being 15 to 20 tons of ore, when using the finest screens. In the accompanying figures, Fig. 1 (see page 337) is a perspective view of the No. 5 or smallest size stamp, and Figs. 2 and 3 are front and side views of the No. 1, or largest stamp.

The permanent foundation is composed of several courses of timbers, the top course being shown at A A. The course below this are made up of similar timbers, each row alternating in direction. Spaces are left between the timbers which are filled with concrete, making the foundation more solid and protecting the timbers from decay. B B are two cast iron sills, having broad bases which rest on the top of the foundation and support the whole of the upper part of the stamp. The sills are secured in position by bolts which pass from them down through to the bottom course of the foundation timbers. C C are two wooden sills on which rest the wooden sills, E E, which carry the two vertical posts, F F, to which the principal part of the machinery is bolted. The bed plate, G, and mortar, H, are carried on the spring timbers, I I, which are independent of the sills, C C, and E E, and which are elastic to a certain degree.

Upon the center of the bed-plate, G, stands the mortar, H, which is held in position by guides which work in the ways a a; these permit a vertical motion to the mortar when the timbers, D D, spring back after each blow of the stamp. The lower portion of the mortar, H, is circular in form, the upper portion being oblong, with a flat top and vertical sides; on the front and back sides are inclined openings for receiving the screens. The mortar is cast in one piece, and is lined throughout with hard iron linings made of a mixture of the hard irons. I I are two feed hoppers bolted to the top of the mortar and through which the ore is fed. J is the water urn through which the water is admitted to the mortar. K K represent the screens, which are secured in the inclined openings in the front and back sides of the mortar. L L are hoppers for the discharge of the crushed ore and water. M is a pipe for conveying water to the mortar. N is an iron frame bolted to the posts, F F, and having two boxes, O O, through which the stamp shaft, P, works. A revolving clamp and pulley, Q, having feathers which work in splines in the shaft, P, is turned by a belt giving a rotary motion to the stamp, both during its ascent and descent.

The stamp-shaft, P, is round, and, in the small machine shown, is four inches in diameter, the other four sizes having shafts five, six, seven and eight inches diameter. The shaft is made of wrought-iron and is finished all over; it works in the boxes, O O, and passes downward through the water-urn, J, into the mortar. The lower end of the shaft is enlarged to form a head, to which the stamp-shoe is keyed. The stamp-shoe is made of the same mixture of iron as is used in the linings of the mortar. They vary from six to seven inches in thickness, and, instead of being made cylindrical, have two flat, parallel sides. The width of these, for the several sizes, varies from six and a half to 14 inches, and the length from 10 to 22 inches. The die is a frustrum of a cone, from six to seven inches thick, and the upper surface is always a little larger than the largest diameter of the shoe. The upper end of the shaft has a circular flange, to which the bonnet, R, is bolted. The steam-cylinder, S, is bolted to the check-pieces, T T. The piston-rod, U, passes downward through the bunter-beam, V, into the bonnet, R, where it is held between rubber springs, which prevent any shock to the piston-rod or piston when the stamp strikes the ore in the mortar. A rubber spring in the bunter-beam, V, arrests the upward motion of the stamp and piston when too much steam is admitted into the cylinder. By this arrange-

ment, the danger of knocking out the upper cylinder head is avoided. The steam-chest, W, contains a common slide-valve, which admits the steam to the cylinder. In order to produce a quick downward movement of the stamp-shaft, the eccentric, e, by the intervention of the elliptical gear-wheels, e e, is given an increased velocity in that part of its revolution when the steam is admitted to the upper end of the cylinder, admitting the steam at full pressure and forcing the stamp down much quicker than it would fall of its own weight. The lower end of the cylinder is counter-bored, so that if the workmen neglect to feed the ore in sufficient quantity and allow the shoe to come too close to the die, the motion of the piston is arrested before it goes so low as to knock the lower cylinder-head out, and before it can again be started, the piston-rod and stamp-shafts have to be lifted to their proper positions. The valve is operated independently of the motion of the stamp by a belt on the pulley, e,

arranged as to always have a quantity of ore on the die, and as the shoe and die wear out the depth of ore on the die increases. The piston and piston rod are further protected from the concussive action by the use of a cushioned connection between the piston rod and stamp shaft, and also by the mechanical construction of the steam cylinder, which does not permit the stamp to continue in operation unless sufficient material is kept in the mortar to prevent the shoe from coming in contact with the die, or the piston going so low as to strike the cylinder head.

With the exception of the power necessary to drive the slide valve and rotate the stamp shaft, the machine is self-acting, the steam cylinder, which is a part of the machine, serving to do the stamping.

In the machines now in use this power is supplied by the machinery adjacent to the stamps, the auxiliary engine being driven by the exhaust steam from the stamp.

FIG. 2. FRONT VIEW OF BALL STEAM STAMP.

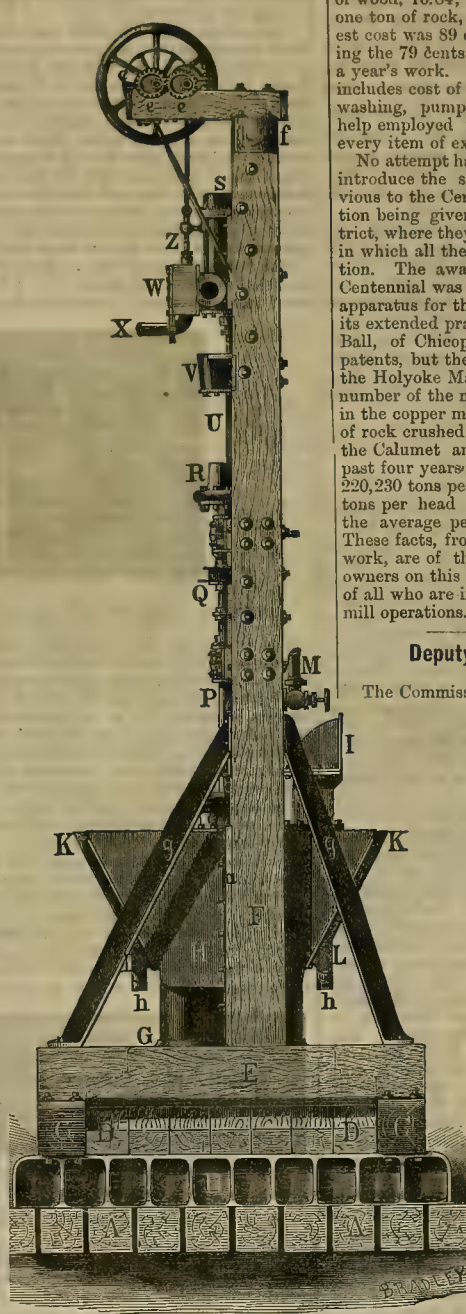

FIG. 3. SIDE SECTION OF BALL STEAM STAMP.

necessitating a small amount of power from an auxiliary engine. Power from the same source is also necessary to turn the stamp shaft by means of a belt on the pulley, Q. The diameter of the steam cylinder in the small machine shown is six inches, and having an extreme lift of 18 inches. Steam at a pressure of 70 pounds per square inch is sufficient to drive it 120 strokes per minute, the power necessary being about eight-horse to crush from 15 to 20 tons of copper ore per day to coarse sand, or the same amount of gold or silver ore to the required fineness.

The largest or No. 1 size, has a steam cylinder 12 inches in diameter, and 28 inches extreme stroke. The stamp shaft and shoe weigh 4,500 pounds, and when run at the rate of 90 strokes per minute will, it is claimed, crush an average amount of 120 tons per day of 24 hours.

In the construction of the machine a great deal of attention has been given to the important point of rendering the working parts as free as possible from the shock due to the concussion of the stamp, and has been provided for by placing the mortar on spring timbers, which are disconnected from the frame carrying the cylinder and other parts. To prevent the crystallization of the stamp shaft, the machine is so

The small space occupied by the machine, in proportion to the amount of work done, is a point very much in its favor. Two of the large size stamps, having a combined capacity of 240 tons a day, occupy a room only 20x40 feet, while drop stamps, having the same crushing capacity, require from two to three times as much room, and also require many more cubic feet of foundations.

A very important consideration in the working of all stamps, is that relating to the wear of the stamp shoes and dies. We are told that the practical use of the Ball stamp has demonstrated that in this respect they show a marked superiority over the ordinary drop-stamp when working upon similar ores.

All parts of the machine show careful workmanship in their construction, and where extraordinary wear is likely to take place, special materials have been used to withstand it.

These stamps are used very extensively in the copper region of Lake Superior, for crushing the copper ores found there, and of the many mines using them, the most prominent is the Calumet and Hecla mining company, which runs six heads of the Ball stamps, and crushes 800 tons of ore per day. When sending these stamps to localities with which there is no com-

munication during the winter months, it is customary to send with them a duplicate set of piston rings and sometimes an extra piston rod.

Boys are generally employed to run the stamps and men to feed the ore. When all of the conditions have been the same, the inventor informs us that the cost of stamping with the Ball stamps has been about thirty per cent. less than that of other stamps.

As a matter of interest to those who desire to know something of the details of the work done by this machine, we condense from a tabular statement, extending through the year ending December 31st, 1875, the cost of working three heads of these stamps at the Pewabic mine, Lake Superior. Number of cords of wood used in the year, 5,332½; tons of coal used, 70; cost of wood, \$20,044.47; cost of coal, \$420; cost of supplies—oil, packing, belting, etc., \$3,772.06; cost of foundry bills, \$2,021.68; cost in wages, \$19,950.37; number of days running, 281½; tons of rock crushed, 58,942; tons crushed per cord of wood, 10.84; cost of stamping and crushing one ton of rock, average, 79 cents. The highest cost was 89 cents and lowest 68 cents, leaving the 79 cents as average. These figures cover a year's work. The cost of stamping as given includes cost of fuel, lighting mills, all repairs, washing, pumping, water, used in operations, help employed in stamping and washing, and every item of expense connected with the mill.

No attempt has been made by the owners to introduce the stamp battery on this coast previous to the Centennial exhibition, their attention being given to the Michigan copper district, where they have built very extensive mills, in which all the machinery was of their invention. The award given this machine at the Centennial was "excellence of machinery and apparatus for the purpose intended; permitting its extended practical application." Mr. E. P. Ball, of Chicopee, Mass., is proprietor of the patents, but the machines are manufactured by the Holyoke Machine Co., Holyoke, Mass. A number of the machines have been long at work in the copper mines in Michigan. The amount of rock crushed by six heads of the stamps of the Calumet and Hecla company alone for the past four years was 880,920 tons, an average of 220,230 tons per year; 734.1 per day, or 122.35 tons per head per day. For the year 1874-5, the average per head per day was 133 tons. These facts, from actual experience and daily work, are of the greatest interest to our mine owners on this coast, and worthy the attention of all who are interested in economy in mine or mill operations.

Deputy Mineral Surveyors.

The Commissioner of the General Land Office has issued instructions to Surveyors General, calling their attention to the fact that Section 2,324 of the Revised Statutes of the United States authorizes the appointment only of competent surveyors. The Surveyors General are instructed that when in the discharge of their duties they become convinced that a deputy who has received an appointment is incompetent or careless in the discharge of his duties, they will promptly revoke his appointment. They must require each deputy mineral surveyor to enter into bonds, with two or more sureties, in the sum of \$10,000, for the faithful performance of his duties in the survey of mining claims under the mining statutes.

The fact of these "instructions" having been issued, would naturally lead one to suppose that the Commissioner had reason to believe that deputy surveyors who were incompetent or careless had received appointments. The order puts a "flea in the ear" of the Surveyors General, and is a mild hint for them to be more careful in their selections of deputies for the future. It is no more than right, however, that the Commissioner of the Land Office should do all he could to insure the appointment of efficient deputies, as to these deputies is given the actual practical work on which a great deal depends. If they are incompetent or careless, they can make a great deal of trouble for the future, as their surveys, when incorrect, can involve companies in litigation. Great care should be exercised in the appointment of deputy mineral land surveyors for these reasons. The authorities of the Land Office, before whom many disputes, as to boundaries, etc., come, no doubt have seen more of the evil effects of having incompetent deputies than any other persons, hence these instructions, which one would have supposed to have been well enough understood beforehand by Surveyors General. As they themselves may have been careless in their appointments, however, they are now reminded of their duties and, perhaps, delinquencies in this direction.

A HINT.—Old worn-out blankets covered with calico make very good comforters.

New Mexico.

[Written for the Press by F. M. F. CAZIN, M. E., Bernardino, New Mexico.]

Its Climate, Population, Trade, Mineral Resources, Etc.

The new State of Colorado is with its import trade dependent on the Eastern States, with the single exception of fresh fruits, which are imported from California. Its export, with no exception, goes east. In Utah Territory an inclination towards the west is visible, but can hardly be called effective. Thus the "ne plus ultra" line is reached there for San Francisco trade. Further south circumstances are more favorable to an extension of this trade further east, and the next coming years will decide whether the Rio Grande valley will trade in future times predominantly east or west. Arizona may, by the opening of the Southern Pacific railroad to the Colorado valley be considered as conquered for San Francisco, and the extension of this road to the Rio Grande before, from the north, either the Denver-Rio Grande (narrow-gauge), or the Kansas Pacific, or the Atchison, Topeka, Santa Fe would come in, would accomplish the same for New Mexico. The sympathies of the native population go all south and west, and those of the immigrant element go where their interests are best fostered. By all natural elements San Francisco and California are as able to become the place of import and manufacture for the Western half of this continent as New England is for the Eastern half, unless the anti-Chinese policy prevents the adoption of any cheap labor. But even with such policy, cheap labor may be secured in cultivating a close relation with the Mexican population of this Territory, offering a first-class element for cheap and good labor.

It remains then to be seen whether the Territory of New Mexico also deserves by its natural resources the attention of the

San Francisco Trade

And of Western railroad men. After traveling over and staying in this Territory now for 17 months, I decidedly answer the question with "yes," and the reasons therefor are: New Mexico is favored by a climate superior to any as yet known for salubrity, stock raising and agriculture, the latter in part with assistance of irrigation, which is feasible. It possesses a native population of 120,000, offering cheap labor in a natural and incontestable way. The geological formation of what part is mountainous is favorable to the production of fine and base metal, and the plains to a large area of coal. All of these minerals have been discovered to great extent in area and in quantity, but have as yet not been developed, with a very few exceptions, to any extent.

As to Climate.

The fact is well known that the elevation of the whole Territory above sea level is from 5,000 to 6,000 feet in the plains. The air is dry, curing meat in the sunlight, and mummifying bodies exposed without burial. Putrefaction is nearly impossible under the influence of air, wind and evaporation. It therefore is but natural that tubercular diseases are causing a lower rate of deaths in New Mexico (8%) than in any other State or Territory of this continent, it being 5% to 6% in the Southern States, 14% in Minnesota and 25% in New England. I may further quote an expression of R. W. Raymond with regard to the climate of New Mexico, who certainly could not be easily prejudiced, having seen so much of both the East and West of this continent. He says: "The climate of New Mexico is mild and healthy, the sky is clear as that of Italy, and the air transparent and pure. In fact the very act of breathing in this country makes existence in it a pleasure." (Report for 1871.) If for any thing as yet New Mexico is appreciated, it is its stock-raising facilities, equaling those of Southern California, so I may dispense with specifying them.

Agricultural Resources.

In this journal it may not be appropriate to enter into the details of agriculture and horticulture, but it may be stated that wheat, barley, oats and corn yield, under irrigation, as well as on the mountain slopes without irrigation, very large crops. To the better initiated it may be remarked that the Mexican corn has eighteen rows of grains to the ear, and that on land not irrigated. I measured them fifteen and sixteen inches long on an average. Underground vegetables grow to marvelous sizes in general. In the production of grapes and wine the Rio Grande valley could compete with the Los Angeles district in California, if there was not a narrow limit as yet for the sale of both. The naturalized grapes produce a heavy and aromatic wine, but as yet its manufacture is in its earliest childhood.

The Native Population.

Though comparatively numerous, is to-day (to judge by the nearly innumerable ruins of villages and towns met with wherever there is space for the plow and water for irrigation) but a small fraction of what it once was. As causes for the decrease, must be designated, first, the tyrannical treatment by the Spaniards of the Pueblo Indians; the only tribe of the red race which built towns, tilled the soil, manufactured cloth and lived in permanent communities and under statute government and law. A war of

extirpation was fought between the two races, the Spaniards and Pueblos, in the second half of the seventeenth century. A common stratagem of the Indians, favored by the natural quality of the ground, consisted in conducting the water of their springs so as to make it sink and disappear and then to cover the spring, so as to keep the Spaniards from repopulating the towns they, the Indians, had to leave. Then came, as the second cause, the immigration of Indian races of a worse class and their continual uninterrupted depredations on the inhabitants, not as yet fully exterminated, but now lessened and restricted to remote parts. As a third cause of diminution of population or of non-increase, must further be quoted the concentration of ownership of desirable lands in the hands of a small number of families—a state of things fostered considerably by the Mexican system of land grants. The "landed aristocracy" exercised a despotism over the plurality—considered as their peons—more atrocious than slavery, and only lost its worst feature during the civil war.

Up to date, the lower class has derived but little advantage from the free institutions of this country; because, for lack of knowledge, by habit, by blind devotion to the Catholic clergy, they exercise their right of voting, as they are bid to do, and if they disobey, "returning boards," on a small scale, have settled the matter ever since New Mexico became a part of the United States of North America. This brings us to the last and fourth cause of this country's stagnancy, which consists in the quality of the federal officials who have had the government of New Mexico since 1847.

The last Mexican governor, Manuel Armija, boasted openly, after Louis XIV, "L'état c'est moi" (it is me who is state and law); but in

FIG. 2. VERTICAL SECTION OF MONTEZUMA MINE, NEW MEXICO.

practice the Federal officials have put up the same rule. To judge by the numerous details told and asserted by respectable parties, and by what good evidence can be found in public records, in no country was there ever such general pilfering on the public property; such open-faced robbery on hitherto undisputed private property; such audacious perversion of right and laws; such a general whitewashing of criminals for money; such a temerity in persecuting and killing the opposition element; such a wholesale perversion of public lands into private property by falsification of records and documents—in no country but in this has such misgovernment existed with such impunity. This has only been possible, of course, by the connivance of a corrupt official element, and the former "aristocracy," mostly indifferent to the interest of the population in general; ambitious of official recognition and, with a few honorable excep-

FIG. 1. "FAULT" IN THE MONTEZUMA MINE.

tions, as corrupt in money matters as the carpet bag element.

The Approach of Railroads

Has, within the last five years, brought in white immigration, and independent of the official element and this new element is the opposition party. This white element is getting stronger every year, and the departments in Washington will soon be forced to no longer ignore the acts of officials in this far remote Territory.

But, notwithstanding this diminution, a native population of 120,000 affords all the common labor which there may be need of at \$1 per day of 10 hours, and this labor is of a good average quality. The

The Rocky Mountains Cross this Territory From north to south—the north, Colorado, and on the south Chihuahua. The San Juan country on the north, the richest of the whole (not part of Colorado alone, but with its richest parts stretching into New Mexico), and the buried wealth of Chihuahua on the south, making it hardly probable that what is between the two rich ends is alone poor. It is not poor by any means. Wherever attempts at prospecting have been made rich discoveries have resulted. I know villages which, for all that is known, for centuries lived on the gold that was washed within the limits of the village with the water of a spring not filling a one-inch pipe, or with the melted snow in winter time. But there are also large areas showing gold, but not worked at any time yet, of which, at the present moment, the Tierrillo

district is attracting attention and immigration; and others again, where the immigration element has taken hold with greater energy, but which, in order to arrive at the stage of development and production require this element to be strengthened by outside assistance. As one, and I may say the most prominent case of this kind, I may be permitted to describe the most northern but real new Mexican mining district, called the

Bald Mountain Gold Mines.

And its most prominent, because best developed mine, the Montezuma gold and silver mine. Leaving the Union Pacific Railroad at Cheyenne, and following the railroad southward by Denver and Pueblo, the last station is reached at El Moro, and four miles drive brings you to Trinidad, the most southern town of Colorado, situated on the northern edge of the New Mexican coal field, producing a bituminous coal and manufacturing coke. From Trinidad, driving through Batton pass, on the divide of which an old pioneer, Ben Wooden, keeps the tollgate, and now enjoys an idle way of life, (with a wife and pretty children, altogether with a number of stout and sturdy elder sons and daughters) we arrive on the east slope of that part of the Rocky mountains called "Spanish Range," and within sixty miles we will reach the town of Cimarron, the last one south showing Anglo Saxon, or, I might say, civilized origin, because all what lays further south consist of "adobe" (mud brick) construction. Cimarron has a history of its own, because it is the

Center of the Maxwell Grant,

Begotten in fraud and baptized in fraud, and now in consequence of this, all at the same time, honestly recognized by the United States, and honestly in a state of bankruptcy. There are

over the divide to Elizabethtown and the Moreno gold diggings on the west slope of Bald mountain. For four miles up Ute creek then we meet gulch diggings in full activity, but in small claims and without organization, and in constant war for the use of the water of Ute creek. At the head of the gulch is the

Montezuma Mine.

As above mentioned this mine has quite a history, and had it fallen into the hands of American moneyed men instead of being worked by English and Dutch adventurers on a pretended title, this mine would to-day be one of the most prominent producing gold and silver mines on the North American continent. The title of the mine extends over 1,500 feet, of which only the western part, about 500 feet, have been opened. The other 1,000 feet stretch down the mountain slope and can be worked by tunnel as well as the upper part.

A vertical section on the plane of the lode, given herewith, shows the exploration work done on the mine, but gives only an imperfect idea of the successive development. The adit level was run on a parallel spur for a distance of 310 feet, although the lode had been discovered and laid open by the discovery shaft, and the lode has then been followed by level to the surface, 253 feet from the joining point.

At a distance of 401 feet from the mouth of adit level there is a fault five feet wide, throwing the lode 42 feet off its course towards the north, after which the lode continues its true course, which is nearly east and west (8½° north of east by true meridian, or 21½° by magnetic meridian). The slate at the mouth of the tunnel is a large fault (slip) in the granite itself, visible even by the surface contour of the mountain, and has been verified by the Aztec mine sinking into the slate, and as yet not penetrating, as shown in Fig. 1. Fig. 2 is the vertical section of the mine. In this a shows the discovery shaft; b, mouth of tunnel No. 1; c, mouth of tunnel No. 2; d and e, shafts; f, winze; g, drift; h, slate; i, granite walls; r, fault through the lode, 42 feet out of course; l, slopes.

The crevice is on the average two feet wide in the workings, but shows widening out in stretch and depth at numerous places. The average assay will not prove, in all probability, above \$75, but not less, (although soon after the first discovery the Commissioner of the General Land Office, by his report for 1868, received from this mine a specimen showing fibers of pure gold more than two inches long, and assaying \$19,000 to the ton,) although the ore at present worked in arastras paid higher average assays. At the lower edge of the property a permanent creek flows, and the mine has a special water right and mill site; also a privilege for timber and fuel on a large forest. It is timbered and preserved in a splendid way, and will not occasion any considerable outlay to start operations on a large scale; in fact the mine is waiting simply for somebody to take hold of it, and only a portion of the previous outlay on it by the English is asked as purchase price.

Although New Mexico has no mines as yet in the same state of development as the Montezuma, it has many discoveries deserving the attention of men experienced in mining and reduction, and provided with means to see an enterprise through to success. The owners of the Montezuma, as well as of all other discoveries in New Mexico, have no such experience and no such means.

BLOWING UP A MONITOR.—The following details are received of the destruction of a Turkish monitor by torpedoes: "Two young Russian engineer officers attempted to reach the monitor early in the evening with torpedoes, but were discovered and driven back by a heavy fire. At three o'clock in the morning they returned in two skiffs, carrying a chain of small torpedoes filled with dynamite. No lookout being kept aboard the monitor, they securely lodged the chain across her bows. On their return they discharged the whole series of torpedoes by means of an electric battery, and the vessel immediately disappeared." Another account says: "It was one of the most daring deeds ever recorded. Small detachments of Russian soldiers left the northern shore of the Danube in a number of small boats. The night being very dark, they managed to surround the monitor before being discovered. When finally observed by sentinels on board, they were challenged. The Major replied, in Turkish, 'friends.' Not satisfied, they commenced firing in the direction of Matchin, not knowing where the boats came from. During the fight several Russian soldiers plunged into the water, swam silently to the vessel and placed a torpedo in close contact with her bottom. After it had been securely fastened the men returned to the neighboring shore. The monitor was blown into the air and all on board perished."

A WOMAN'S GENEROSITY.—The stream of Mrs. A. T. Stewart's benefactions, says the *Church Union*, instead of ceasing to flow, goes onward, and with increasing volume. She has made donations to fifty-two of our local charities, ranging from \$500 to \$2,500, and making an aggregate of \$74,500, and the intimation comes from Judge Hilton that other charitable institutions, if found deserving, will be made the recipients of her bounty. Since the death of her husband Mrs. Stewart's donations—those of which the public have been informed—have reached an aggregate of about \$400,000.

The road from the town of Cimarron leads to the Bald Mountain gold mines, west, up Ute Creek

Excavating Machinery.

About a month ago we gave an illustration of an excavating machine which we saw at work in Oakland. We pursue the subject on this page by presenting a side view of another form of excavator, in which the earth is emptied from the buckets of the elevating wheel upon a draper running transversely, instead of being discharged into an earth-box, as in the one shown a month ago.

The machine is one that was built for an irrigation company in the interior, and is provided with draper attachments that will enable it to cut a canal from nine to 24 feet in width, and any depth from three inches up to six feet. By working the earth twice over, it will cut a canal 48 feet wide; and by working it three times, it would make a canal 72 feet wide; though for canals of that width a larger machine would be more economical. The machine requires four horses and one man to operate it. A plow 10 inches wide and running from two to three inches deep is used. The following is a concise and accurate description of the excavator, and if read with reference to the cut will be easily understood. The elevating wheel and the other hind wheel are each six feet in diameter. The forward or caster wheel is two feet six inches in diameter. The tire of the elevating wheel is of steel, five-sixteenths of an inch thick by 12 inches wide. Bolted to each of the spokes is a blade of iron eight by 12 inches, which form a series of buckets completely around the wheel on the inside of the tire. The spokes of the wheel are set even with one side of the tire, so that a draper can be projected far enough under the buckets to receive their contents. The buckets, it will be observed, are set obliquely across the tire, so that they will hold the earth till it gets near the top of the wheel. A segmental shield also assists in preventing the discharge of the dirt till it arrives at the apron, or draper.

The plow which throws the earth into the elevating wheel is directly in line behind the "rear" horse, and is so located that it will plow close up to a vertical wall, thus enabling the machine, when used for canals, to make the banks perpendicular, if required, or slope them at any angle. The plow can be set to run at any desired depth, and is easily raised by the handle seen at the left of the driver.

The side-pieces of the carrier frame are iron pipes, the outer half sliding into the other portion like a telescope; there are also screws at the outer end by which the route carrier roller

can be moved out and in, to compensate for the expansion or contraction of the draper. The draper is 30 inches wide and is made of 12-0 duck, the same as that used for making hydraulic hose. It is almost one-eighth of an inch thick. A bevel wheel 24 inches in diameter is keyed on the hub of the elevating wheel, and turns a short shaft leading to the inner draper roller, which being thus caused to revolve, gives motion to the draper or carrier. The draper runs once and a quarter as fast as the horses walk. The picture shows the machine as seen from behind. It is represented to be making a cut or canal through the top of a hill to show the form of the embankments, etc.

The draper is shown carrying the earth somewhat up hill, but it can be lowered in a moment so that the dirt runs down hill, thus assisting to run the draper instead of being carried by it. It will seldom be necessary to raise the draper higher than to a horizontal position, unless for loading carts or wagons.

The driver has little more to do than to drive his team. A little lever is touched, and the plow drops down to its work, requiring no further attention. When it is necessary to stop earth from going into the wheel, raise the plow, and the thing goes along as quietly as a wagon.

Any ordinary man that can drive a reaper will have no trouble with it, for it has no more machinery than the simplest mower. The duties of the operator consist of oiling the bearings, seeing that the draper is kept at the required tension, and that his plow is sharp.

The weight of this machine is nearly 2,500 pounds, depending somewhat on the length of draper used, as it is necessary to carry a little weight on one side of the machine to counter-balance the weight of the draper, and, of course, the longer the draper the greater the weight required. The two hind wheels are four feet six inches apart from center to center.

This machine, like the one we illustrated before, is manufactured at San Leandro, Alameda

county, and the city agency is at the headquarters of the Price Press Company, with Baker & Hamilton, No. 17 Front street.

New Section of Central Pacific Railroad.

The new section of the Central Pacific Railroad, now in course of construction from Oakland by way of the straits of Carquinez to a point between Ellis and Bantas, will be of vast importance in facilitating and reducing the expenses of operation. Practical experience in railroading has demonstrated that it is cheaper, time and cost considered, for a locomotive and train to run three or four miles around than to go half a mile over a grade in excess of 20 feet to the mile. For such reason the great Southern Continental and Mexican railroad traffic which will come and go through the San Joaquin valley, in addition to that of the local section, is to be taken around on the tide water grade line, thereby avoiding the numerous sharp curves and heavy grades of the Livermore hills. The new line, says the Contra Costa Gazette, is slightly longer than that over the Livermore hills, but will be an hour or more shorter in time of travel and not half so expensive in cost of motive power and wear of rolling stock and rails. For the same reason that the traffic of the south is to be provided with a tide water grade line on this side, that of the Sacramento valley and Oregon is to be saved the climb of 90 feet grades of the Suscol hills, over which the Vallejo road is laid. This line will strike the Straits of Carquinez at Benicia, and cross the water on powerful train ferry boats, and between Martinez and Oakland the road on this side will be laid with a double track of the heaviest steel rails, calculated to carry the combined traffic of the North and South that will converge on it,

Supreme Court Decision on the Tax on Mines.

The Supreme Court of the United States has rendered a decision in the case of Charles Forbes, appellant, vs. Thomas Gracey, Consolidated Virginia mining company, J. W. Mackay and J. G. Fair. This was an appeal from the Circuit Court of the United States for the district of Nevada. Mr. Justice Miller delivered the opinion of the Court; Justice Field being disqualified, took no part in the discussion. The statement of the case is that this was a suit brought by appellant to enjoin the collector of taxes for Storey county, Nevada, from collecting a tax imposed by the law of that State upon the property of the Consolidated Virginia mining company, the appellant being a stockholder in the company and an alien subject of the Queen of Great Britain. The tax is by the State statute imposed upon the proceeds of the mine worked by the corporation, and is resisted on the ground that title to the land from which the mineral is taken is in the United States, and is not for that reason liable to State taxation.

Following is the synopsis: Congress has, by statutes and tacit consent, permitted individuals and corporations to dig out and convert to their own use the ores containing the precious metals found in the lands belonging to the Government, without exacting any compensation for those ores, and without requiring the miner to buy or pay for the land. It has gone further, and recognized the possessory rights of these miners as ascertained among themselves by the rules which have become the laws of the mining districts as regards mining claims. But in doing this it has not parted with the title to

plow and work the mine under existing laws and regulations.

In the former case, the United States has no interest to be protected, and the State is at liberty to declare and enforce such a lien for her taxes. In the latter, also, such right as the mining laws allow and as Congress concedes to develop and work the mines, is property in the miner and property of great value. That it is so is shown most clearly by the conduct of the mining corporation in whose interest this suit is brought, which for the purpose of evading this tax, permits its investment in this mine, said to be worth from fifty to a hundred millions of dollars, to rest on this claim, this mere possessory right, when it could, at a ridiculously small sum, compared to the value of the mines, obtain the Government's title to the entire land, soil, mineral and all. These claims are the subject of bargain and sale, and constitute very largely the wealth of the Pacific coast States. They are property in the fullest sense of the word, and their ownership, transfer, and use are governed by laws and are recognized by the States and Federal Government. This claim may be sold, transferred mortgaged, inherited, without infringing the title of the United States. Why may it not also be made subject to a lien for taxes, and be sold to enforce the lien? We see nothing in principle or in any interest which the United States has in the land to prevent it.

Decree of the Circuit Court dismissing the bill of appellant is affirmed.

Soldiers Additional Homestead Entries.

The Commissioner of the General Land Office has prepared, and will issue as soon as they can be printed, an important circular of instructions regarding soldiers' additional homesteads. These instructions will give effect to Secretary Chandler's decisions of March last permitting entries to be made in the following cases:

First.—those presented prior to the order of March 20th, 1876, suspending all entries, and rejected for reasons insufficient in law to bar their reception, but kept alive by appeal, which by such rejection were postponed beyond the date of the order, and so lost. These may be admitted without further formality when again presented at the district office, after the settlement of the question upon which they were originally refused; but the right of the applicant to make entry to be fully inquired into in the final adjudication in Washington.

Second.—Those actually in the hands of agents or attorneys on May 22d, 1876, and still remaining in their hands, but these claims must be forwarded here for consideration, and shall not be accepted by Registers and Receivers for location until returned to the agent with the Department's certificate of entire validity and sufficiency.

The third and last class that will hereafter be recognized, embraces those rights yet remaining in the hands of parties originally interested, which have never been presented for satisfaction, or made the subject of transfer or agency.

Commissioner Williamson requires to secure these rights that a full recital of military service shall be presented to the General Land Office, with the proof of identity of the party making the claim, and detailed reference to his original homestead entry, with name of local land office, date and number of entry, and description of land. He must also file a sworn statement setting forth the facts indicative of his right to take the entry, and declaring that he has not in any manner exercised his right, either by previous entry or application, or by sale, transfer or power of attorney, but that the same remains in him unimpaired. He must also declare under oath that he has fully complied with the homestead law regarding residence upon and cultivation and improvement of his original homestead entry; and he should further recite whether or not he has proved up his claim and received a patent. When these papers are filed and examined, they will, if found satisfactory, be returned with a certificate attached, recognizing the right of the party to make an additional entry under the law, and when properly presented at any land office, either by the party himself, or his agent or attorney, will be accepted by the Register or Receiver and forwarded with the entry papers to Washington in the usual manner.

It is confidently anticipated that these instructions will have the effect of calling in all outstanding rights, and speedily closing up this whole business of additional homestead entries, without leaving room for further frauds or serious trouble.

THE PRICE EXCAVATOR WITH DRAPER.

making it the grand trunk of the entire continental and State system of the Central Pacific company, and a section on which in the not very remote future there will be more traffic than on any other in America.

There are some 2,000 men employed on the construction work of the road, and the number is to be largely increased soon, it being the announced purpose of the company to have its trains running over it in August next. From the junction at the eastern end, to Antioch, the grade is already completed, and the track is being laid on it at the rate of about a mile a day. The grading from Antioch to Martinez involves but little heavy work, but from Martinez to Point Conchal it is heavy cutting and filling all the way, besides the work of driving the two tunnels at the foot of the straits, one of which is 700 and the other 400 feet in length. These tunnels are to be 28 feet wide and 32 in height. The longer of the two, near the residence of Mr. Patrick Torney, is nearly completed, in quite firm rock; the other, through the point of a hill about three-quarters of a mile east of the first, will require timbering all the way through, it is thought, as the formation cannot be trusted for self-support. Most of the grading force is now employed on the tunnels and the points along the Pinole shore, the grade for single track having been already completed through Conchal ridge and the rails so far laid from Oakland. The grading for double track is done as the work proceeds where the material to be moved is sufficient and is to be placed near by; but most of the double track grading, where the earth is to be moved any considerable distance, is left to be done when the single track is laid.

It is said that several large grading parties will be put on along the shore of the straits, between the tunnels and Martinez, this week and next; but the track coming from the San Joaquin will probably reach Martinez before the grading below is ready for it.

the land, except in cases where the land has been sold. If the tax of the State is levied on this property right of the United States, we are bound to hold that it is void. If it is levied on property of the miner, and may be collected without embarrassing the title of the United States to its property, then there is no ground for interference in its collection.

2. It is the ore after it has been separated from the bed in which it is found, and its proceeds and products, which are taxed, and not the ore or mineral in the earth. When this ore becomes detached from the soil in which it is imbedded it becomes personal property, the ownership of which is in the man whose labor, capital and skill has discovered and developed the mine and extracted the ore. It is then free from any lien, claim, or title of the United States, and is rightfully subject to taxation by the State as any other personal property is.

3. In regard to the taxing of this personal property, and the mode of collecting it by sale, it does not appear that the United States has any interest in the tax, or in the sale of the property taxed. The law of Nevada which makes this tax "a lien on the mines or mining claims from which the ores or minerals bearing gold or silver are extracted for reduction," does not interfere with the right of property of the Government in the lands in which the mineral remains are extracted.

4. The words "mines or mining claims" distinguish between the cases in which the miner is the owner of the soil and therefore has perfect title to the mine, and those in which the miner does not have title to the soil, but works the mine under what is well known in the mining districts and what is recognized by the act of Congress as a mining claim. In the first case, the statute makes the tax a lien on the mine, because the title to the mine is in the person who owes and should pay the tax. In the other, the tax is a lien only on the claim of the miner; that is on his possessory right to ex-

An English Straw-Burning Engine.

As the threshing is near at hand, notes of threshing machinery are timely. We have formerly given illustrations of engines made by Pacific coast and other American inventors, and to make information on the subject of threshing engines more complete, we present on this page an engraving showing an English machine, which has been introduced on this coast, and thus demands attention. The illustration gives a good idea of the engine, and it is plain that its general characteristics are strength and symmetry of form and design. It is from the manufactory of Ransomes, Sims & Head, of Ipswich, England, and this firm is represented on this coast by Mr. E. L. Ransome, 10 Bush street, San Francisco.

To describe the engine which our illustration shows, we shall quote from an address which Mr. John Head, C. E., read before the British Associated Institute of Civil Engineers. Mr. Head is one of the inventors of the engine, and his claims for it may thus be learned:

"The expansion engine here illustrated are manufactured from six to ten-horse power with single cylinders, and from ten to 30-horse power with double cylinders. The proportion of the steam generating power of the boiler to the cubic quantity of steam required in the cylinder to develop the maximum power at the normal speed has been carefully considered; and from a variety of experiments it has been found that the consumption of fuel in these boilers does not exceed more than about four pounds of coal per effective horse power per hour.

In designing the boilers the main object has been to obtain the greatest amount of evaporation from a boiler of moderate dimensions, and about eight pounds of water may be reckoned as the average evaporation by one pound of coal in the boiler illustrated on this page. The usual proportion of heating surface is, 15 square feet of tube surface, .60 to .75 of grate surface and 2.75 to three square feet of fire-box heating surface, per nominal horse power. These boilers are manufactured of the best brands of English plates, and the riveting is almost entirely performed by hydraulic machinery, which does not destroy the fiber of the iron in the rivets so much as hand riveting. The average working pressure of steam in these boilers is from 80 to 90 pounds per square inch, and they are tested with hydraulic pressure up to 160 pounds per square inch. Both the barrel and the outer fire-box are covered with felt lagging through out, which prevents radiation and tends greatly to economize fuel when the engine is at work in the open air during cold or damp weather.

The engine proper is placed on the top of the boiler. The cylinder is jacketed throughout, and the valve chest is accessible for repairs, not only from the front but from the top, which enables the slide face to be filed and scraped when worn without taking the cylinder off the boiler.

The crank shaft is carried on two cast iron brackets, firmly bolted on to the cylindrical part of the boiler.

These brackets are stayed to the cylinder by means of two strong wrought iron stays, one end of which is bolted to the top of each bracket, which is elongated so as to make it the same height as the cylinder, and the other ends are attached to strong lugs cast on the cylinder. These stay rods—which are screwed up when the boiler is hot, so as to compensate for the expansion—bind the whole of the working parts of the engine most firmly together, and prevent any of the vibration which is so often felt in portable engines when they are doing the maximum amount of duty.

In the general arrangement, the principle of moderately high piston speed, with a medium diameter of fly-wheel, has been preferred to a long stroke and slow speed with a larger fly-wheel. The reason why this system is adopted is, that the motion of the engine at a high speed is more uniform and is not liable to be so easily affected by the sudden shocks to which all small engines are exposed. The average piston speed is from 280 to 300 feet per minute; the number of the revolutions of the fly-wheel from 140 to 150 per minute; and the speed of the periphery of the fly-wheel varies from about 2,000 to 2,500 feet per minute, according to the size of the engine. All the bearings of the crank shaft, connecting rod and piston rods, are large and of great length, thereby distributing the strain over a larger surface than is theoretically required.

The apparatus for feeding the straw, reeds and other fuel into the fire-box, as shown in the cut, consists of two toothed rollers placed at a minimum distance of about one-fourth of an inch apart, and capable of rising so that the distance between them can be increased to one and one-fourth inches. The under roller is set in motion by means of a strap from the crank shaft of the engine, and makes about 45 revolutions per minute. The upper roller moves at the same speed, and is connected with the under one by means of long-toothed wheels. The rollers are

carried on a cast iron frame, to the front of which is attached a trough for holding the supply of vegetable fuel to be fed into the furnace. The rectangular space between the rollers, which serves as a passage for the fuel into the boiler, is placed from four to five inches above the fire bars, this distance having been found by experience to give the best results, as by injecting the fuel at this point the fresh substance forces its way into the center of the burning mass inside the fire-box, and ignites more quickly than when it falls on to the top of the fire. The theory of the invention is, that by means of a continuous mechanical feed, the fuel can be forced into the furnace in a thin stream in the form of a fan, and the fresh fuel is practically held in suspension for a short time, allowing the separate stalks to become immersed in the flames, and the long pieces of straw, reeds or brushwood to have the effect of stirring up the half-burnt material in the furnace, thus keeping the whole in motion.

Reception of the Microscopical Society.

The fifth annual reception of the San Francisco Microscopical Society was held on Thursday evening, May 24th, at Mercantile Library Hall, and was well attended by the invited guests of the members. A programme was arranged of those objects for each of the exhib-

from his marine aquarium as *Parypha crocea*, *Laomedea amphora* and *Laguncular repens*.

Mr. H. K. Moore favored those present with some of the most interesting forms of diatoms, and also spicules of gorgonia, displayed on a dark field.

Mr. C. Mason Kinne selected for his exhibit the respiratory organs of insects, plants and shell-fish, for the purpose of comparing the methods in which different orders managed to breathe.

Mr. W. F. Meyers displayed several whole insects, the one attracting the most personal interest being a flea. Mr. G. H. Williams exhibited mounted proboscis of blow-fly, and other parts of the same insect. Dr. S. M. Mouser, in his exhibition of the circulation of blood in the mesentery of a frog, united with the natural showing of the red and white corpuscles, attracted his share of attention. Dr. S. W. Dennis, in the sulci of several human teeth, showed plainly the normal condition, and incipient and advanced caries of those organs. Dr. E. H. Woolsey gave an idea of the structure of the human skin, and also how the fungus of a skin disease played havoc with the tissues. Dr. J. W. Winter had something to say of odontology, with interglobular spaces, sulci and secondary dentine shown in sections of teeth prepared by himself. Rev. J. H. Wythe, M. D., indulged in a fine showing of minute anatomy, and drew upon the brain, spinal cord and nerves for sub-

ENGLISH PORTABLE STRAW BURNING THRESHING ENGINE.

itors to present, most of the slides being selected from specialties cultivated by the members. Twenty-two fine microscopes were placed on the tables about the room, most of them first-class instruments, and as the guests moved about from one table to the other the gentlemen in charge explained the objects exhibited.

The President of the Society, Prof. Wm. Ashburner, was at the first table, with vegetable structure, of which, perhaps, the most interesting was a leaf of the insectivorous plant known as *Drosera rotundifolia*, with its tentacles and other parts. Darwin's exhaustive researches into the habits of this plant have made it world-wide, and it was a fitting introduction to the vegetable tissues shown by Mr. C. W. Banks, which had been double stained for the purpose of better defining their structure. Other objects of a similar nature were exhibited by this gentleman, as opportunity offered, though most of the members found that their three objects well explained, were all they could get through with to advantage.

Vegetable tissues—polarized, formed a beautiful series of objects, shown by Mr. X. Y. Clark, and the starch grains, redwood bark and raphides took a new interest in the minds of all, as the polariscope added its efforts to the natural beauty of the most useful kingdom in nature, the vegetable. Mr. E. J. Wickson continued in vegetable structures, showing the relative position of the exogens and endogens, and supplemented by the anatomy of a leaf. The pollen of rose and hairs of *Deutzia scabra*, by Mr. G. L. Murdock, and varieties of the cryptogamia, in the way of ferns, fungi and algae, by Mr. J. Z. Davis, brought us in natural sequence to some of the lower living forms, which were finely shown by Henry C. Hyde, Esq. The protococcus and diatoms, which were motile, were almost animal in their popular characteristics of locomotion.

Mr. J. A. Langstroth also favored the audience with living objects, in the way of such animals

jects. Mr. John Hewston, Jr. had, perhaps, the most beautiful exhibit of the evening, though not tending so much toward the general diffusion of knowledge as some of the others. Polarized light, when applied to such chemicals as salicine, resucine and platino-cyanide of magnesium, cannot fail to draw out the enconiums of all lovers of the beautiful. Mr. Melville Attwood, not being able to attend, Mr. W. H. Lent exhibited Mr. Attwood's slides of rock sections from the Comstock lode, as well as his own marine objects. Mr. J. R. Scupham, in minerals, had some crystals of native gold and silver, as well as copper. Dr. A. Mead Edwards told something about the formation of coal, and showed a series of objects from carboniferous deposits, embracing Newcastle coals, fossil pines, and recent pine wood.

NO UNDERGROUND GAS.—A dispatch from Washington says: An official letter just received from a high Government officer on the Pacific coast asserts unreservedly and earnestly that constantly accumulating deleterious gases in the Comstock mines generated from the hot water found at present at the great depths of working, bid fair soon to compel the abandonment of work on the lode, unless relieved by a speedy connection with the Sutro tunnel. This statement was so impressive that Mint Director Linderman sought an interview with J. W. Mackay on the subject, but failed to meet him, as Mackay had already left for Europe, remaining only one night here. Another dispatch referring to the above says: The reported letter from a Government official on the Pacific coast about the existence of dangerous gases in the Comstock mines has no foundation in fact. W. H. Patton, Assistant Superintendent of the bonanza mines, says there are no gases of any description generated by the hot water in the mines; the present system of ventilation by means of drifts and winzes works satisfactorily.

An Accident Fund for Railroad Hands.

On the 7th of March last the following circular, addressed to the Division Masters of the Central Pacific Railroad Company, and signed by A. N. Towne, General Superintendent, was issued from the main office of the Central Pacific Railroad Company in this city:

"I have given the subject of a Mutual Aid Society much thought and consideration, and I am satisfied that great benefits would grow out of a society of this kind. Through our assistance it could be formed by all classes of train, engine and yard men in the service. I would suggest that each member should contribute a given amount—say one dollar—to the family, or nearest relative, in case of the decease of any member by injury while in the discharge of his duty. The same amount to be contributed to the person directly when, in case of accident, it may become necessary to amputate a limb—say an arm, leg, hand or foot. The collection of contributions and the disbursements could be made through the officers of the company, thereby saving the members any expense that would naturally attend an individual organization with salaried officers, rent, etc. I am so much impressed with the advantages the unfortunate would derive from such a plan as this, that I desire you to confer by letter, or, preferably, in person, with all the train and yard men in your division upon the subject, noting any suggestions or objections they may have to offer. I would like you to send me a list of all your men, giving in ruled columns the names and occupations of those who favor such a plan and those who do not. Should it meet with general favor, I will draw up a plan for an organization with rules and by-laws, and submit it to you and through you to the men. I will write A. J. Stevens, G. M. M., and ask him to ascertain if the engine men would not be glad to come into the arrangement. Any suggestions you may have to make I will be pleased to receive and consider."

In compliance with the request or order contained in the above circular, the Division Masters forwarded the list of men under them, noting opposite their names whether they were in favor of the proposed organization or opposed to it. From the General Superintendent of the company a reporter learned that fully 95 per cent. of the train and yard hands had signified their willingness to contribute to a mutual aid fund such as designated in the circular. Subsequently another circular was issued defining more accurately the scope of the society and suggesting the mode of collecting dues, which was to be accomplished through the intervention of the company's paymaster. In this second circular the company agreed to pay from its treasury, in each and every instance in which an employee was entitled to the benefits of the society as set forth in the circular, the sum of \$100.

It was asserted after the issuance of this second circular that the C. P. R. Co. had an ulterior object in view in starting the Mutual Aid Society, and that through its workings they expected to escape the necessity of paying damages in case of injury to, or the loss of life of an employee while in their service. The proposition or agreement of the company to pay \$100 in all cases in which members of the society would be entitled, to its benefits, it is claimed by some,

would by the statutes of this State annul the right of a disabled man to sue in the court for damages, and would debar his family from going into court to recover anything in case of his being killed. It was also stated that employees of the company had been advised to sign the roll under penalty of dismissal in case of refusal. The officials of the company deny that there was any coercion used, or that any is contemplated, and Mr. Towne, with whom the proposition originated, states that if the men have any fear of the gift of \$100 from the company affecting their legal rights, the obnoxious offer will be withdrawn, as it was simply made as a benevolent offer. If the society were formed and all the train and yard men joined it, the sum to be paid to any one entitled to its benefits would be nearly \$2,000. The proposed society is not an original idea, there being several other railroads whose train employees have organized for mutual benefit, being prompted thereto in a great measure by the fact that all insurance companies regard all risks of that nature as extra hazardous.

HARD times in Russia. In St. Petersburg and vicinity, 90,000 artisans are destitute; at Moscow, 40,000. The distress among the lower classes is increasing, apparently. The commercial crisis, numerous failures of banks and mercantile houses, the closing of factories, the discharge of a multitude of clerks, and a recent inundation, which destroyed whole villages, have done the work.

THE engineers on the Lehigh Valley railroad held a large meeting on the 27th ult. at Phillipsburg. The proceedings were not public, but it is apparent that there will be a strike, if one has not already been determined upon. It is understood that the company, anticipating trouble, are making arrangements to meet it and to prevent interference with the running of trains.

GEO. W. PRESCOTT.

IRVING M. SCOTT.

H. T. SCOTT.

Prescott, Scott & Company, UNION IRON WORKS,

SAN FRANCISCO, CALIFORNIA.

Builders of the Principal Reduction Works and Mining Machinery throughout the States of California, Nevada, Utah and Arizona.

Mining, Hoisting, Pumping, Milling and Compressed Air Machinery Made a Specialty in all its Parts.

UNDERGROUND WORK FOR USE OF STEAM OR COMPRESSED AIR.

Baby Hoists—Baby Hoists of two sizes, constructed to pass through Drifts and Tunnels and handle timbers or rock.

No. 1, Direct Acting, Cylinders 4 in. x 10 in. Drum 6 in. diameter.

No. 2, Geared, four to one, Cylinders 8 in. x 12 in. Drum 6 in. diameter.

Baby Fans—Baby Fan Engines, with fans, designed with adjusting screw, to set same in any drift or tunnel.

Underground Pumps—Compound Double Plunger Pumps for sinking or Drift uses.

Drills—Rock Drills, for sinking, drifting and stoping.

Air Compressors—Air Compressors, of the best design and work, of six different sizes, suitable to run one or more Drills and supply Air to Baby Hoists, Baby Fans, Underground Pumps, Drills, Etc.

Hoisting—Hoisting Engines, Single or Double Geared, Direct Acting either Vertical or Horizontal, Condensing or Non-condensing of all designs and sizes from 4 in. diameter and 10 in. stroke up to 30 in. diameter and 10 ft. stroke for either flat or round ropes.

Pumping—Pumping Engines, Single or Double Geared, Direct Acting, either Horizontal, Inclined or Vertical, Compound and Condensing with Variable Cut-off, or Davy's differential Valve Motion of all sizes, from 18 in. diameter of Cylinder up to 120 in. diameter of Cylinder.

SILVER MILL, PRESCOTT, SCOTT & CO., MAKERS.

Mills—Mills of all sizes, for Gold, wet crushing, with or without concentration. For Silver, wet crushing, Pan Process. For Silver, dry crushing, Pan Process. For Silver, dry crushing with Roasting, Chloridizing and Pan Process.

Blake's Rock Breakers, in use everywhere.

Pacific Ore Feeders, cheapest and best in use. Pans, Settlers, Agitators, Tailing Pans, Safety Top Strainers, Retorts, Bullion Molds, Melting Furnaces, Assay Fittings, Boss' Quick-silver System, complete.

Baby Hoists and Fan Engines—In use at Consolidated Virginia, California, Gould & Curry, Hale & Norcross, Imperial, Justice, Overman and Caledonia.

Compressors—In use at Utah, Sierra Nevada, Consolidated Virginia, California, Gould & Curry, Savage, Hale & Norcross, Imperial, Justice, Baltimore Consolidated, Virginia Water Works, Grass Valley, Soulsby's Mine.

Hoisting Engines—In use at Sierra Nevada, Ophir, Consolidated Virginia, California, Gould & Curry, Savage, Hale & Norcross, Raymond & Ely, Belcher, Caledonia, Meadow Valley, Justice, Baltimore Consolidated, Rock Island, Florida, Grand Prize, New Coso.

Pumping Engines—In use at Utah, Raymond & Ely, California, Florida, Gould & Curry, Hale & Norcross, Overman, Lady Washington, Baltimore Consolidated, Rock Island, Combination Shaft.

MILLS.—The California Mill, Virginia City; the Consolidated Mill, Virginia City; the Meadow Valley Mill, Pioche; the Raymond & Ely Mill, Pioche; the Ontario Mill, Salt Lake; the Sumner Mill, Kernville; the Northern Belle Mills, Belleville; the Keystone Mill, Amador; the Tehama Mill, Cherry Creek; the Leopard Mill, Cornucopia; the Atwood Mill, Mineral Hill; the Manhattan Mill, Austin; the Surprise Valley Mill, Panamint; the Grand Prize Mill, Tuscarora; the Vulture Mill, Arizona; the Signal Mill, Arizona; the Silver Glance Mill, Arizona. The foregoing list comprises only a few of the places where machines of our manufacture are in use throughout the above named States.

Winchester Repeating Rifle.

MODEL 1873.

One-third size by Dr. E. H. Rardes.

The Strength of All its Parts,

The Simplicity of its Construction,

The Rapidity of its Fire,

The Power and Accuracy of its Discharge,

The Impossibility of Accident in Loading,

Commend it to the attention of all who use a Rifle, either for Hunting Defense, or Target Shooting.

The San Francisco Agency is now fully supplied with all the various kinds and styles of Arms manufactured by the Winchester Repeating Arms Company, to wit:

Round barrels, plain and set, 24 inch—blued. Octagon barrel, plain, 24 inch—blued. Octagon barrel, set, 24, 26, 28, 30 inch—blued. Octagon barrel, set extra heavy, 24, 26, 28, 30 inch—blued. Octagon barrel, set, 24, 26, 28, 30—extra finished, case hardened and check stocks. Octagon barrel, set extra heavy, 24, 26, 28, 30 inch—extra finished—C. H. & C. S. Octagon barrel, set, 24, 26, 28, 30 inch—beautifully finished—C. H. & C. S., known as "One-of-One-Thousand." Octagon barrel, set, gold, silver and nickel plated and engraved. Carbines blued, also gold, silver and nickel plated. Military rifle muskets, model 1873. Rifles, muskets and carbines, model 1866. RELOADING TOOLS, PRIMERS AND PARTS OF ARMS.

A heavy stock of Cartridges Manufactured by the W. R. A. Co., for all kinds of Rifles and Pistols, constantly on hand and warranted the best in the market.

JOHN SKINKER, No. 115 Pine Street, San Francisco,
SOLE AGENT FOR THE PACIFIC COAST.

ASBESTOS COATING

For Steam Boilers, Pipes, etc. Best non-conductor of heat in use. It effects a LARGE SAVING OF FUEL, LASTS AS LONG AS THE IRON to which it is applied, and is reasonable in cost.

Ours are the Only Patents for Boiler Covering that have ever been Established by the Courts.

UNITED STATES AND FOREIGN

SALAMANDER FELTING COMPANY.

Pacific Branch:--SEWARD COLE, Manager.

OFFICE, 317 CALIFORNIA STREET—FACTORY, BERRY STREET, Between 4th and 5th—P. O. Box 607, Virginia City, Nevada.

ASBESTOS COATING,

For Steam Boilers, Pipes, Etc. The Best Non-Conductor in Use.

SAVES TEN TO THIRTY PER CENT. IN FUEL.

“SALAMANDER FELTING.”

Our Patents Especially Embrace the use of ASBESTOS, LIME and PAPER-PULP for Boiler Covering.

The Material is Applied (in a plastic form), in three coats, each one-half inch in thickness.

The “First Coat,” which protects the outer coatings from the severe heat of the surface covered, is composed principally of ASBESTOS and lime-putty, and is strictly fire-proof and indestructible.

The “Second” and “Finishing” coats are composed largely of “paper-pulp,” which in combination with other light non-conductors of heat, forms a material that will never crumble or crack off, and which is susceptible of a fine enamel-like finish.

Send for circulars containing testimonials from well known authorities in the East, and on this Slope.

Each Barrel of Salamander Felting sold by us will bear our Trade Mark and the dates of our several Patents.

DATES OF PATENTS:

September 14th, 1869, October 5th, 1869, October 4th, 1870, May 9th, 1871.

WARNING TO INFRINGERS:

The U. S. and Foreign Salamander Felting Company hereby notifies, cautions and warns the public—and particularly engineers and proprietors of Steam Machinery—that their patents for “ASBESTOS BOILER COVERING,” having been fully sustained by Repeated Decisions in the U. S. Courts, all infringers will be duly prosecuted.

Some of the more important of the above mentioned decisions were against the “ASBESTOS FELTING COMPANY, of New York,” and parties USING THEIR MATERIAL. Pamphlets containing full accounts of these and other cases will be furnished on application. It must be remembered that those USING an infringement are as liable to prosecution as those manufacturing and vending it.

All parties on this Coast, having used the

“ASBESTOS FEETING,” (of New York,) and MERRILL’S SO-CALLED “STEATITE FELTING,” (Which analysis shows to infringe in nearly every case), or any other infringing material, are hereby notified that they will in time be called upon for ROYALTY and DAMAGES; but are at the same time CAUTIONED against paying such royalty or damage to any but the authorized agents of the

SALAMANDER FELTING COMPANY,

WE WILL PAY THE HIGHEST PRICE FOR A GOOD QUALITY OF ASBESTOS.

Knowles' Steam Pump; for all purposes where Pumping is required

Office of Amazon and Glasgow Mining Co.,

San Francisco, Nov. 25, 1876.

A. L. Fish & Co., Agents for Knowles' Patent Steam Pump,

Gents: After using many devices for pumping mines I must say the DOUBLE ACTING PLUNGER MINING PUMP (Knowles' Patent), bought some time since for the Amazon and Glasgow mines, is seemingly as near perfection as it is possible to be. We carry steam 500 feet to the pump, raising water 400 feet, which it does easily with 40 pounds of steam, without the slightest jar on the pipes, and is perfectly noiseless. Gravel cannot wear the cylinder, and it is by far the simplest, cheapest and most economical way I know of for draining mines. I would cheerfully recommend them. Yours truly,

A. Caldwell, Superintendent.

Buy the Best.

Before purchasing an American Watch, examine the different styles manufactured by the **NEW YORK WATCH COMPANY**, at Springfield, Mass. They are the latest and best improved manufacture. You can depend upon them for fine finish, durability and perfect time. They are sold at favorable prices—in fact, no higher than many of the inferior styles. Examine into the merits of this Watch before you buy any other. Our word for it, you will not regret it.

DEWEY & CO., Publishers, S. F.**TULLOCH'S AUTOMATIC ORE FEEDER,**

Awarded the Centennial Medal.

The **TULLOCH AUTOMATIC ORE FEEDERS** have been practically tested during the last year and a half in 40 mills, of from five to 30 stamps each, and have, in every case, given perfect satisfaction. The Tulloch machine is so constructed that the drop of the stamp feeds the ore in just such quantities as the stamps require. Each drop regulates the supply required for the next drop, whether it be more or less, and this is the true principle of an automatic feeder. The tray moves longitudinally, and a stationary scraper forces the material forward at each backward movement of the tray, thus insuring the perfect feeding of all classes of ore, whether it be dry or wet.

We append a few extracts from the many testimonials which we have received from mill men and practical mining men, of the effectiveness and positive action of the Tulloch Feeder. We do not depend solely upon these testimonials, as we are aware that testimonials are easily secured for almost any machine, but the high character of the parties certifying to those herewith given, will establish their value and genuineness:

Mr. Jas. G. Fair has 23 in use; says: I regard them superior to any Feeder with which I am acquainted; I consider no mill perfect without them. Mr. E. R. Burke, Sumner mine, Kern county, has 18: They never get tired; no man living can feed a battery as well; they save us in labor alone \$48 a day. Mr. Green, of the Phoenix mill (12), Anador, writes: The first machine we had is working away; is as good as ever; have not spent a dime on it; in use 14 months; you need fear no competition on wet ores. Mr. W. H. Armstrong, of Consolidated Virginia mill: We are running 60 stamps with your Feeders; they give unbounded satisfaction; they have not cost the company one dollar since starting up. Mr. H. C. Bidwell, Supt. Green Mountain and Gold Stripe companies, Plumas county, writes: From the start they have done splendidly; no trouble whatever; requiring but little attention; a boy can manage them; the saving in both labor and castings is fully one-half over the old style of feeding by hand. Mr. Preston writes: I have four of your Automatic Self Feeders, and my mill men each and all say they are the best they have ever used. They are an improvement on all I have ever seen, being simple in construction, and good for either wet or dry crushing; refer to over 40 mills using them; they are guaranteed to give perfect satisfaction. Send for circulars.

F. OGDEN, 413 California Street, S. F.**PATENTED
CAST STEEL SHOES
AND DIES.**

Guaranteed Cheaper than the Best Iron.

IMPORTANT NOTICE.

Reduction in Price from 16 Cents
to 12 Cents Per Pound.

PASO ROBLES, CAL., October 18th, 1875.

DEWEY & CO.—Gents:—The letters patent for the Tiro Upsetter have come to hand. For the prompt manner with which you have brought the matter to a successful issue, please accept my thanks. Yours respectfully,
JOHN H. MERTZ.

THE MINING AND SCIENTIFIC PRESS is the leading journal in America. New processes and mechanical inventions are illustrated and discussed in its weekly issues. It is a 16-page sheet, handsomely printed, for \$4 per year. Dewey & Co., publishers, San Francisco.—*Mt. Lincoln News, Atina, Colorado.*

Metallurgy and Ores.**JOHN TAYLOR & CO.,**

Importers of and Dealers in

ASSAYERS' MATERIALS.

Chemical Apparatus and Chemicals, Drug-
gists' Glassware and Sundries, etc.

612 & 518 Washington St., San Francisco.

We would call the special attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our large and well adapted stock of

ASSAYERS' MATERIALS

—AND—

Chemical Apparatus,

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast.

Our Gold and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in grains and grammes, will be sent free upon application.

JOHN TAYLOR & CO.**THOS. PRICE'S****Assay Office and Chemical Laboratory,**

524 Sacramento St., S. F.

Deposits of bullion received, melted into bars, and re-
turns made in from 24 to 48 hours.

Bullion can be forwarded to this Office from any part of the interior by Express, and returns made in the same manner.

Careful Analysis made of Ores, Metals, Soils, Waters, Industrial Products, Etc. Mines examined, and reported upon. Consultations on Chemical and Metallurgical questions.

Nevada Metallurgical Works,

21 First Street, 3 doors from Market, S. F.

Ores worked by any process.

Ores sampled.

ASSAYING in all its branches.

Analysis of Ores, Minerals, Waters, etc.

WORKING TESTS MADE.

Plans furnished for the most suitable process
for working Ores.

Special attention paid to Examinations of
Mines; plans and reports furnished.

ery street, San Francisco, at pri-
ces according to the times.**

Continued from page 341.

were assayed and gave results as follows: No. 1, \$260.75; No. 2, \$188; No. 3, \$91.10. This ledge from which the rock was taken is from three to seven feet in width, and is sufficiently opened to admit of the extraction of it without much trouble. It was Wardle's intention to start out to-day with tools and supplies for the purpose of mining on this vein and taking out an amount of ore sufficient for a test by mill process.

MANHATTAN DISTRICT.

DISCOVERIES.—Belmont *Courier*, May 26: Mr. J. H. Sanders, one of the oldest residents of this county, who has always gone his pile on Nye, was in town this week. He reports rich discoveries in Manhattan mining district, situated about 15 miles southwest of Belmont. It has been known for years that this district is rich in minerals, but until recently no one thought enough of it to prospect it. Messrs. Sanders and Aldrich & Sturtevant resolved to give this district a thorough prospecting. They have located several claims, the principal of which are the North America, South America, Prince of Wales and Blue Ledge. They were rewarded last week for their past labors by the discovery of a rich ledge, the croppings of which can be traced for several miles. The rock from this ledge assays all the way from \$15 to \$70 per ton in value. In the Blue Ledge the assays show that the ore from that claim goes high in copper—90% copper, 5% silver and the balance lead, etc. These gentlemen intend to get to work immediately in these mines. Wood and water are plentiful in this district.

Arizona.

THE MINES.—*Arizona Citizen*, May 19: At no time within years, if ever, have the people hereaway been so elated and interested in mining matters. The extraordinary developments of the Rusk mine, by the Pima company, the wonderful reports from the Aztec district, the highly satisfactory results obtained from the San Xavier, and reports generally altogether, have created this great interest. People are also surprised to find large veins in the mountains everywhere examined, and locations are daily made by men of all occupations. New mining districts are being formed and increased development is going forward on all sides. The Pima mining company are pushing work on the 804 ft cross-cut, under the direction of Mr. Simonds. Col. Fred Drew took to San Francisco, on last Wednesday, samples of all the classes of ore from the mine. The bodies of ore now in sight are variously estimated at from 18,000 to 26,000 tons, which is said will all average over \$60 per ton. Capt. Voisard was in from Arivaca district, this week, and says the mines are developing satisfactorily, some of the ore being very rich indeed. We understand from Prof. Davis and Mr. Magee that active operations will soon commence in the Aztec mining district.

SILVER KING.—*Arizona Enterprise*, May 23: On the north and south extensions of the Silver King, the work is being pushed as rapidly as possible, and, in the course of a week drifting will be commenced from the bottom of the shaft on both mines. The shaft on the south extension is down 107 feet, and that on the north extension 130 feet. The Silver King proper is continuing to take out very rich ore. The news that the King is incorporated will tend to enliven the camp.

There are a large number of ledges both north and south of this place, which would pay some man with capital. The whole country is taken up, but, as a general thing, the owners are men who have no capital to work on. In fact, capital is the great desideratum in this section, and as soon as some which is time it must do, Pinal county will be one of the best counties in Arizona Territory.

The foundation for the mill at the Picket Post is progressing, and that place looks lively. Our town will eventually be there, for the Picket Post creek will furnish plenty of water for mills, families and the traffic of the Silver King and Globe district.

PECK.—From Mr. Peck, who arrived in town, yesterday, from the Peck district, we learn that the mining in that region are looking better than ever before. Upon the Silver Prince, Messrs. Houghton & Curtin have a large quantity of high-grade ore, which they are now sacking. Upon the San Francisco, Mr. Rice is busily at work developing the mine, and has out some very fine ore. This ledge is improving in appearance every day, and the work is showing it to be a good mine. The Black Warrior is mining and showing. Some very fine native silver ore is being taken out, and the mine looks better than ever. Several parties are at work upon extensions of the Peck and Occident, and find good ore all along the line.

FROM TURKEY CREEK DISTRICT. We learn that Pat Hamilton and Chas. Hall are busily at work with a force of men on the Turkey Creek bonanza, the Trinity, and are down to a depth of 40 feet. They have some very rich ore and the whole of the vein is high grade.

HUMBOLDT.—From Mr. Riggs, who arrived in town, yesterday, from Humboldt district, we learn that the work on the Tip-Top mine is suspended for the present, with the exception of the sacking of about 14 tons of high-grade ore, which is to be shipped to San Francisco.

Idaho.

GOLDEN CHARIOT.—Owyhee *Avalanche*, May 26: The operations at the Golden Chariot continue to go forward satisfactorily. The ninth cross drift is in nearly 200 feet. On the Crane and Driggs ledge the south drift is progressing favorably. The ore is steadily improving and promises the best results. At the 13th level all the indications are of the most promising character. The vein, at a distance of 340 feet from the shaft, is five feet in width and looking much better than at any previous stage of the work. The existence of rich ore in the immediate vicinity is regarded as certain. The progress made in this section of the mine, thus far, shows a passage over five distinct veins, all tending towards a great ledge that must sooner or later come to light. The hope of the country is centered in this work, and the vigilance and energy which have characterized the operations of the Superintendent during the past few months did fair to meet with ample returns in due season. The point now reached is at a greater depth than has hitherto been penetrated in the War Eagle mountain, and the prospects at every stage of the work is most cheering.

EMPIRE.—We are gratified at being able to state on information received from the most authoritative sources that the Empire is looming up in magnificent proportions. There is a force of nearly twenty men at work in the mine, and the developments of the past week are unusually promising and satisfactory. The rock which has been taken out for the past few days is liberally streaked with gold, and some of it assays away up in the thousands. None of it will crush less than \$100 to the ton, and the average will undoubtedly be considerably over \$200.

BELLE PECK.—At the Belle Peck the flow of water still continues to be a hindrance to active operations. The rich ledge in the Fotasi is beginning to attract much attention. Workmen are busily engaged in taking out good rock.

Nearly 100 tons of rock from the Lepley mine were crushed at the Golden Chariot mill recently. The entire bullion yield was \$2,450. It is believed that if the ore had been reduced by the roasting process the amount of bullion would have been nearly double.

SAN BUENOS.—A crushing finished on Wednesday of this week level was commenced by Col. O'Bannon some short time prior to his leaving us, as it was impossible to hoist by the incline the ore that was necessary to keep

Montana.

WORK RESUMED.—Cor. Butte *Miner*, May 28: At last we have a glimmering of light. The arrival a few days since of Mr. I. I. Lewis has been the cause of this break in our partial eclipse. Mr. Lewis has commenced work upon the Hope mine with a small crew of men. We hear that the level from No. 2 shaft is to be pushed through to the incline for the purpose of facilitating the hoisting of ore. This shaft level was commenced by Col. O'Bannon some short time prior to his leaving us, as it was impossible to hoist by the incline the ore that was necessary to keep

the mill at work steadily. The Speckled Trout mine cleared their shaft of water some days since and have employed a few miners and commenced work once more, much to the satisfaction of the denizens of this quiet town. Whether the new company (or the old company with the new name) the "Northwestern," intend putting their stamps in motion, we have not learned. If they conclude to do so, it will be for the purpose of reducing custom work, as at the present time they have but little if any ore of their own on the dump.

The Dexter mill started up yesterday. On coming to overhaul the machinery, which repairs were found necessary that was supposed, which accounts for the long stoppage. The mill is now in splendid repair again and there will be no protracted stoppage hereafter, Mr. Clark having ordered several sets of plates and dies, millers, etc., which can be put in without loss of time in case of breakages occurring.

All the mining ditches are flowing bank full and some water going to waste; the placers are now about all running, and this branch of the mining industry looks very bright and promising for the season. We are informed by parties recently at the head of the ditches that the snow is abundant, and with what has fallen in the past few days, there is little apprehension that the supply of water will be short for many months. In fact everything points to as lively a season as was had last year in the placers.

Messrs. Sloss & Barker furnish us the following in relation to their operations at Silver Lake: They have been working their mines during the winter, but had to suspend operations a few days ago on account of water, the melting snow sending down large quantities, some of which found its way into the mines and rendered work disagreeable. The ore in the Silver Lake mines seems to occur in shales or pockets, the veins in places pinching up and carrying no quartz. They have found a good body of ore, however, some of it very rich, assaying as high as \$5,000 per ton in silver. The consequent loss of time in cutting through the "hoss" makes their dump pile a little small for the season's work, but the mine is in condition now for hoisting plenty of high grade ore.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

EXCELSIOR S. M. Co.—May 28th.—Location: Arizona. Capital stock, \$10,000,000. Directors—R. H. Smith, R. A. Grant, J. M. Martin, W. S. Pettigrew and B. W. Reagan.

ARIZONA SMELTING CO.—May 29th. Object: To do a general smelting business in Arizona Territory. Directors—A. A. Webber, Joshua Hendy, J. H. Conway, J. F. Place and W. F. Hughes. Capital stock, \$100,000. **YAVAPAI CO. & M. Co.**—Location: Cerro Colorado district, Pima county, Arizona. Capital stock, \$10,000,000. Directors—J. P. Arcey, B. L. Tiffany, E. Sniffen, Caleb T. Fay, J. F. Cummings, H. P. Luby and S. F. Sniffen.

PACIFIC METALLURGICAL CO.—May 29th. Object: To work all precious and base metals, ores and tailings; to extract the minerals from black sand and gravel, and work the same; to purchase and acquire and to hire and lease such real estate, lands, mining location and ground as may be deemed essential to the working and reducing ores, tailings, sands and gravel situated on the Pacific coast. The Trustees are: William Holden, Julius Jacobs, S. F. Ambler, Solixas Solomons, William Eppelsheimer, Isaac N. Thorne and Aaron A. Adler. Capital stock, \$10,000,000, in 100,000 shares of \$100 each, \$175,000 of which has been subscribed.

CONCENTRATOR CO. M. Co.—May 29th. Location: Inyo Co. Capital stock, \$10,000,000. Directors—John P. G. Miller, H. P. Eayrs, Geo. A. Case, Wm. G. O'Hara, Ed. C. Hughes, F. A. Wilson and Rasmus Mikkelsen.

KIMBERLY COAL M. Co.—May 30th. Location: Alaska Territory. Capital stock, \$3,000,000. Directors—C. L. Dingley, I. E. Davis, J. P. Stearns, M. M. Kimberly and R. Sudden.

General News Items.

THE Tribune says \$106,000,000 worth of liquor is consumed in New York every year.

GEN. GRANT has arrived in England, and was received with great enthusiasm and ceremony.

THE Mariposa Gazette states that the rush of tourists to Yosemite this season is in excess of any previous year.

THE Tribune says: It is said that the English colonies have gained increased trade by the displays they made at the Centennial Exhibition.

THROUGH official channels a rumor has reached the State Department that Mexico is about to declare an additional 10 per cent. tariff on all imports into that country.

THE annual reunion of residents of Nevada county will be held at Badger's park on June 9th. The exercises will consist of addresses, poems, an oration by John Garber, music and dancing.

THE steamship City of San Francisco, belonging to the Pacific Mail Steamship Co., ran on a sunken rock on the Mexican coast this week and sunk. No lives were lost, but the steamer is a total loss.

THE Scherif of Mecca has placed the treasures of the Holy Shrine, the accumulated money gifts from pilgrims, at the Sultan's disposal. The treasures aggregate 200,000,000 piasters, \$4,000,000.

THE Secretary of the Treasury gives notice that the principal and interest on the 4,000,000 registered 5-20 bonds of March 3d, 1865, dated July 1st, 1865, and 6,000,000 coupons, will be paid at the United States Treasury, August 28th.

THE Chico murderers have been sentenced. Charles and John Slaughter, E. R. Roberts and E. Conway were sentenced to 25 years' imprisonment; T. W. Stainbrook, who stood trial, got 27½ years. The other indictments against them were dismissed.

HUNT, DOUGLAS & STEWART PROCESS.—We have given in this journal a detailed description of this process for the humid treatment of gold or silver ores associated with copper and other base metals, or ores free from base metals. It is now used in Colorado in connection with the Purvine wooden amalgamating pans and settlers. Mr. Stewart advertises in another column that the process can be adapted to any first-class gold or silver mill, at a reasonable additional expense.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

The "Mining and Scientific Press."

Our readers can do a good work for the PRESS and the mining interests, by calling the attention of their friends who are not already subscribers, to the merits of this journal. The MINING AND SCIENTIFIC PRESS is the oldest industrial journal on the coast, being now in its thirty-fourth volume, and has always been the advocate of the mining and mechanical interests of the coast. It has been so long established as to be standard in its character, circulating in every mining camp on the Pacific coast. We keep a complete record of the mining news of the day, and pay close attention to any new inventions, methods or processes which are likely to be of value to our practical and progressive readers. No miner or mechanic, who desires to advance in his trade, can afford to be without a home journal devoted to his interest, so they should all lend their assistance to maintaining one. A glance over this number of the PRESS will convince any one engaged in industrial pursuits that the journal is worthy of support and recognition. We desire, of course, to increase our subscription list, as it will aid us in still further improving the paper. With this number we issue an illustrated supplement of eight pages to accommodate our advertising patrons, so that the PRESS this week contains 24 pages, a large portion of which is interesting reading matter, closely set, interspersed with numerous attractive and instructive illustrations.

DEWEY & CO.**PATENT AGENTS.**

Office—224 Sansome St., San Francisco.

PATENTS obtained promptly; Caveats filed expeditiously; Patent re-issues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Soliciting Business promptly and thoroughly conducted. Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons, and our success and business are constantly increasing. The shrewdest and most experienced inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

DEWEY & CO., Patent Solicitors.
San Francisco, 1877.

Mining and Scientific Press

Is the leading mining journal in America, and enjoys a large circulation among the more intelligent operators and workers in the gold fields of the world.

As a scientific and mechanical representative of the Pacific Coast, it is decidedly popular and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special sphere unrivaled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer will find profit by its reading.

Subscription, \$4 a year in advance. Sample copies, post paid, 10 cents.

DEWEY & CO., Publishers, S. F.

Contents of Pamphlet on Public Lands of California, U. S. Land Laws, Map of California and Nevada, Etc.

Map of California and Nevada; The Public Land Laws of the United States; Table of Rainfall in California; Counties and Their Products; Statistics of the State at Large.

INSTRUCTIONS OF THE U. S. LAND COMMISSIONERS.—Different Classes of Public Lands; How Lands may be Acquired; Fees of Land Office at Location; Agricultural College Scrip; Pre-emptions; Extending the Homestead Privilege; But One Homestead Allowed; Proof of Actual Settlement Necessary; Adjoining Farm Homesteads; Land for Soldiers and Sailors; Land for Indians; Fees of Land Office and Commissioners; Laws to Promote Timber Culture; Concerning Appeals; Returns of the Register and Receiver; Concerning Mining Claims; Second Pre-emption Benefit.

Abstract From the U. S. Statutes.—The Law Concerning Pre-emption; Concerning Homesteads; Amendment Act Concerning Timber; Miscellaneous Provisions; Additional Surveys; Laws for Pre-emption, List of California Post Offices. Price, post paid, 50 cts.

Published and sold by DEWEY & CO., S. F.

Mining and Scientific Press Patent Agency.

THE MINING AND SCIENTIFIC PRESS PATENT AGENCY was established in 1860—the first west of the Rocky Mountains. It has kept step with the rapid march of mechanical improvements. The records in its archives, its constantly increasing library, the accumulation of information of special importance to our home inventors, and the experience of its proprietors in an extensive and long continued personal practice in patent business, affords them combined advantages greater than any other agents can possibly offer to Pacific Coast inventors. Circulars of advice, free.

Address,

DEWEY & CO.,

No. 224 Sansome St., S. F.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quicksilver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$2.50 coin, or \$3 currency, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE, \$7.50.

UNITED STATES**Mineral Land Laws, Revised Statutes, AND INSTRUCTIONS AND FORMS UNDER THE SAME.**

We have just issued a pamphlet containing the General Mineral Land Laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with Instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870. Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Registers' Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of \$500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizens; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO., Publishers of the MINING AND SCIENTIFIC PRESS, S. F.

THE EXPLORERS', MINERS' AND METALLURGISTS' COMPANION.—Comprising a practical exposition of the various departments of exploration, mining, engineering, assaying and metallurgy; containing 672 pages and 83 engravings. By J. S. Phillips, M. E. Price—cloth, \$10.50; in leather, 12; postage 50 cents. Sold at this office.

The Agonies of a Bilious Colic. The indescribable pangs of Chronic Indigestion, the debility and mental stupor resulting from a costive habit, may be certainly avoided by regulating the system with that agreeable and refreshing Standard preparation, TARRANT'S SELTZER WATER. Procureable at all druggists.

50 MIXED CARDS, with name, for 10c. and stamp. One pack (20 styles) Acquaintance Cards, 10c. Samples for 3c. stamp. M. DOWD & CO., Bristol, Ct.

Another Compliment.

LOS ANGELES, May 21st, 1877.

Messrs. Dewey & Co., Patent Agents, S. F.—Gentlemen:—I have just received my letters patent on machine for opening oyster shells, and compliment you upon your success. I shall not only contribute to you my own business, but also that of friends. Thanking you, gentlemen, for your promptness and the very thorough manner in which you have prosecuted this matter, I am, yours truly,
 T. W. TEMPLE.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Booth Gold Mining Company.—Location

of works, Auburn, Placer county, California.
 Notice is hereby given that at a meeting of the Board of Directors, held on the thirtieth day of April, 1877, an assessment (No. 2) of five cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, No. 320 California Street, Room 8, San Francisco, Cal.
 Any stock upon which this assessment shall remain unpaid on the fourth day of June, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on the twenty-fifth day of June, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Directors,
 GEO. R. SPINNEY, Secy.
 Office, 320 California St., Room 8, San Francisco, Cal.

California and Arizona Mining Company—

Location of principal place of business, San Francisco, California. Location of works, Cedar valley, Mohave county, Arizona.

Notice.—There are delinquent upon the following described stock, on account of assessment (No. 2), levied on the third (3d) day of April, 1877, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
Edmund Burch.	13	50	\$1.00
Edmund Burch.	15	500	10.00
Edmund Burch.	17	500	1.00
Edmund Burch.	18	400	4.00
Edmund Burch.	19	200	4.00
Edmund Burch.	21	200	4.00
Edmund Burch.	24	100	0.00
Benjamin Flint.	89	4,000	80.00
W. H. Hall.	41	2,500	50.00
James W. Thrift.	43	2,500	50.00
E. E. Rice.	44	2,500	50.00
J. Jewell, Trustee.	49	50	1.00
Martin Corcoran.	50	1,250	25.00

And, in accordance with law, and an order of the Board of Directors, made on the third (3d) day of April, 1877, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at Room B, No. 507 Montgomery street, on Monday the fourth (4th) day of June, 1877, at the hour of two (2) o'clock, P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.
 T. E. JEWELL, Secretary.
 Office, 507 Montgomery Street, San Francisco.

Dolores Consolidated Mining Company.—

Location of principal place of business, San Francisco, California. Location of works, Dolores Mining District, Esmeralda County, Nevada.

Notice.—There are delinquent upon the following described stock, on account of assessment (No. 1) levied on the seventeenth day of February, 1877, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
Blasdel, H. G., Trustee.	16	10,000	\$1,000.00
Blasdel, H. G., Trustee.	17	5,000	500.00
Blasdel, H. G., Trustee.	18	5,000	500.00
Blasdel, H. G., Trustee.	19	5,000	500.00
Drexler, L. P. & Co., Trustee.	3	25,000	2,500.00
Fry, J. D., Trustee.	7	10,000	1,000.00
Keene, J. R., Trustee.	9	10,000	1,000.00
Talbot, W. C.	3	100	10.00

And in accordance with law and an order of the Board of Directors, made on the seventeenth day of February, 1877, so many shares of each parcel of such stock as may be necessary, will be sold at public auction at the office of said company, on Monday, the sixteenth day of April, 1877, at the hour of two o'clock, P. M. of said day, to pay said delinquent assessments thereon, together with costs of advertising and expenses of the sale.
 J. W. CLARK, Secretary.
 Office, 413 California street, San Francisco, California.

POSTPONEMENT.—The sale of the above described certificates of stock is postponed from the 16th day of April, 1877, to the 18th day of May, 1877, and will then be held at the same hour and place as above named. By order of the Board of Directors. J. W. CLARK, Secy.

POSTPONEMENT.—The sale of the above described certificates of stock is postponed from the 16th day of May, 1877, to the 15th day of June, 1877, and will then be held at the same hour and place named above. By order of the Board of Directors. J. W. CLARK, Secy.

Excelsior Silver Mining Company.—Location

of principal place of business, San Francisco, Cal. Location of works, Lincoln County, Nevada.

Notice.—There are delinquent upon the following described stock, on account of assessment (No. 4) levied on the twenty-fourth day of April, 1877, the several amounts set opposite the names of the respective shareholders, as follows:

THE O'HARRA CHLORIDIZING FURNACE

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing 20 Tons in 24 Hours by this Process:

One man.....	\$ 4 00
One man.....	3 00
Wood—2½ Cords at \$3 per cord.....	5 00
Salt—1,600 lbs at 2½ cents.....	40 00

Cost of 20 tons.....\$52 25

Cost of one ton.....2 61½

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in Peavine District, Nev., and at the Exchequer mill, Alpine Co., Cal. For further information, apply to

AVERILL MIXED PAINT,

Was awarded the Highest

MEDAL AND DIPLOMA

AT THE CENTENNIAL EXHIBITION FOR A READY MIXED PAINT.

THIS CELEBRATED PAINT IS MANUFACTURED BY THE

CALIFORNIA PAINT COMPANY.

THIS PAINT IS MIXED READY FOR USE.

THE PUREST WHITE, AND OF ANY DESIRED SHADE OR COLOR.

It will not peel, crack, nor chalk off, and will last twice as long as the best white lead, prepared in the ordinary way. Is cheaper, handsomer, more durable and elastic than the best of any other paint.

Extract From the REPORT OF THE CENTENNIAL COMMISSIONERS.

"This Paint is quite different from paints in general use. * * * Work which has been done with it, some of it exposed for years to the moist atmosphere of the sea-shore, establishes its great durability. * * * It is mixed ready for use, easily applied, of great beauty, and economical."

Extract From the REPORT OF THE FRENCH (CENTENNIAL) COMMISSION.

"It possesses merits unattainable by the old method of combining paint. * * * It can be applied with great facility and perfect regularity; dries with a rich, glossy surface, and will not chalk or crack off. * * * It never separates, is always ready for use, and will not spoil when exposed to the air. * * * It can be applied by any one whether a practical painter or not."

PICKERING ENGINE GOVERNOR.

VALLEJO FOUNDRY, October 17th, 1876.

Messrs. NEYLAN & YOUNG, San Francisco,
Agents for "PICKERING GOVERNORS."

Gents:—The 10 two-inch Improved Speed Adjusting Governors I bought of you this year for my patent Straw Threshing Engines give splendid satisfaction. They far surpass for regularity of speed any Governor that I have ever seen, and I have seen all the best kinds; I have seen the main belt fly off the pulley several times this season while threshing, and the engine did not discover it, so perfectly was the speed maintained, until he was told of it; this I consider something wonderful; I consider the Governor absolutely perfect, so far as speed is concerned. I bought and put on to one of my engines a Shive Governor, to see which was the best, and after one season's trial I have no hesitation in saying they are far superior to any other Governor that I have seen or used. I wish you would send me the lowest price that you can furnish 25 Governors for next season's engines.

Yours respectfully,
J. L. HEALD.

The only Governor that has received awards at each of the International Exhibitions. American Institute Fair, New York, 1865, Two Medals; Mechanics' Institute Fair, Baltimore, 1865, Silver Medal; American Institute Fair, New York, 1869, Two Medals; International Exposition, Paris, 1875, One Bronze and Two Special Medals; International Exposition, Vienna, 1873, Medal of Progress and Decoration; International Exhibition, Philadelphia, 1876, Medal and Diploma.

THE GIANT POWDER CO.,

Ask your special attention to their IMPROVED GRADES OF POWDER, Viz:

No. 1 GIANT

Now the Quickest and Most Powerful Explosive Compound in the World.

No. 2 EXTRA, a New Grade,

Which will hereafter be our second grade. It is of immense strength,

Far Surpassing any POWDER of its Class Ever Before Manufactured.

NOTWITHSTANDING ITS GREATLY INCREASED STRENGTH,

Will be sold at the price of the old No. 2. Where a Powder stronger than ordinary No. 2 is needed, we invite a trial of this new grade.

No. 2. Our Powder of this Grade will Continue of the Strength of our No. 2 of Last Year's Make.

It is a Strong, Reliable and sure Powder, and will do excellent work.

SPECIAL ATTENTION IS CALLED TO THE REDUCED PRICE AT WHICH WE WILL HEREAFTER SELL THIS GRADE,

JUDSON POWDER. This New and Valuable Powder is Rapidly Coming into General Use as a Substitute for
Common Black Powder, to which it is in all respects far superior.

Price 15 cents, or by car load 13 cents. In Cartridges, 2 cents extra. Discount as usual to the trade on our various grades of powder. Caps, single, double and triple force, also, fuse of all brands always on hand.

Send for Pamphlets and information to

New Break-Circuit Chronometer.

At the meeting of the California Academy of Sciences held May 21st, the President, Prof. Geo. Davidson, of the U. S. Coast Survey, exhibited the drawings and the working of an ordinary chronometer changed to a break-circuit.

In the earlier work of the U. S. Coast Survey for the determination of the difference of longitude between stations by means of the telegraph, the signals were transmitted by means of the pendulum or of the escapement of an astronomical clock, breaking the circuit. To transport a delicate clock over the rough roads of California was detrimental to its accuracy of rate, and Prof. Davidson proposed to himself the problem of changing an ordinary chronometer into a break-circuit chronometer at a trifling cost; but the chronometers examined were constructed with such an arrangement of banking-piece and detent that he did not succeed.

The subsequent construction of special break-circuit chronometers by the regular makers seemed to leave little more to be desired. But when executing some telegraphic longitude work in Japan in 1874-75, the weakness of the method of using clocks or chronometers, when both heat and record sidereal seconds upon a single pen chronograph, again brought the problem before him. In that work it happened upon two nights that the chronometers at Tokio and Nagasaki broke at the same epochs, and it was therefore impossible to directly decipher or separate the synchronous signals on the record without resort to unusual expedients. These were successful; but had a mean time chronometer, or an ordinary sidereal chronometer breaking half seconds, been available at one end of the line for the making and transmission of signals, that trouble would have been obviated.

The opportunity to study the question was not again afforded until last June, when regulating one of his chronometers he clearly saw how the problem was to be solved.

In the more recently made chronometers, the "banking-piece" and the "detent" are separately attached to the plate, near its outer edge. The figure shown on this page exhibits the relation of these parts, and of the balance and escape wheel. *P* is the chronometer plate; *W*, the balance; *E*, the escape wheel; *D*, the detent; *G*, the gold or passing spring of detent; *B*, the banking-piece; *I*, the newly introduced insulating plate, upon which the blocks of the detent and banking-piece are secured; *A*, the set screw of the banking-piece; *C*, the detent, resting on the point of the set screw; *J*, the jewel standing up from the detent, and against which each tooth of *E* rests in turn; *R*, the jewel in the verge or upper roller of the arbor of the balance; *S*, the jewel or pallet in the lower roller of the arbor of the balance; *T*, *U*, *V*, etc., the teeth of the escape wheel, of which there 15 in chronometers beating half-seconds; *L*, *L'*, wires through local battery and chronograph helix; *L*, *D*, *C*, *A*, *B*, *L'*, the course of the electric circuit through chronometer.

In these parts, the jewel, *J*, of the detent, rises above the plane of the detent, and also above the gold or passing spring, so that the teeth of the escape wheel can rest against it and at the same time be clear of the gold spring. The outer extremity of the gold or passing spring is attached to the outer extremity of the detent at the block; and the free end of the gold spring is moved only by the projecting jewel, *R*, of the verge or upper roller of the arbor of the balance.

When the balance turns in the direction contrary to that of the arrow, this jewel, *R*, of the verge, passes the end of the detent, which is too short to be touched, but strikes the free end of the gold spring, and pressing it back, passes it. But when the balance turns in the direction of the jewel, *R*, strikes the free end of the gold spring, which now presses against the free end of the detent, which is thus carried away from its contact with the set screw, *A*, of the banking-piece, *B*, and far enough to free the jewel, *J*, of the detent from the tooth, *T*, of the escape wheel, which then springs forward,

ward, whilst the tooth, *V*, impinges upon the pallet, *S*, and thereby imparts its impulse to the balance. When the tooth, *T*, has escaped from *J*, the detent springs back to the set screw, *A*, before the tooth, *U*, has come forward to *J*, which is in place to receive and hold it back until the next similar break occurs in half a second.

Taking advantage of the relation of these parts and the insulation afforded between the verge, the lower roller, the escape wheel and the detent through the jewels, *J*, *R*, and *S*, Professor Davidson insulated at *I* the blocks or affixed ends of the detent, *D*, and of the banking-piece, *B*. The part of a circular area having a radius of three-eighths of an inch, was drilled out near the edge of the plate to the depth of about one-eighth of an inch and inlaid with a hard, insulating material tooled flush with the face of the plate. Upon this was secured the blocks of the detent and banking-

sec., 1 sec., 2 sec., where three consecutive second breaks followed each other and thus indicated the commencement of each minute.

The second was an ordinary mean time chronometer by Hutton, changed under Prof. Davidson's direction to a break-circuit, by Mr. Charles Pace, and breaking every half second. The break of this chronometer, recording half seconds, was one-half the length of the break of the chronometer recording each two seconds. The sidereal chronometer gains upon the mean time chronometer one-half second every three minutes and three seconds, and there was a practical coincidence of beats at each such period.

THE SUTRO TUNNEL.—In an interview, Mr. Sutro gives the following information with regard to the progress of the famous tunnel that bears his name: The header is now in about 17,000 feet. The future rate of progress is ex-

DAVIDSON'S BREAK CIRCUIT CHRONOMETER.

pected to average about 300 feet a month. Work has been prosecuted for eight years, and the average cost has been about \$1,000 a day. The exact time of reaching the Comstock proper, at the Savage workings, cannot at present be definitely fixed. One estimate is that ten months more will suffice. At present the intention is simply to push the tunnel ahead as expeditiously as possible and disregard all side issues. The work of prospecting has never been prosecuted in any way, and will not be attempted.

It is evident, from this arrangement, that the current from the battery passes through the block and banking-piece of the set screw, *A*, and thence through the detent, *D*, and its block to the other pole of the battery; and that the record upon the chronograph is made when the circuit is broken by the detent leaving the set

HARRIS'S PATENT LATHE-DRIVER.

screw. The length of the break is about one-twentieth of a second.

In those chronometers designed for breaking the electric circuit to make the chronograph record, special means have been introduced by which the beginning of every minute is noted, although the observer has to make the record of the minute; but in the adaptation of the ordinary chronometer, as above described, this designation of each minute by the chronometer itself cannot be accomplished, and the observer must carefully note upon each sheet the beginning of one of the minutes.

The Professor exhibited two chronometers, breaking circuit and making their records upon the fillet of a field chronograph; one was a regular break-circuit chronometer, by Frodsham, breaking every even second, except at the

ed until the tunnel has been put through. Mr. Sutro expressed the opinion that before the Savage ground was reached the tunnel might be expected to cut some valuable ore body, and that he, in common with many mining men, would not be surprised at such an occurrence.

THE WEATHER IN MAY.—The variations of the weather in May in this city, as reported to us by the U. S. Signal Service officers, were as follows: highest barometer, 30.052; lowest, 29.812. Highest temperature, 75°; lowest, 48°. Prevailing direction of wind, west; greatest velocity of wind, 28 miles per hour. Total number of miles, 9,147. There was one rainy day, when 1.8 inches of rain fell. The total rainfall, since July 1st, 1876, has only been 11.03 inches.

Items of Interest from the Mines.

We give below items of interest from prominent mines, most of which are collated from letters of the respective Superintendents on file at the offices in this city:

The Gila shaft is now down 134 feet, with the bottom in hard lime.

Average assay of Chollar ore is \$24.16 per ton. Six hundred and twenty-three tons were taken out last week.

The flow of water in the upraise of the El Dorado South continues heavy.

In the Consolidated Virginia they are yet engaged in enlarging the south drift (the main air passage) on the 1550-foot level. The new drift on this level south and east of ore stopes has been extended 18 feet the past week. The ore is very fine. On the 1650-foot level the ore breasts are looking very finely. The south drift has been connected with the deep winze. This connection is being enlarged to admit of the free passage of air.

The west drift on the 1750-foot level of the C. & C. shaft has been extended 40 feet the past week; total distance from shaft, 100 feet. The level is very hot. The flow of water continues.

In the Justice, the east drift on 1150-foot level is still advancing through a very favorable formation, and every foot of progress the flow of water increases, but not in sufficient quantities to retard the progress. South drift on 1000-foot level is advancing through a very favorable ore body, which continues to expand as progress is made. Winze sinking from 800-foot level is looking well, and is entirely free of water. A very marked improvement has occurred in face of 750-foot level, north lateral drift. Improvements consist of a better quality of ore found, and the vein, to all appearances, is widening out to a very respectable width. The ore-producing stopes throughout the company's mine are looking and yielding extremely well.

From the 19th to the 26th ult the Manhattan reduced 112½ tons, the assay value \$23,281.07. Of this amount there was purchased 48 tons of an assay value of \$11,524.80. At the first shaft, the stopes on the upper levels are being cleaned up, preparatory to abandonment, they being worked out. The 500. west drift has shown some very good indications. The 570 east drift has met a slip in the ledge, cutting it entirely off.

Obviating the Use of Numerous "Dogs."

We saw this week at the shop of Joshua Hendy, corner Fremont and Mission streets, one of Harris's patent lathe drivers or dogs, a long needed and successful tool, of which Mr. Hendy is now manufacturing a large number.

It is constructed so as to drive regular or irregular shapes and will allow work to be turned straight or tapering without making any change in the driver. This is accomplished by the ring, with driving jaws attached, as seen in Fig. 2. The ring is fitted loosely in a recess formed between the two nuts, so as to allow the outer ends of the jaws to grip any irregularity without having any tendency to press the work from off its center.

Fig. 1 shows the driver ready to be screwed on the spindle of the lathe. To operate the jaws, the outer nut is run back, allowing the jaws to receive the work on its center. The work is put on the lathe on its centers and the lathe started in motion. All that is necessary is to press on the nuts, checking its revolutions, which will cause it to close the jaws on the work, gripping it firmly. The jaws can be spread wide enough to pass over any ordinary inequality in the work. Fig. 2 shows the ring with driving jaws attached.

This is really a very useful lathe driver and obviates the use of numerous "dogs." It was found by experiment at the Central Pacific shops at Sacramento that on small work it saved two hours a day over a lathe running alongside of it with the ordinary appliances. This tool is endorsed by such persons as Prescott, Scott & Co., Union Iron Works; Pendergast, Smith & Co., Etna Iron Works; Hinchley & Co., Fulton Iron Works; John T. Wilson, master mechanic, S. P. R. R.; W. H. Milliken, master-mechanic, machine shop, Sacramento, etc. These tools are being made here by Mr. Hendy, and a good many of them are being shipped East.

CORRESPONDENCE.

Calaveras County Mining Interests.

EDITORS PRESS:—San Andreas, the county seat of Calaveras county, occupies a central and elevated position in a broken and hilly part of the county, where nature's roughness seemed hardly to need the help of the miner to make chasms and precipices and piles of cobble quartz. But everywhere as you travel through the county you see the marks of the early miners' work.

The town and environs probably contain about 500 population. During court weeks it puts on lively airs; has a first-class hotel, kept by Cavin & Co., and restaurant by H. Watson; about six stores, and well represented in the trades and mechanical arts. The able county paper, called the *Citizen*, issues weekly.

At present not much mining is going on near town, though gold exists on every side, and

The Mother Lode

Of Amador county passes about one mile west of San Andreas, where are made some very favorable locations, for example the Cash mine and San Andreas, on which two well timbered shafts have been sunk 40 feet and 50 feet and cross-cuts run which show large bodies of sulphuretted gold ore. Average thickness of ledge matter, six feet; length of claim 1,500 feet. It is considered to be on the true Mother lode of the Hayward mines of Amador county. The ledge is found between a slate foot wall and granite hanging wall. Direction north and south, nearly, with an eastern dip of about 70°. Connected with the mine is a water ditch 27 miles in length to convey water to the mine. Prospect workings have yielded as follows: 10 tons unassorted ore, \$13 per ton; a small lot worked in San Francisco gave \$46. When pounded and horned shows well. The early placer mines on the line of this lead or belt paid generally very well. Mr. Benj. Thorne, one of the principal owners in these mines, is contemplating more extensive improvements and developments thereon, and, when completed, the mine will be able to announce its own value and that also of hundreds of other as yet undeveloped bonanzas in Calaveras county.

Mokelumne Hill

Yet stands and maintains much of its ancient grandeur, though so often tested by fire. There are not as large mining operations as formerly, still there is considerable trade in gold; but the glory of the place now might be its fine, elevated residences, with shades, fruits, flowers, birds, honey bees, and, in fact, all the luxuries of a city and farm home on a five or ten-acre tract on which some mainly depend for their income or living.

Jenny Lind,

Formerly a lively little mining town of near 100 dwellings and business houses, is now down to two stores, a saloon and a hotel. It depends mainly for its support on the farm trade from the adjoining good bottom lands. Four miles distant is

Milton,

The railroad depot for the Copperopolis railroad running from Stockton. It occupies an elevated site amidst the foothills, and, judging by extent of town lot stakes, it is the intention of its proprietors to try and supply all demands for lots; and they can be encouraged by the fact that there is plenty more ground adjoining that seems far better suited for town lots than for cultivation. It contains three stores, hotel, smith, harness and shoe shops, public hall and school-house.

Copperopolis,

Now quite dull by the stoppage of mining operations, is pleasantly located, and shows in its substantial buildings that it was built up at a time of large expectations. The adjoining country, sparsely settled by small farmers and sheep men, will not keep up the town that sprang up in a mining excitement and anticipated a rapidly increasing population. This town has but repeated the old lesson taught by so many cities before its day. Following up the rugged hills by a passable road, say 10 or 12 miles, you reach Altaville and its adjoining city, Angels, each a beautiful and thriving town, supported by mines and farms. Several arastars running by water power, a foundry, etc., gives quite an air of business.

Vallecito,

Another pleasant camp of a few stores and mechanics' shops, to accommodate miners and farmers, who seem to be getting along quite harmoniously. The main depot for all kinds of supplies is yet at the old stand of A. M. Mitchell, who seems to be doing a thriving business.

Five miles' ride on a moderate up-grade, that passes some creek mining, brings you to the once renowned

Murphy's Camp,

Or Flat, which is beautifully situated among rocky hills that shelter it from some of the severe winds. The mining at present is not very active, yet there are valuable interests in the mines, and will be gold taken out for years to come. The residences are hard to see, they are so hidden by shade and fruit trees. The Sperry hotel still maintains its high standard

of excellence and in all that pleases its guests Mr. Atwood proves his ability to run a hotel.

In all these mining towns they seem to keep up social, educational, and generally some general religious privileges, such as sabbath school, preaching, or the reading of some religious discourse. At Murphy's I heard one of Rev. Mr. Moody's sermons well read by a lady, who had a very attentive audience. Afterward she conducted a very pleasant sabbath school. In every village we now hear the organ and piano, showing that refined society is not confined to the valleys.

C.

The Hunt, Douglas and Stewart Process.

EDITORS PRESS:—In the issue of your paper May 5th, is an article by Mr. C. H. Aaron, to which I desire to reply as briefly as possible. When I wrote my circular on treatment of gold and silver ores by the Hunt, Douglas and Stewart method, in connection with amalgamation as practiced by me, I did so as a practical millman to other millmen, and not as a professional chemist; and while I made some errors in stating chemical reactions, yet the practical results observed by myself and others in working base metal ores are substantially correct, and the language used will, I think, be clearly understood by all practical millmen. For instance, what I call sulphite of silver, Mr. Aaron, in referring to similar observations or experience, calls "multiple sulphates." In the year 1872 I noticed that, although we had the best of Varney pans, yet we could not amalgamate to within 8% and sometimes 15% of the furnace chlorination as tested by hyposulphite of soda. Upon investigation I found that while 92% to 95% of the silver in our roast was soluble in hyposulphite of soda, yet only 75% to 82% was chloride of silver as tested by ammonia water.

There being no sulphate of silver present as tested by hot water, and still not any noticeable per cent. of raw or undecomposed ore, therefore as it was not a sulphide, nor yet a chloride, nor yet a sulphate, and yet had taken up oxygen, I gave the name of sulphite of silver, supposing it to exist chemically combined with the sulphate of lead or the sulphites of lead and zinc.

Now for the remedy, for it is of the utmost financial importance that this should be overcome. I have found nothing that gave as good practical results as leaching with a bath of protochloride of iron and salt, the ore to contain, either natural or artificial, some per cent. of oxide or suboxide of copper. Said bath when applied to oxidized copper ore was patented in 1869 by Messrs. Hunt and Douglas, and as applied to silver ores was patented in 1874 by Hunt, Douglas and Stewart. Further practical workings during the past year have proven the fact of still greater utility in using said bath with mercury and metallic copper in wooden vessels, so arranged that the recovery of said bath should be economical and rapid; and thus used over and over again similar to the use of mercury (for which a patent is also applied for). And in presenting our improvements to the attention of the mining and milling community of the "coast," I do so desiring the fullest investigation and gentlemanly criticism, and if our improvements shall stand the test of time, I will not feel much depressed in having made a few errors in stating chemical reactions as set forth by Mr. Aaron.

J. O. STEWART.

Georgetown, Colorado, May 16th, 1877.

The Mechanics of Pan Amalgamation.

EDITORS PRESS:—It is not my purpose to take up the question of "not grinding" or "grinding" in pans, but to deal of such points as are or should be as applicable to one as the other.

Nobody will disagree to the assertion that for amalgamation a good circulation is required, but the numerous differing theories, or rather ideas, to attain this are illustrated in the various patterns of shoes and dies now seen in use. By their shape shoes and dies naturally divide themselves into two classes. First, inside feed—or when the pulp enters under the muller at the center; Second, outside feed, or the reverse of class first. In observing the pulp in motion, where no wings are employed, it will be seen that the pulp rolls up at the sides and down at the center, taking a spiral course around the pan; that with the inside feed this spiral course is uniform throughout and extends under the muller, while with the outside feed the spiral course is only above the muller, and at the center there is a boiling up.

For convenience we may say that two forces operate to give motion to the pulp; force direct with the muller and centrifugal force. In shoes that give an outside feed the advance edge touches a radius at the end toward the center, while the outer end extends ahead. The action of this may be compared to a plow throwing its furrows to the centre or against centrifugal force, which is power lost. Shoes of this class, to work successfully, require to be at the outer end about one-quarter of their length ahead of the radius. With shoes which give an inside feed the outer end falls back of the radius, or acts as a plow throwing its furrows outward and with the centrifugal force. Shoes of this

class do good work when their outer end is about one-sixth of their length back of the radius. These shoes give a current exactly as does a centrifugal pump; the slip is the amount taken under the shoe and it should be equal in its entire length, which is only acquired by a straight shoe.

Shoes and dies should be made to operate together to form the same current (in many mills they may be seen to induce directly opposite currents,) and when the dove-tails are alike in muller and pan there is no objection to, and much in favor of, having them of one and the same pattern.

The foregoing principles are as true for a "slum muller" as for any other, only a "slum muller" should have deeper grooves and perhaps a stronger draft. An old idea was to create a current by wings, but this did not extend under the muller or through the quicksilver. Wings of proper shape may be employed to add to the capacity of the pan by throwing the top current sooner to the center.

Mullers should be very open at the center. There are still two difficulties often met which shorten the service of the pan-driver. First, in many mills the toe wears out, and an otherwise good driver must be thrown away; a sure remedy is to make the toe-square amply large and a true fit to the muller, better if it requires to be hit lightly with a hammer to turn it to place. Second, the bore of the driver often wears oval with the long diameter through the key seats; by using spindles with three or four leather no wear will ever occur.

Whatever of theory this article contains the writer has thoroughly proven by practice.

M. P. BOSS.

Mining in Amador County.

EDITORS PRESS:—Volcano, Amador county, in common with the other mining towns, has never recovered from destructive fires that visited it when its more flush days of general mining had passed. But even now it is a beautiful mining town, having very many neat and luxurious residences, adorned with fruit, flowers and ornamental shrubs, and trees in abundance. The business houses are largely of stone and brick.

There are various stores, in all about half a dozen; the mechanics' shops very well represented; a photographic gallery and drug business is carried on by D. S. Boydston. This present year is alike for miner and farmer for scarcity of water, thus allowing but little gravel mining this season. But the little valley and mountain ranches seem very green and prosperous when compared to many of the lower valley ranches.

Volcano has a good local trade from the surrounding ranches and the various lumber and quartz mills for 20 miles above. Has a daily stage out by Jackson 12 miles and thence 12 miles to Ione City to railroad. There are many valuable mining properties in way of quartz and gravel claims here, abundantly proved to be rich, but now requiring some small outlay of capital to open them properly for successful working. The hopes of the camp are now brightened by the energetic movement of the

Volcano Gold Gravel Mining Company, A San Francisco incorporation with office at 331 Montgomery street. The company hold a tract of the best mining gravel of all this region, but owing to lack of drainage could not be worked to bed-rock. To obviate this difficulty they secured ample rights of way down the main ravine and are now running a working tunnel eight feet by eight feet in the clear, in the solid rock, which will, in less than 3,000 feet, strike their claims, 40 feet below the former workings, and afford an outlet for working many valuable mines.

The principal mover of this enterprise, Mr. George Muck, President of the company, has his name properly coupled therewith, as it is known as

The Muck Tunnel.

Now running three eight-hour shifts, and all first-class white labor under the Superintendent, L. E. Bamber; P. N. Peck, wood mechanic. The car is run by water power and a wire cable, a very economic success. Work began July, 1876, and have now completed over 600 feet, and have all their shop arrangements complete; will soon call to their aid the latest improved power drills, with which they confidently expect to reach their claims early the coming winter. To do this every foot of tunnel run will require the blasting and removing of over 10,000 pounds of hard rock, but the live interest shown by those in charge of the work is the best assurance that it will be successfully completed. It is not every mining camp that has an enterprise of such certain and apparent value as this, and yet it is a fact that in almost every part of Calaveras and Amador counties are

Openings for Small Capital

To engage in straight and legitimate mining, with ample assurances of success; and I am glad to see some one here and there taking hold in a quiet business way to properly open up old claims of gravel and quartz. Here and there can be heard the unpretentious little five or 10-stamp water mill doing its prospect work.

If only a small fraction of the wildcat stock money had been here invested in actual mine development, instead of going to enrich the office and street brokers of California street,

there would have been for the many a better prospect than now.

David Robinson & Sons, who have fine hill ranches on ridge three miles north of Volcano, also have a good five-stamp prospecting mill run by water power, with which they are prospecting several quartz leads. This looks like a careful way to prospect safely.

This country is full of opportunities for doing that safe kind of prospecting with even small means.

C.

Volcano, Amador county, May 28th, 1877.

The Lead Market.

We are in receipt of a circular letter from Edward A. Caswell, a metal broker of New York City, giving some of the causes of the present depressed condition of the lead market. His remarks are directed more particularly to the Missouri and Illinois lead miners, but they are, nevertheless, of interest to the lead producers of other sections. He says:

The fall in the price of lead last autumn was unexpected and unusually rapid, but the cause was a larger supply than the trade could absorb. The reaction from six cents currency in November, the lowest point touched, was slow, and as late as the end of January the price had recovered only to six and one-quarter currency. At that time the apparent and prospective supply was fair, and the legitimate price, according to the immutable laws of supply and demand, should have ranged through the spring from six to six and one-quarter cents, and there were no valid reasons for an advance beyond the latter figure.

At the beginning of March a speculative purchase was made simultaneously in St. Louis and New York, amounting in all to nearly 2,000 tons, an insignificant quantity compared to the supply and to the objective end which the buyers had in view. The price then advanced rapidly until it touched six and three-quarters cents, a figure which at that time was only two dollars per ton below the cost of Spanish lead laid down in New York, duty paid. It was therefore evident that speculation could in no case advance the price any higher and large buyers declined to take lead at that figure. A few small sales were made at the top notch, six and three-quarters cents, but within three weeks' time over 1,500 tons were sold in New York at or about six and one-half cents, currency. The parties who bought on speculation "held the candle" sufficiently high for other holders and agents to see their way clearly to selling at high prices, which they did freely. These sales were distributed among all the large consumers, and gave them so sufficient a supply that they were then satisfied to wait and watch the turn of affairs. Heretofore, the production of February, March and April, has been appreciably less than the consumption of those months, and during that period all the surplus was used up, and we began the summer with very light stocks; but this year not only has Missouri kept steadily increasing, but the output of argentiferous bullion in the first four months of 1877 exceeded that of 1876 by over 4,000 tons. The incoming supply was ample for the spring demand (rather a light one), and the stocks held on speculation proved to be a surplus, and were consequently unsought for by any anxious buyers. While the stocks on hand January 1st, 1877, throughout the country were not much over 3,000 tons, they are to-day nearer 6,000 tons.

It has been stated that the decline in price was owing to a "bear" movement in this city, but the incorrectness of this statement must be evident to any careful observer of figures and facts. There have been no sales made to depress prices, no rumors started, no importations, nor in fact any extraneous efforts to bring about a decline; on the contrary, sales have been from first hands and at the best price obtainable. The market has fallen of its own weight, and must recover either by fresh speculation or when the price gets so low that production is curtailed.

THE Black Hills Times of a recent date says: The influx of gold seekers is assuming vast proportions and surpasses the most sanguine prophet of a month or so ago. They are coming in upon every road and trail, and from every quarter of the Union, and represent all ages, sexes and conditions. The rush by the Fort Pierre route has increased greatly within the past two weeks, and there are now over one hundred arrivals daily. Steamboats leave Yankton every other day for Fort Pierre heavily loaded, and there are no longer any delays. Eight new coaches, fully equipped with extra horses, were shipped to Fort Pierre last Monday, to run between that place and Deadwood, making the trip in two days by daylight, and were to begin running Monday last.

THE Deer Lodge, Montana, Northwest, of May 18th, says: Miners are commencing to leave Deadwood to prospect the Wind river, Big Horn and Tongue river country. There will soon be a permanent cessation of Indian hostilities in that region. There is a superabundance of men in the Black Hills proper, and of these who have sufficient means many will prospect toward Montana this summer. There are also many prospectors on the Yellowstone who will move to the south as soon as it is considered safe. These circumstances indicate that if there is gold in paying quantities in that much suspected and little prospected region it will be discovered this season.

MECHANICAL PROGRESS.

Mixtures for Steel Tempering.

The *English Mechanic* furnishes the following formulas for tempering small steel articles: By melting together about one gallon of spermaceti oil, two pounds of tallow and a quarter pound of wax, a mixture is obtained very convenient for tempering any kind of steel articles of small size. Adding one pound of resin, it is used for the tempering of larger articles. The addition of resin must be made with care, for an excess of this material renders the steel too hard and brittle. After several months of use the mass loses its energy; it must then be wholly renewed, taking care to thoroughly cleanse the bottom of the tub which contained it. Another mixture of which practice has likewise proved the efficacy, consists of 20 gallons of spermaceti oil, 20 pounds of tallow, 10 gallons of ox-foot oil, one pound of pitch and 3 pounds of resin. The pitch and resin are melted together, then the three other materials are successively added, and the whole is heated in an iron pot till all the water is evaporated. This is ascertained when the mass takes fire at the approach of a burning chip of wood; the flame is put out by hermetically shutting the pot with a cover. The tempering is effected in both cases as follows: Saw blades, for instance, are heated in special ovens, and when they have reached the temperature they are dipped in the mass contained in tubs arranged side by side. For a continuous manufacture a certain number of tubs are used, so as to allow the mass time for cooling during the progress of the operation. As soon as the blade is cooled it is withdrawn from the bath and cleaned with a piece of leather, so that there remains still on it a thin layer of grease. It is then passed over a coke fire till the grease catches fire and burns with a clear smoke. In this way the blade acquires elasticity. If it is desired very hard, a part only of the grease is allowed to be burned; the more softness is desired the more the burning is completed. For springs the flame is left to burn itself out. If the objects are of various forms and sizes the burning is repeated on the several parts till all the parts are deemed equally tempered. The blades are finished by hammering and heating them again on a clear coke fire till they return to a straw yellow hue. The coloration is then taken away by washing in diluted hydrochloric acid, and afterward in plenty of water.

A NEW STYLE OF STEAMBOAT.—The *Baltimore Sun* says: George G. Caldwell, a Baltimorean, has invented a steamboat called the *Alpha*, without paddle wheels or propellers, which is projected by the repellant power of water. She is 40 feet long, 10½ feet beam, and four feet draft, with a 16-horse power horizontal boiler. Two streams of water by means of a force pump, are ejected by steam at the stern or bow as desired, below the water line, through two five-eighth inch nozzles, and the force of the streams against the larger body of water propels the boat. She obeys her rudder readily. The object sought to be obtained by the invention is the propulsion of steamboats on canals with as little disturbance of the water as possible. Mr. Caldwell recently took a number of persons on an experimental trip of the *Alpha* down as far as Fort Carroll, which was quite satisfactory. She has the appearance of an ordinary harbor tug, and moves through the water with a speed of nine or 10 knots an hour, but unlike a tug, makes no waves, and disturbs the surface of the water very little. During a stoppage made on the trip the hose was attached to nozzles and a stream was thrown 100 feet, to show the efficacy of the boat in extinguishing fires. Mr. Caldwell proposes to take his boat to Buffalo to compete for a prize offered by the managers of the New York canals.

PUDDLERS' PLUGS.—An English exchange notes an improvement in stoppers for closing the discharge openings of ladles or vessels used, especially in the Bessemer process, in the filling of the ingot molds. Mr. A. Mason, of Horwich, near Bolton, has invented an improved method of attachment, whereby the stoppers are not so liable to become detached from the rods as when previous methods of attachment are employed. He forms a slot or opening extending from one side to about the center of stopper, so that a rod formed with a head can be passed through the slot into a central position in the stopper, the remaining space in the slot being then filled up with ganister or refractory material. He prefers to form the rod with a tee head, and to so form the slot as that when the rod is introduced into position and turning a quarter round it cannot be drawn out of the stopper in that direction of its length. He makes the slot wider inside the stopper than at the outside, so as to retain the filling material.

A NEW PULVERIZER.—A disintegrator and grinding or pulverizing mill is described in the *Moniteur Industriel Belge*, which consists mainly of an internal and external cylinder, the former revolving at a not very high speed and carrying with it a series of shot or balls fitting loosely in hemispherical holes arranged along a spiral line round the cylinder. The machine is used for pulverizing various substances, such as grain, drugs, ores, etc., and is very simple.

How to Lay Street Railways.

At a recent meeting of engineers in London a paper was read by Mr. R. Souttar on street tramways. He said that Portland cement concrete formed the best foundation for a tramway, but care must be taken to give it time to set before laying and paving the lines. Where the work had to be hurried, bituminous concrete was preferable. Rectangular cross sleepers injured the concrete by their vibration, but if they had slightly beveled sides, this objection would be overcome. Tramways with cast-iron bearings had been constructed in this country to a limited extent, but timber was preferable, as the jarring was diminished, and the traveling was rendered noiseless and agreeable. The life of the rail was probably increased, and the concrete was saved from injury. Flat grooved rails, spiked through the groove, were first used, but the spike-heads wore so quickly that it was necessary to adopt a side fastening, and flanges were added to the rail, with holes into which clips were driven. The objection to this rail was that the fasteners projected and kept paving stones away from it. The author had introduced a rail, the flanges of which were brought in beneath the thickness of the clip, so that the clip could be driven flush with the rail. The paving of a tramway was expensive, but indispensable, as without such protection the rails would be shaken loose, forced out of gauge, and worn quickly. A row of paving stones on each side of the rail, with macadam between, was unsatisfactory, as it could not be kept in repair, so that the horses were lamed by running on an uneven roadway. Experiments had been made with wood, concrete, and asphalt paving; but the wear along the sides of the rails was so great that nothing would endure but stone. An impervious pavement was of special value on a tramway, as it prevented the water sinking alongside the rails.

BRONZE CASTINGS FOR LINCOLN'S MONUMENT.

—A communication from Springfield, Ill., to the *Chicago Times*, gives the following particulars of the bronze groups for the pedestal of the Lincoln monument: It has already been reported that the two bronze groups designed to ornament the base of the National Lincoln monument have arrived here, and that they are to be placed in position at once. These two groups were designed by Larkin G. Meade, of Florence, Italy, who is also the architect of the monument, and who designed the statue of Lincoln, already described. The groups were cast in bronze by the Chicopee Arms Company, of Massachusetts, and are said to be the most elaborate bronze castings ever executed in this country. They are now on the monument grounds, and have been so far stripped of their casings that a comparatively good view is to be had of them, and a really excellent idea of the spirit of the composition is obtained. They have already been inspected by many members of the General Assembly and by hundreds of our citizens.

PARIS WORLD'S FAIR.—The buildings for the Paris exhibition of 1878, says *Engineering*, are growing rapidly. On the Champ de Mars the foundations are laid. The angle pavilions, which are of masonry and 50 feet high, are ready for the iron domes that are to cover them; and the walls of the central gallery, which is likewise of masonry, and intended for the fine arts exhibition, are almost finished. The piers of the rest of the building are ready for the superstructure of iron and glass. On the Trocadero, in spite of the great difficulty of laying the foundations on the hill undermined by quarry-galleries, the two elliptical wings are built, the substructures of the great towers are laid, and the masonry of the central rotunda is finished. Two thousand men were employed upon the works; and up to the 1st of April 1,800,000 francs had been expended upon excavation and masonry; covering 158,000 cubic meters of excavation, 30,000 cubic meters of concrete foundation and 35,000 cubic meters of masonry. Six miles of pipes and sewers had been laid.

A METALLIC DROP CURTAIN.—Voss, Mutter & Co., of Berlin, are fitting a new metallic fire-proof curtain to the theater in Dresden, now rebuilding after destruction by fire. It is of corrugated iron. Exposed to heat a brisk circulation of air is set up in the sections of tubes formed by the corrugations, the heated particles ascending and colder particles flowing in to supply their place. The latter keep down the temperature so completely that a sweating breaks out in the plate of which the curtain, or shutter, as it is, strictly speaking, is composed. The shutter made for the Dresden theater is 40 feet high and 46 feet wide. The method of riveting the plates of which it is composed, and of raising and lowering it, are the subjects of patents.

BELT PULLEYS.—Mr. P. Jansen has devised a way of casting belt pulleys in parts so as to avoid the strains in the metal due to contraction and cost of turning. The rim is cast in a suitable mold of yielding non-chilling substance, but smooth and true, and the boss and spokes are cast in another mold. Afterwards the two parts are united by placing the rim on a face-plate and the boss on a mandril concentric thereto, and then pouring metal into a mold made upon the meeting parts of the spokes and rim, the metal joining the rim and spokes by suitable projections cast on the rim and cavities in the ends of the spokes.

SCIENTIFIC PROGRESS.

Monads.

An exceedingly interesting discussion on these minute forms of life was lately given in London by Dr. W. H. Dallinger, whose researches have been noted from time to time. He gave the results of his observations made during the last six years with high microscopic power on monads. Ten years ago he saw the need of such work in its bearing on the questions of spontaneous generation. No life history of any of these minute forms of life had been worked out; the experiments conducted by those who wrote on the subject relied on high temperatures to destroy organisms in the fluids they examined. After four years spent in preparation he commenced his work in conjunction with Dr. Drysdale, the plan needing two observers. A characteristic feature of the work was that each set of observations should be made absolutely continuously, so that nothing should have to be inferred. An arrangement was made by which the little drop of septic fluid containing the objects under examination should be free from evaporation, and very high powers were employed. The largest adult objects included in the examination were the one-thousandth of an inch, and the smallest adults were the four-thousandth. Six forms altogether were selected, and, by long, patient and unbroken watching, their whole history was worked out. While reproduction by fission seemed at first to the observers to be the usual method, prolonged research made known that spores were produced. These were so small that a magnifying power of 5,000 diameters was needed to see them as they began to grow. The glairy fluid from which they developed seemed at first homogeneous, and it was only when growth set in that the spores became visible. All that could be learned about the origin of the glairy fluid was that a monad, larger than usual, and with a granulated aspect towards the flagellate end, would seize on one in the ordinary condition. The two would swim about together till the larger absorbed the smaller, and the two were fused together. A motionless spheroidal glossy speck was then all that could be seen. This speck was found to be a sac, and after remaining still for ten to thirty-six hours it burst, and the glairy homogeneous fluid flowed out. The young spores that came into view in this were watched through to adult condition. Bearing on the subject of spontaneous generation, this fact was learned, that while a temperature of 140° Fah. was sufficient to cause the death of adults, the spores were able to grow even after having been heated to 300° Fah. for ten minutes. Can it be philosophical, Mr. Dallinger asked, with the life history of bacteria still unknown, to assume it has a different method of propagation? Some experiments based on Prof. Tyndall's use of the electric beam to test typically pure air were made. The remains of infusions known to contain certain spores were diffused through glass tubes, in which were placed vessels with fluid. Adult monads always appeared in the fluids, but when, after the air in the tubes had been allowed to purify itself by settlement, fresh fluids were introduced, no monads appeared. That there is no such thing as spontaneous generation of monads seems quite clear, and when bacteria are in like manner studied, there can be hardly a doubt the same law will be found to hold good with them.

"Growth" of Minerals.

The Mineralogical Society of Great Britain and Ireland is a new organization, but it finds itself abreast of a vexing problem thus soon. We read in English reports that at the last meeting there was a good sprinkling of scientific gentlemen present as visitors to hear Mr. Readwin read his promised paper "On Mineral Growth at Ordinary Temperatures, under Ordinary Conditions." This was a rather lengthy proceeding, but the novel interest was fully kept up by the continuous handing round of about 100 out of 500 at hand of gold specimens by way of proof positive of the truth of the proposition he enunciated.

There has been going on lately a correspondence in the *Chemical News* touching the growth of copper, silver and gold by the aid of heat, steam, hydrogen, etc., at a temperature as low as 300° Cent. Mr. Readwin looks on coolly, as if he should say, "Gentlemen, do not trouble yourselves; I can show you goings-on like yours, brought about somehow by the aid of hydrogen, steam, or heat, or anything else that I know of." This spontaneous "growth," as he half facetiously calls it, with the authentic stamp he seems to put upon it, if true—as Mr. Hutchings, one of the visitors said—really opens up an entirely new field of investigation, touching what Mr. Readwin alludes to in his paper—"Mineral formations in Relation to Time."

The lecturer said that about this time last year, at Aberdeen, he pointed out to Prof. Nicol palpable gold-growths in the museum of his University, and that within the last 24 hours only he had done the same to Mr. Moore, the courteous curator of the Liverpool Free Museum in the collection of that Institute.

After reading and speaking in explanation for nearly three hours to as attentive an audience as he could wish to have, Mr. Readwin wound up by telling of two interesting gold-

growths, which he said he was sure would be easily remembered—one was an angular fragment of auriferous quartz which had got buried in the palm of a miner's right hand after a "scattering shot" at a mine in Wales as long ago as 1846. He said that it was given to him by the miner himself in 1863, and that now there is gold-growth upon it, and it certainly looks like it under the microscope. The other fact was a gold shawl-pin, in which was set, by Hancock, in 1856, a bit of gold quartz from Dolfrwynog. This also has unmistakably grown, he says, and become partially curly, and a skeptic is obliged to acknowledge that it looks like it.

In addition to the reports we read that comment is reserved because more is to be heard of the subject from headquarters. Perhaps this means that some one is going to step upon Mr. Readwin and his theory of mineral growth.

Recent "Remains" in Santa Barbara County.

The *Santa Barbara Press* of April 21st, had an account of digging for "prehistoric" remains at Westminster. Large numbers of human bones were found and also a plentiful supply of bottles. Col. Otis made the philosophic observation, that the "curiosity hunters have simply struck a big graveyard of the native population whom the missionary *padres* found and taught here 80 or 100 years ago, and that they have been digging up the bones of the grandfathers and grandmothers of native people now living among us; or else that the glass beads and bottles found in these uncovered graves were obtained by the natives from Spanish navigators who traded along these shores in the time of Cabrillo and before. In either case the "prehistoric" character of the remains seems to be an extremely attenuated theory."

This position is approved by the following letter from the Pacific coast historian, Bancroft, which was read at the meeting of the Society of Natural History in Santa Barbara last week. It is in response to an inquiry addressed to Mr. Bancroft asking his opinion as to the supposed prehistoric character of the human remains, implements, etc., recently dug up in Carpinteria. The letter is as follows:

DEAR SIR:—Absence from the city is the cause of the delay in answering your very interesting letter. There is no evidence whatever in California of a race older or more civilized than that found by Europeans a century or so ago. In Mexico and Central America the case is very different. There are a few material remains in Northern Mexico, Arizona and New Mexico, but nothing, so far as I have been able to discover, north of these points. Very sincerely, H. H. BANCROFT, May 23d, 1877.

CHEMISTRY OF METEORS.—In a recent lecture Dr. Gladstone, an English scientific man, made these points: The shooting stars, which sometimes appear in showers, no doubt enter our atmosphere from the planetary spaces, and are believed to be connected with the orbits of comets. They seem to be very small pieces of solid matter, which are ignited by rapid compression of the air during their transit, and are dissipated into powder before they fall to the earth. There are, however, larger meteors, which, after their course through the sky, are seen to burst into pieces, often with a loud report, leaving a luminous track behind them. Similar appearances have sometimes been accompanied by the fall of stones from the sky, either singly or in many fragments, strewn over several miles of country. In ancient times these stones were often the objects of worship; now they are collected in our museums. In the finest collection, that of the British museum, there are masses varying from rough powder to a stone weighing three and one-half tons. They always covered with a crust, due to the melting or oxidizing effect of their rapid passage through the air. In chemical composition they show great differences, and while no new elements have been found in them, the arrangement of the constituents is different from that of terrestrial minerals. Some are metallic, principally iron and nickel, others are crystalline rock, consisting mainly of silicates of magnesium, but the large majority of these stones comprised both these species. The most curious points in the composition of some—such as the occurrence of monosulphide of chromium (Daubreilite), and hydro-carbons, were brought forward and described.

GEOLOGY AND THE DIAMOND DRILL.—Famous as is the sub-Wealden boring in the annals of English geology, the interest in it is for a while eclipsed by another deep bore carried on in the heart of London. The object of the new bore is purely commercial, but the scientific results of the operation are carefully noted and preserved for geologists' use. The intention is to sink a well for the use of a large brewery on Tottenham Court road. At 150 feet the clays and gravels were passed and the upper chalk began; from 490 to 812 feet the work lay through hard lower chalk and marl; at 840 feet gault; at 1,004 feet, "greensand," which is a solid stone. The work is done with a diamond drill. One crown of diamonds has cut 400 feet; but the strata have proved of very varied hardness, and the flints in the chalk have occasionally delayed the speed of the work, though not wholly stopping it. When there are no mishaps the progress is 14 or 15 feet per day. The value of the diamond crown of the boring tool is about \$500. Since the above was written advices have been received, stating that water was struck below the greensand and the flow was abundant.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

THE GOOD HOPE.—Amador Dispatch, June 2: The company who recently bonded the Good Hope mine, near the edge of town, have gone to work in good earnest to develop the mine and ascertain its real extent and value. The work is being prosecuted without cessation both day and night.

CRUSHING.—The Kearsling mill commenced crushing rock from the Evans mine last Wednesday night. Also the Onida mill commenced crushing Monterichard rock this (Friday) morning.

MODOC.—Amador Ledger, June 2: J. C. Ham has purchased one-half of this ledge. At present work is confined to running a tunnel to tap the lead at a greater depth. Two shifts at work night and day. The Modoc has yielded some excellent rock, and the quality seems to improve as sinking progresses. Three crushings have been made, the last two giving much better averages than the first. One of the owners tells us that the ore so far has surrendered 827, 840 and 887 to the ton.

PIONEER.—This mine is located near Mace's mill above Volcano. The Irving Brothers and Richard Stoken last summer discovered two small veins of quartz close to, or upon the Pioneer ledge, and which they have been operating at intervals ever since, and from which they have taken considerable money. There is now a dispute about the ownership of the ground.

MERK CLAIM.—The new quartz claim just opened up by Nevill & Co., near the Coney mine, about half a mile outside Jackson, is looking well. The shaft is down over 30 feet, and the ledge at the bottom shows three feet in width. The material is good, and the prospects are bright. The shaft is being worked by the Kearsling mill was started on the ore on Tuesday, and we are told the gold already shows well on the plates.

BUTTE.

MINING ON THE FEATHER.—Oroville Mercury, June 2: Within two miles of Oroville, there are more preparations going on for mining in Feather river than we ever knew before. The new mining machine of Hedge & Co. is working a complete revolution in the business of river mining. The grand trouble heretofore has been to get rid of the water. With this machine the water is wanted and a dozen or even 25 feet of it does not hinder or delay the work a particle. It can go on by day or by night. No windings in the way, nothing to interfere with the successful working of the machine. One of them is now at work on the claim of Col. I. C. Logan and W. S. Higgins, just below town, and is taking up gold at a rate only known to the owners themselves at the present time. Another, and a larger one, is being built up the river and will be ready to go to work by the last of June. This is to be used on Hedge's claim just above Feather river bridge, where it is claimed the bed of the river is very rich in gold. The Main Feather River company are to commence the construction of still another to be used on the old Cape claim, which they now own. This will be begun in a few days and pushed as rapidly as possible to completion. Of the richness of this claim there is no doubt in the minds of those who saw it when opened years ago. We may therefore expect to see three of these machines at work on our river, nearly in front of town, in less than six weeks.

BIG BAR.—From the Secretary of the Big Bar company we learn that work has been suspended on account of the lack of water. During ordinary seasons there would be an abundance of water except perhaps two months in the year. But this year with no snow in the mountains, the supply has been reduced to such an extent, not enough to carry the rocks through the sluices, and the company thought best to shut down until fall. The claim was purchased last January and put in running order, being completely fitted up with pipe, flumes, and two immense chutes, and it has paid well. Already parties on the look-out for paying claims are bidding for this, but as it is mostly owned in town, we hope it will not be sold. It is one of the best places for property in this State. **DUNSMITH.**—Cor. Butte Record: Our mines are second to none in the State. In addition to the extensive operations of the Spring Valley company, Ed. Davis & Co. have, within the last year, completed a ditch costing \$80,000, and they are now working one of the best paying mines in California. Mr. Vinton is working a large force of men on St. Clair flat. Mr. Beard is mining on an extensive scale north of the town. The Flat Valley company have established a mill within three miles of town, and are doing an immense business in lumber.

CALAVERAS.

TIGER.—Calaveras Chronicle, June 2: An immense ledge has been uncovered in the Tiger mine at Rich Gulch flat. A cross-cut has been run 14 feet without reaching the hanging wall, and no one knows how wide the ledge is. The ore is low grade, but there is such an immense body of it that \$5 rock can be made to pay handsomely.

THE RAIN.—One of the heaviest rain-storms of the season visited us this week. Rain commenced falling early Monday morning and continued, almost without intermission, until Tuesday evening. In the neighborhood of two inches of rain fell. Miners generally speaking the rain was a blessing, and the physiologists of miners and ditch men are corrugated with smiles. There is now a ditch full of water, and as considerable snow fell in the mountains, the water supply will continue several weeks later than the most sanguine had hoped. The consequence will be to extend hydraulic operations well into the summer.

Snow.—Considerable snow fell in the vicinity of Blue mountain last Tuesday night, and at a greater altitude it is said to have been unusually heavy.

SHILL RILL.—The remarkably rich rock struck in the Gwin mine several weeks since still continues, and the indications are favorable that it will be found the entire length of the level. The whole ledge, outside of the exceptionally rich streak, is composed of first grade ore, and we learn that the yield of the mine is largely increased. The Gwin is now certainly entitled to rank first among the mines of the coast, and its yield is greater to-day than that of any other quartz mine in California.

UPPER COUNTRY MINING ITEMS.—Intelligence from the upper country is of the most encouraging character. We are informed that the mining interest is in the most flourishing condition, and that the times are livelier in West Point than they have been for three years. Splendid rock continues to be taken from the Chamouni mine. There are 50 tons of first grade ore now on the dumps and about 100 tons of second grade. Crushing will be commenced next week. The crushing of ore from the Granite mine, in the Josephine mill, is about concluded. We understand that the company to whom the mine is bonded is much pleased with the result of the crushing and will undoubtedly be purchasing the property. Splendid rock has been obtained from the Anderson Flat and Woodhouse mines, and the probabilities are that sales will be made to San Francisco companies in both instances. The new Zacateno mill is about completed. The engine and the other appurtenances are on the ground, and it is expected to have the battery running next week. Any amount of rock is in readiness for crushing as soon as the mill is completed. Fields & Co. have run a tunnel over 400 feet on their ledge, obtaining good rock the entire distance—one of the longest pay chutes in the county. The Mina Rica is looking splendidly, the immensely rich ore mentioned last week evidently being a permanent attribute of the mine. At Railroad times are brisk. Sunderland & Co. have out about 800 tons of rock. We understand that they have leased Clark's mill and will commence crushing shortly. It is their intention to keep the battery constantly employed this summer, and we have no doubt but that they will be able to do so. Potter & Co., at Mos-

quito, are still mining surprisingly rich rock from the "Blue Jay." They are down 100 feet and the mine is making a most excellent showing.

INYO.

MINER NEAR UK.—Coro Mining News, June 2: Among the valuable mines near Darwin there are none more deserving of special notice than the Chattanooga, American and Silver Fort. We made a trip over to the Chattanooga and the other mines mentioned a few days ago, and although within seven miles of Darwin, we had no idea that such prospects were to be seen. Passing down the Darwin Wash trail, near to the first springs, we go up a trail leading from the "Wash" to the summit of the Argus range, lying between this place and Panamint valley, and upon the eastern side we find the Chattanooga, from which a large number of sacks of the best ore ever found in Inyo county has been taken out and now awaits shipment. This ore assays all the way from \$80 to \$250 per ton, being free-milling, with no lead whatever. The ledge is not wide, but the croppings, visible for a long distance, indicate that all that is requisite to establish a permanent and paying vein is deeper sinking thereupon. Their workings at present consist of two or three cuts run in upon the ledge from the east side of the hill, in every instance striking the ledge. The ledge lies between granite and limestone. There are several other mines in this same hill which show nearly as well as the Chattanooga, and in due time will receive the attention they deserve. We next went to the Silver Fort and found two men at work sinking an incline upon the ledge, and although looking well at a depth of 30 feet, to which the shaft has been sunk, it is not yet deep enough to indicate correctly of the mine. The mine is cropping true waste and character of the ore, however, lead us to believe that deeper exploitation will develop a most valuable mine. The ore from this mine is free-milling, in fact is impregnated all through with horn silver and rich black and grey chlorides. The fact that this mine is within a mile or so of springs of sufficient capacity to run an 80-stamp mill makes it all the more valuable. Ore from the mine can be delivered at a point where the mill might be located for not to exceed 75 cents or \$1 per ton. We predict that before another year has passed one or two mills will be industriously at work upon ore to be extracted from the mines in this particular vicinity.

NEVADA.

EMPIRE.—Grass Valley Union, June 5: This mine has quite a history. It is situated on what is known as the Ophir Hill ledge. The location was made in 1850, by George D. Roberts. In 1851 Roberts sold to Woodbury, Park and others, and in 1852 that firm failed and the property was sold at auction. John R. Rush purchased one-half of it and the Empire Mining company the other half. In May, 1855, Rush sold his half interest to the Empire company for the sum of \$12,000. During all the changes work on the mine was kept up. The mine has been more than once on the point of shutting down, and underground appearances have caused the trustees frequently to consider the propriety of quitting work. Whenever, however, the pumps were ordered to be taken out and the machinery housed up in silence, the ledge delivered a new and sudden richness and more strength, which caused sudden countermanding of the orders to stop. The Empire mine in that matter seems to have been a sentient thing. The mine is skillfully and economically managed by David Watt, Superintendent, and he is ably seconded by James Bennelack, Underground Foreman. For a long time the returns from the Empire have been uniformly good, and the oldest working mine in the State has been a constant source of wealth. A man-up made for last Saturday gave about \$16,000 in gold, not including sulphurets, for a 20 days' run of the mill.

THE IDAHO shows no material change. Yesterday the trustees met and declared the 94th dividend of \$7.50 per share of capital stock. This gives \$28,250 for the month just past.

SHALL VALLEY NEW.—The hoisting works have been in running order for several weeks. The contractors for sinking the old shaft, which was 60 feet in depth, have got down 23 feet, making present depth of shaft 83 feet. The ledge in the bottom of the shaft 18 inches on one side and 12 inches on the other.

BULL-DOZER.—This valuable mine, located some months ago by Judd and Hearsch, still continues to send out \$150 rock.

BUFFALO.—This property is situated north of Cincinnati flat, and is owned by J. W. Peters & Co. A crushing was had four loads of ore a few days ago, and the result was \$80 worth of gold, or \$20 worth to the load. The owners are going to put on eight hour shifts and do constant work. The mine looks promising.

INKERMAN.—On Lafayette hill, located in 1854, and near the North Star mine. For many years it yielded no rock was done up to it to hold the property, but that work showed most excellent quartz—much of it being beautiful specimens. It is now owned by Oakland capitalists and is being developed with satisfactory results.

HOMEWARD BOUND.—Located in 1854. It is in an excellent quartz region. The machinery has been lately removed to the new and permanent shaft, and the pump was started up yesterday. A common rumor had it, a few days ago, that the Omaha had shut down. The rumor was not true. The Superintendent pulled up 120 feet of pumps, and prospecting will proceed in the upper levels to the north of the shaft, to find a pay chute.

ALASKA.—Is running full handed, and is taking out and milling ore that is paying well and profitably, and, at the same time, is sinking the shaft ahead with a view of opening up other levels.

KENTUCKY RIDGE MINE.—On the tunnel level the west drift is down 185 feet and the east drift 125 feet—the ledge being from 18 to 21 inches in width, and prospects well throughout. The building and machinery for an eight stamp mill is now on the ground, ready to be put up. It is expected that the mill will be completed early in July. It will be run by water power, by a ditch from Deer creek. A contract has been let for building a dam across Deer creek and constructing the ditch. The dam will be 13 feet in height, the ditch 24 feet in width and two feet in depth, and 260 rods in length. The mill will be run by an overshot wheel 304 feet in diameter and will be capable of running 20 stamps. When the mill is ready to start, a compressor will be put up, and two Ingersoll drills set to work for the speedy completion of the second, or lower tunnel level.

NEW YORK HILL.—The main incline is being sunk for the 9th level. The company intend putting in a compressor and power drills, and are only waiting to decide which is the best to adopt. Ore is taken out of the 6th and 7th levels in sufficient quantity to keep stamps and 40 men are doing regular day work in the mine, and 35 men are engaged to do contract work—driving the 8th level, sinking winzes, etc. The mine is looking well, is paying expenses, and with the opening of the 8th and 9th levels, dividends are confidently anticipated. The mine is superintended by George Johnson.

PITTSBURG.—The 7th level north of the shaft has been driven in 187 feet, and is in fine body of ore. The work, commenced several weeks ago, and shows a fine ledge all the way. Over 100 tons of rock is now being crushed from this portion of the mine, which shows a yield of \$30 per ton. An air compressor has been put in, and power drills (the National) have been set in the stopes between the 6th and 7th levels. By the last of this week two of these drills will be started on the 6th and 7th levels north of the 7th to the 8th level. It is thought the shaft can be put down to the 8th level in six weeks. Tribute rock is being taken from the levels south of the shaft, but the main development of the mine is being made to the north of the shaft, where a rich pay chute is found down to the 7th level, which has a northerly pitch on the course of the vein. The same chute will be out on the 8th level, and will give extensive beds of high grade ore.

LAFAYETTE NO. 2.—Is the southerly extension of the original Lafayette, on Osborn hill. The latter claim has, in years past, yielded ore which milled \$40 to \$150 per ton. The deepest workings on the ledge attain a depth of

only about 70 feet. Usually 50 feet reaches water in such quantity as to render the aid of machinery imperative. Machinery has never been employed. The company owning Lafayette No. 2 will proceed at once to run a tunnel at such a place as will enable them to cut their ledge at a point which will give them about 120 feet of backs. This will be the greatest depth, by 60 feet, yet reached on the ledge.

LOWELL HILL GRAVEL MINES.—The Swamp Angel mine near Lowell hill is working away with grand success. The ground is worked by drifting and is paying better than any drift mine in the State, the sum of \$30 a day to each hand being realized. The Planet, adjoining the above and on the same ledge, is having a tunnel driven direct for the place in the channel where splendid pay gravel was found in the old tunnel—the old tunnel being too high for successful work. The Planet company own 240 acres on the ledge. The ground has been thoroughly prospected through the mine and is known to be rich. The contractors who are running the tunnel have known the ground for years and they take a good portion of their pay in stock of the company. In the winter the Centennial has again struck the pay chute, and are taking out more of that rich rock. A crushing at John Smith's Orleans mill is now going on. They began crushing last Saturday. Dillon has all the machinery up and will start up about Thursday of next week. Pacific, of New York hill, is paying well, averaging about \$110 to the load. The "Couch" is about 3,000 pounds. Hughes McGuire & Co., adjoining the Pacific, on New York hill, are taking out fine ore that will pay well.

SUGAR LOAF.—Nevada Gazette, June 2: Frank Guld is sinking on a ledge next to the road leading to Sugar Loaf. The rock from this ledge is rich, and, if thoroughly worked, will undoubtedly develop into a good mine. Henry Randol and Wm. Sloan are prospecting a quartz ledge at Coyote hill. They have an incline down 40 feet. The ledge varies from two to 12 inches in width. It shows well in free gold and carries sulphurets and galena. Captain Connor has caused work on the North Banner and taken up the machinery used there. We hear it said that the ledge will not be abandoned, but, when worked again, heavier machinery will be required.

PLACER.

ANOTHER BONANZA.—Placer Herald, June 2: Beside the bonanza struck by A. O. Bell, as mentioned by us on former occasions, he has another ledge near Bald hill, from which he is taking out much as much as the pay chute. Some parties have put a string of sluice-boxes in Red ravine, about a mile below town, and are washing out some old ground that was mined over in early days.

The Big Gun hydraulic mine, owned by the Van Emom brothers at Michigan bluff, has been able to get in only about 20 or 25 days' run this season, though for the time they have done well.

MILBERRY & CO., the purchasers of the Dardanelles and Oroville hydraulic claims, near Forest hill, have closed down for the season, and express themselves, we understand, as very well satisfied with the results. They propose putting on a force of men for the purpose of running a hydraulic tunnel and fitting up their claims generally for the next season.

BEECE & WICKLER., owners of the famous hydraulic claim at Bath, have shut down for the season after a run of 55 days of 10 hours each, from which they realized about \$40,000. With their large four-foot flumes, put in last year, and steep grade, they are enabled to run off very large boulders, which enables them to work the claim at much less cost than formerly.

Most of the hydraulic claims on the north side of the Forest Hill divide, near Smith's Point, Brushy canyon and Yankee Jim's, are reported to us as having had a reasonably fair season's run. Most of them have now shut down.

SHERIFF & LAWLER, whom we mentioned recently as having realized over \$130 per ton from a small crushing of rock taken from a ledge recently discovered by them about a mile north of Auburn, continue to find most encouraging prospects. They have made a thorough examination of the ledge for about 200 feet along the surface, and find it two feet wide and rich for the whole distance. About 150 feet from their main shaft they have sunk another about nine feet deep, and find the rock the same as in the first shaft, very rich in galena and free gold.

MR. WILLIAM TAYLOR, who has been working for some time on the Taylor & Gwynn mine, about a mile south of Auburn, near Bloomer ranch, has just completed a whim for hoisting purposes. He is now down about 60 feet, has a ledge two feet wide and growing wider as he sinks, and has never sunk a foot, it is said, without taking out rock that showed free gold.

THE STORM.—Dutch Flat Forum, May 31: Our miners have again been made glad by an unusually heavy storm for this time of year, which we are informed has deposited about 18 inches of snow on the mountains above us. This will extend the winter season beyond the expectations of the most sanguine, our mines are all washing about the same as last reported, and the time has not yet come for their monthly clean-ups.

SHADY RILL.—Hydraulic still progresses in the Wild Yankee; and from the large amount of gold that is seen in cleaning bedrock, the results from the next general clean-up is expected to be very large. The North American is again the scene of activity, the force of men having been increased and the dirt now being extracted is said to be paying large dividends.

REMINOTON HILL.—Ground sluicing continues to be the leading feature in the Rhode Island, the results from which as usual pay well. The Wide West company have added several improvements to the working of their mine, consisting of a large water tank, dirt dump, new sluices and box. Both tunnels are being advanced rapidly; the gravel tank is being extended to the very rich ore. The drift that was opened east of tunnel No. 2 was found to be too high for practical working, another is being opened on a lower grade, and the gravel they are passing through it is said will pay large dividends.

LOWELL HILL.—The Swamp Angel mine was never in a more prosperous condition, there being a large amount of ground opened up ready for breasting out, all of which will pay good dividends. This company declared another dividend last week.

LIBERTY HILL.—The Liberty Hill company are washing with two streams, and considering the amount of boulders they have to contend with, are making good progress.

YOU BET.—Washing in the Nees & West is progressing without interruption. The Walopoa, last week, after a very fair season of 10 hours each, cleaned up and shut down for the season. The Nevada company are still washing from four points, which they expect to be able to continue until September. The Hussey company made their final clean-up last week, resulting in the obtaining of five or six thousand dollars in amalgam.

SIERRA. **BETTER AND BETTER.**—Mountain Messenger, June 2: The Swallow company, of Monte Cristo, have declared a dividend for May—four weeks working time—of \$145 to the interest, \$100 more than that for the preceding month. The gross yield was \$2,135. This is over 22 cents interest for that time, each dollar invested. The boys declare they will keep it up next month.

BELL'S BAR.—A company of gentlemen from Forest City and San Juan have taken up a claim on Middle Feather river, in Plumas county, and will commence work immediately. They have a splendid prospect of striking the real blue lead, which can be traced about nine miles to Nelson Point.

P. H. CHASER.—A gentleman has bought an interest in the Swallow claim, Monte Cristo, which he intends working.

SNOW.—It is reported that about two and one-half feet of snow fell at Gold Lake during the storm, and about 18 inches at Rattlesnake.

CHUNKS OF GOLD as large as your hand have been taken out of the Bald Mountain claim this week, at Forest City. The last clean-up here was larger than any heretofore.

Some more rich discoveries were made this week, near Forest City.

There was a cave in an air course in the Bald Mountain this week, which it took three days to repair.

TRINITY.

CLOSED FOR THE SEASON.—Trinity Journal, June 2: J. G. Trotter informs us that this week will end piling, and work in the Union Hill claim will be closed for the season. The claim was in a terribly bad condition when Trotter took hold of it last year, but is now in a condition for making a splendid winter's work next year. The slide den top, which checked work a year ago, has been moved up to solid earth all around, and the course of the pay streak for over 200 feet in width exposed. The claim now shows heavier "wash" than ever before, and every miner knows that to be a good indication.

CHANGED HANDS.—The claims at Point Bar, with the ditch, carrying water thereon from Foker, or Tom Lang's ditch, was sold this week to Mr. J. C. Wallace. We are informed that it is the design of that gentleman to bring the ditch along on a higher grade from Murphy's Flat, and extend it to the claims of Hughes & Wallace, opposite Garden Bar. The proposed re-survey also gives a better pressure to work the Point Bar claims.

TUOLUMNE.

THE MOUNTAIN MINES.—Union Democrat, June 2: A correspondent, who has been rambling through the mining region in and about Summerville, informs us that Mr. Reuben and partner, who are working a re-location of the great Eastern mine, have struck the pay chute of the ledge at the south end of this level, having connected \$23 per ton. This mine is situated above the on unstocked ranch, and in early days was worked by the Nalls Brothers with good results, the rock at that time paying from \$70 to \$100 per ton. The pay chute was lost and the mine abandoned by the original locators, lying idle until within a year ago, when it was re-located by Mr. Brooks and partner, who, in cleaning out the debris, struck the lost lead. The present enterprise in re-opening an arastra on the mine, and have several tons of good ore on the dump, which will be worked by this process as soon as the arastra is completed. The work of extracting the ore continues.

Nevada.

WASHOE DISTRICT.

CONSOLIDATED VIRGINIA.—Gold Hill News, June 6: Daily yield, 500 tons. The various ore breasts through out the mine are looking well and yielding finely. Especially is this the case at the 1650-ft level, where the great ore body being breasted out is all of high average grade. The drift south of this level having connected with the deep winze, it is being trimmed out and enlarged to allow of the best possible passage for the air. This connection allows of good ventilation, and has cooled off that portion of the mine considerably. The broken crank shaft at the Consolidated mill will be replaced by a new one in a day or two, when the mill will be run to its full capacity as before.

YELP.—The east drift of the 2200-ft level is in 85 feet to-day, and still continues in regular vein matter, consisting principally of hard bird's-eye porphyry, with occasional small streaks of quartz. Little or no water is encountered. The lateral drift south at the same level, following the ore vein, is also in 85 feet, and, during the past few days, has been passing through quite a number of streaks of quartz, giving promise of ore development. The drift south of this level, which is now in 85 feet. In fact, this level, which is 750 feet below the level of the Suro tunnel, is as dry thus far as could be wished.

JUSTICE.—Daily yield, 450 tons. This quantity, however, will be increased as soon as preparations to that effect are completed. On the first of the present month a transfer of the milling of the ores from this mine was made to the Union mill company, and to-day the hauling of the ore by the Overman street car to the Virginia and Truckee railroad was commenced for transportation to the mills of the company, on the Carson river. The mine is looking, at present, better than ever before in its history. Plenty of good milling ore is in sight in the upper working levels, the winze below the 800-ft level continues in fine ore, the face of the main drift south at the 1000-ft level shows more and more improvement in the quality of the complete drift advance, and the main drift east at the 1100-ft level is running very favorable vein material.

CALIFORNIA.—Daily yield, 500 tons. The mine is looking exceedingly well, and the various ore sections are yielding handsomely, as usual. The winzes sunk below the 1600-ft level are making good progress, and the bottoms of each are in rich ore. The foundations for the large new air compressor are being pushed forward to completion, and other preparations are being made to secure better ventilation to the lower levels through the C. & C. shaft.

NEW YORK.—The third compartment to the shaft has been completed, and timbered throughout, from top to bottom, in a workmanlike manner, and this shaft is now one of the best in the State. The pump tank stations are cut out, and the pump is ready to be put in whenever required.

LADY WASHINGTON.—Arrangements are now being made to open and work this mine through the 1150-ft level of the Justice. This will be an important as well as economical move, as it will open the mine at a considerable depth below the present lowest workings.

LEVATHAN.—The face of the south drift at the 600-ft level is now nearly all in ore of a fair milling grade, which shows constant improvement in both quantity and quality further up the level.

OVERMAN.—The south drift, at the 1100-ft level, is pushing ahead in very favorable vein material, carrying occasional streaks and bunches of ore.

SURO TUNNEL.—The header is now passing through vein material, which works easy, allowing of much better progress than heretofore. This tunnel having now reached the vicinity of the Comstock, might have been in ore body at almost any time. Total length of tunnel to-day, 17,947 feet.

UTAH.—The drift eastward at the 1100-ft level, cross-cutting the ledge at that point, reached the east wall yesterday morning, and a drift south has been started from it to explore the ledge in that direction. This cross-drift shows the ledge to be over 100 feet wide. It is simply a huge, solid, well defined vein of solid quartz, showing no impure opportunity for finding some in drifting either south or north.

CHOLLAR-POTOSI.—Daily yield a little over 100 tons. Average assays, \$25. Total yield for May, \$43,550. The old ore sections hold out well.

IMPERIAL CON.—The south winze below the 2185-ft level is making good progress downward, and is passing through quite a number of rich ore breasts.

CALIFORNIA.—To-day the sum to the shaft is being completed below the 1600-ft level. Will open a station at once and start a drift west for the ledge at that level.

GOULD & CURRY.—The V bob for the heavy pump has arrived, and as soon as practicable the pump will be put into working condition.

JULY.—The cross-cut west from near the south end of the 1300-ft level is steadily advancing and shows constant improvement, assays yesterday averaging \$13 to the ton.

UNION CON.—At the 1300-ft level the drift north is steadily advancing, and showing constant improvement in the character of the vein matter encountered, more and more quartz making its appearance.

PROSPECT.—Work is suspended at present in order to make room for the new machinery.

BLANCHER.—Daily yield, 75 tons. Prospecting at the 1000 and 1600-ft levels goes forward as usual.

CROWN POINT.—There is no decrease in the flow of hot water from the face of the east drift or cross-cut at the 2000-ft level, and the heat makes it almost impossible to work there. The prospects are very good, however, for a development of some kind.

OUTA.—Daily yield, 40 tons. At the 1900-ft station the station timbers are put in and a sump is being completed and as soon as a water tank can be cut out and the pump lowered a drift will be started to open out the 1900-ft level.

BEST & BLANCHER.—Good work is being done on all prospecting points, and the machinery operates finely.

MEXICO.—The north drift at the 1462-ft level is run-

THE ENGINEER.

A Monument on the Sand.

It is perhaps well that the Washington monument, which has been the mortification of the people ever since it was begun, has not been completed.

The commission heretofore appointed to examine into the sufficiency of the foundation of the Washington monument, consisting of Lieutenant-Colonel Kurtz, Duane and Gilmore, submit their reports as follows: First. That the stratum of sand and clay upon which the monument rests is already loaded to the limit of prudence, if not, indeed, to the limit of safety, and that it does not offer sufficient resistance to compression to justify completion of the shaft in accordance with the modified design or any other design that will load the underlying soil beyond 10,000 pounds per square foot. Second. That the additional weight imposed at the top of the structure will, in all probability, cause additional and probably extensive spilling and splitting in the ashlar facing near the base. Third. It is evident that the masonry foundation was not given spread enough to carry safely the weight it was designed to place upon it. If sufficient spread and depth had been originally provided, the full height of the structure might have been placed upon it, and the weight distributed over a larger area, so as to be within the limits of security. Fourth. There has been an actual compression of the soil to the extent of between eight and nine inches; the shaft is sensibly out of plumb, and the foundations show an increasing departure from horizontality. The imperfections may be expected to increase as additions are made to the weight of the structure, if not to a dangerous degree, at least to an extent that will make the monument very unsuited to the purpose for which it was designed. If it were a tower, or shaft, or chimney, intended for manufacturing or industrial uses, such defects might be overlooked and useful results still expected from it. But this structure is to be an exposition to the world of the estimate which is placed upon Washington by his countrymen. It is a great bare obelisk, plain to severity—a conception, perhaps, most suitable to symbolize the great character it would commemorate, but for these very reasons exacting in all its parts and particularly in all its foundations. The stones which compose the foundation should be strong and perfect, and truly shaped and accurately placed together. There should be no yielding of the parts and no disturbance of the levels. Upon such a foundation a monument could be reared fit to commemorate Washington, and worthy of the nation of whose foundation he was the chief master-builder.

Life in the N. P. R. R. Enterprise.

From reports in the *Railway World* we learn that the North Pacific railway enterprise shows some hopeful signs of life. It has gained possession of that portion of the St. Paul and Pacific between Watab and Brainerd, which was to shorten the distance from St. Paul to Bismarck, on the Missouri river, and to Manitoba, in the Canadian Dominion, 100 miles. The unfinished interval was 64 miles long. It was mostly graded, partly tied and bridged. The Holland bondholders, who financially controlled the property, refused to advance more money. The N. P. R. R. Company agree to finish the road in August, and have Northern Pacific trains running into St. Paul.

The *Railway World* remarks further that the stockholders of the company had a most satisfactory surprise at their recent meeting, in that, instead of being confronted by a directorial scheme to raise money to build and equip the company's branch to coal, they were met with a resolution adopted by the board the day previous, that the revenues of the road had so increased, and were so increasing, as to suffice for the completion of the branch, and to make a resort to mortgage unnecessary.

The reorganized Northern Pacific Railroad Company has astonishing life and promise. It has, within four months, nearly completed 31 miles of road to an 11-foot vein of the best bituminous coal. Both divisions of the road earn a surplus; a largely increased area of its lands have been put into "No. 1 spring" wheat, and the promise of traffic from this source this year is great. The country on the line of the road in Minnesota and Dakota is rapidly settling with farmers.

A corporate meeting, which began with resolving to keep out of debt, fitly closed by the stockholders instructing the directors to devise and present to them, at a future meeting, a plan to raise means to extend the road west of the Missouri river into Montana Territory.

RAPID BORING.—A remarkable example of rapidity in deep boring has recently been furnished by the first bore hole put down by a company formed to search for coal in Switzerland. A depth of 1,422 feet was reached in two months, including the re boring of the upper 640 feet from three and one-half inches to seven inches in diameter. The work was done, including all delays, at a rate of over 1,000 feet per month, the highest speed being nearly 77 feet in 24 hours. The results obtained were negative, the section showing about 1,200 feet of Permian strata resting upon old crystalline rocks, but the trial is only the first of a series.

The New Bergen Tunnel.

The new tunnel through Bergen hill, back of Jersey City, was formally opened on May 12th, about three and one-half years from the first beginning of work. In 1873 there were excavated 690 linear feet; in 1874, 2,922 feet; and in January, 1876, the tunnel was finally opened through its whole length. By this time, however, it had been found that the rock was less solid than had been supposed, more friable and likely to fall, and it was necessary to arch the tunnel for the greater part of its length. This work has been thoroughly done, but it necessarily took much time.

The tunnel has two tracks and is 27 feet wide and 4,219 feet in length, exclusive of the heavy stone arched portals, 35 feet long at one end and 25 at the other, making a total length of 4,279 feet, or 100 feet shorter than the Erie tunnel. The shafts are seven in number, giving light and ventilation. Nos. 3 and 4 shafts are the full width of the tunnel, and all are surmounted by a brick wall rising to a height of 16 feet above the surface and open on top so that the smoke may freely escape.

It was at first designed to have an open cut at shaft No. 4, which is about midway, to the extent of 300 feet; but this idea was abandoned, and there was constructed instead a large shaft, 27 by 18 feet. Here a signal station may be placed, so that two trains may be run in the same direction at one time, thus doubling the capacity of the tunnel.

The masonry in the side walls is two feet thick and 10½ feet in height. This is surmounted by a brick arch 22 inches thick, covered with felt and asphaltum where there is a chance of water leakage. The space between this and the rock is filled with broken stone and concrete. The arching is carried three-fourths of the length of the tunnel, the remainder being a solid mass of rock, so that no apprehensions may be felt in regard to the falling of fragments of rock. A better idea of the extent of the tunnel may be formed from the fact that 94,000 cubic yards of rock and 76,000 cubic yards of earth were excavated therefrom. In arching the tunnel 10,000 cubic yards of rock and 5,000,000 brick were laid. The track is of 68-pound steel rail, and the ballast consists of broken stone. The trap-rock was found to be difficult to drill, but easy to fracture.

Improvements of the Mississippi.

Captain Eads has achieved such signal success with his engineering dentistry in the mouths of the Mississippi, that he now proposes to doctor the upper portions of the river. He has matured a plan which is a practical application of his jetty theory, to the entire extent of the river to Cairo, and we suppose also to St. Louis. It is to reduce the width of the river, making the entire body of water pass through one channel, which, by the increased velocity, scours out the sediment formed as it becomes wider and the velocity of the current correspondingly weakened. The work at the jetties has increased the depth of the South Pass from eight to twenty-two feet, and the depth is still increasing. This plan, if applied to the full length of the river, would supersede the necessity of the levee system, for this regimen would keep the river in its banks at flood height, and the rich alluvium of the valley would be saved from overflow without levees. The estimated cost of the levees is \$44,000,000, and even when made they are liable to break in high floods or to cave off, leaving large districts exposed. We have heard no estimate of the cost of Captain Eads's proposed work, but have no idea it would reach near this vast sum.

The *St. Louis Journal of Commerce*, from which we take the above facts, remarks further that there is nothing to prevent the establishment of a permanent channel of twenty or twenty-five feet depth from the City of St. Louis to the mouth of the river. And now that the jetties have secured that depth to all the outer markets of the world, there is no reason why ocean steamers with that draft should not ascend the river and discharge cargoes from all parts of the world, and load again with Western produce and manufactured articles to supply their varied wants. But in place of this we have the miserable condition that for not more than four months in the year does there exist an assured depth of ten feet in very many places from here to the Balize. The result is that much that is produced, unable to bear the high rates of rail carriage, does not go to market, and the inducements to increased production are destroyed.

THE OTHER SIDE OF THE PICTURE.—The *Deadwood Times*, pitying the condition of the thousands of tender-feet who do not know a mine from a mill-site, but rush into a new gold district with barely money enough to get there, under the delusion that they will find gold lying around loose, tells the following tale of misery: "Our city physician reports a considerable number of immigrants sick in their cabins. There are too many men coming to the Hills with barely enough money to bring them here, and the result is they become sick from exposure and destitution. The bulk of those who come in this way to the Hills know nothing of mining, and necessarily are in a bad way. The sooner men can be made to understand that mining to succeed must be systematically prosecuted the same as any other business, and is more precarious than farming or merchandising, and requires an investment of capital, the better they will be off."

The Rights of Aliens to Mining Property in the United States.

A Supreme Court Decision.

We condense the following from the detailed decision of the Supreme Court of Nevada, in the case of the Ruby Consolidated mining company (limited) appellant, vs. Hermann Heynemann, et als, respondents. The case is a very important one, but the decision is unfortunate for the encouragement of foreign capital in our mines. We have commented on this point in another column of this issue:

"It was admitted in open court by counsel for plaintiff and defendants that, at the time of the commencement of this action, the plaintiff was and is a corporation, organized under the laws of Great Britain, and not a citizen of the United States, and that it never had declared its intentions to become such. Plaintiff thereupon offered to establish by testimony all the allegations in the complaint herein, and defendants thereupon objected to such or any evidence, on the ground that the plaintiff, not being a citizen of the United States, nor having declared its intention to become such, and being a foreign corporation and an alien, cannot enforce the contracts or trust set forth in said complaint, and that the same is contrary to public policy and to the laws of Congress relating to the public mineral lands; and the court sustained such objections and refused to allow plaintiff to introduce any evidence or testimony, to which ruling and decision counsel for plaintiff then and there excepted." Whereupon the court denied the injunction and dismissed the application.

The appeal from the order of the District Court consequently involves but one question: Whether, taking the allegations contained in the complaint to be true, they show a *prima facie* right in an alien corporation to the injunction prayed for.

The complaint is extremely voluminous, but for the purposes of this opinion a brief statement of the substance and effect of the allegations affecting the defendants, Heynemann and Plater, will be sufficient.

It is charged that in August, 1872, the defendant, Heynemann, claiming to be the owner of various unpatented mining claims in Eureka (then a part of Lander) county in this State, in consideration of the insurance to him of certain shares of paid-up stock of the plaintiff, contracted in writing to sell said claims to plaintiff free and clear from any charge or incumbrance whatever, and further agreed to give to said company free and undisturbed, and actual possession of the same, and to use his best endeavors to promote the interest of the company in working said mines.

That Heynemann then agreed to hold said mines in trust for the plaintiff and to manage, develop and work them as its agent. That as such trustee and agent he took possession of the mines and held them for a long time for the plaintiff, and while so holding them expended \$30,000 of plaintiff's money in their development and in the purchase of adverse and conflicting locations.

It is further alleged "that shortly after said Heynemann became the trustee of said plaintiff, as aforesaid, he represented to the plaintiff that it was important that patents should be obtained from the United States Government for said lands, mines and mining lands by him sold to the plaintiff, and that until the patents should be issued everything would have to be done in his name, as being the ostensible owner of said property, and agreed to and with the plaintiff to take all necessary legal proceedings to obtain the same, and employed surveyors, counsel learned in the law and others for that purpose at the cost of the plaintiff," etc. That afterwards he did obtain patents in his own name for various of said mines, which patents are now in his possession and under his control. That plaintiff had entrusted the management of its business and the care of its interests in Nevada entirely to Heynemann, reposing the fullest confidence in his integrity and good faith. That, while so trusted, he had been guilty of many acts of duplicity and fraud; and, in particular, he and the defendant Plater, who was employed under Heynemann in the working and management of the mines, and was receiving compensation therefor from the plaintiff, availing themselves of the opportunities afforded by such employment to ascertain the situation of the best ore deposits, entered into a conspiracy to defraud the plaintiff of its most valuable mine. That, in pursuance of such fraudulent conspiracy, Plater, with the connivance of Heynemann, made a location called the "Atlas," covering the better part of the "Dunderberg"—one of the claims sold by Heynemann to plaintiff. That Plater then applied for and obtained from the United States a patent for the ground embraced in said "Atlas" location, and now holds the same under a secret understanding that it is to be shared with Heynemann. It is alleged that plaintiff was deprived of all opportunity of contesting Plater's application for said patent by the fraudulent practices and concealment of its agents, Heynemann and Plater.

It is further alleged that said Heynemann and Plater have converted to their own use large sums of money arising from the net product of the Dunderberg and other mines of the plaintiff. That they are now extracting val-

uable ores from said mines. That, notwithstanding plaintiff has issued to Heynemann and his nominees the shares of its capital stock which it agreed to issue to him in consideration of the sale of said mines, and done everything on its part to be done to entitle it to a conveyance, Heynemann refuses to convey. That there is danger that he and Plater will imperil plaintiff's rights by conveying to third parties, and that, in various ways, plaintiff may be irreparably damaged if the defendants are not restrained.

The prayer of the complaint is that the defendants may be decreed to be trustees of the plaintiff and compelled to convey said mines to plaintiff, and to account for the ores extracted therefrom, for a perpetual injunction and for general relief. Pending the litigation, plaintiff asks for a receiver and for a temporary injunction. The order of the District Court, denying such temporary injunction, is the subject of this appeal.

The defendants, in their several answers to the complaint, by denials and the allegation of new matter, contravert most of its material charges. But, for the sake of argument, it is agreed that they shall be considered true, defendants contending that the plaintiff is, nevertheless, entitled to no relief, for the reason that "the contract declared on and the trust sought to be enforced are invalid as contrary to law, and void as opposed to public policy, as declared by the paramount law of the land."

The "paramount law" here referred to is that established by the several acts of Congress relating to the disposition of the public mineral lands. According to counsel for respondents: "The United States, the absolute owner of the mineral domain, in disposing thereof has seen fit to select certain classes as the donees of its bounty, and to prescribe when, how and by whom, and upon what conditions and limitations this bounty may be enjoyed. In so legislating it declared a policy and a purpose, binding of course upon all courts, without any regard to its wisdom or expediency. The statute enacts that the land is declared to be free and open to exploration, occupation and purchase by citizens and those who have declared their intention to become such. Thus citizens, and citizens only (leaving out here and hereafter, to avoid repetition, the other class), may occupy or obtain a patent; they and they alone shall have the 'right of possession and enjoyment.' Express power is given to alienate the title to others than citizens after the patent is obtained, the implication on the maxim *expressio unius* being that before patent obtained they cannot convey to an alien."

Counsel for appellant says: "The act of Congress of July 26th, 1866, which granted the mineral lands belonging to the United States unto those who explored and occupied them, limited such grant to citizens of the United States only, and thereby excluded aliens from the right to enjoy the same or to receive a patent therefor, but did not prevent aliens from purchasing said lands from those who, as citizens, had lawfully received a patent for them."

So far as these propositions agree, there can be no doubt that they express the true construction of the law and to this extent they clearly agree: that an alien is incapable of acquiring any right to occupy or enjoy the mineral lands so long as the title remains in the United States, and consequently that he can never become entitled to apply for, and can never obtain a patent for such lands. This brings us to the most important question involved in this appeal: Was the contract declared on an attempted evasion of the law of Congress? Would its enforcement be to set the law at naught?

The position of plaintiff is that the contract was in no manner opposed to or evasive of the laws of Congress, and that, since the mining lands in controversy have been patented, since the Federal Government has parted with its title to citizens of Nevada, the rights of the United States are no longer involved, and the laws of Congress no longer applicable in the decision of the controversy between these parties, whose rights, it is said, now depend exclusively upon the common law respecting aliens, which has been adopted in this State without any unfavorable alteration.

Counsel have not been able to produce any decision upholding the right of an alien to enforce specific performance of such a contract.

Upon the whole it is, to say the least, very doubtful whether, if Heynemann had held the Government title to these mines when he contracted to sell them to the plaintiff, a specific performance could be decreed, except at the suit of and for the benefit of the State. The character of that contract was not such as counsel for plaintiff seek to attribute to it. It was not an agreement on the part of Heynemann to convey the mines in question after he should receive the Government title, but an agreement to convey them on receipt of certain shares of plaintiff's capital stock. The arrangement under which he continued to hold the property, "as the responsible owner," for the purpose of obtaining the patents, was an afterthought, and was entered into for the express purpose of accomplishing a forbidden object, viz: To enable the alien corporation to obtain, through him, the Government title, and, in the meantime, to occupy and enjoy the mines under the cloak of his pretended ownership. This is substantially and in effect what the complaint says, though it would make no material

A Practical Miner's Suggestions.

An old practical miner of Eureka district, who is a close observer, gives the following sensible suggestions in the *Sentinel*: The query, "why not help ourselves," is a subject for the business portion of our community to digest. Eureka as a mining camp is one of the best, if not the best on the coast. Its past record shows this; its future is in the hands of the people. Who is to be credited with making Eureka a number one mining camp? The resident population or outsiders? How many are in this town who have really done anything to develop or bring the mines of this district to a paying basis? The number is very small. When our business men, men of money, have money to invest in mining they almost invariably seek investment in some outside stocks, when they should, if they studied their own interest, invest something at home. Ruby hill has heretofore kept up the whole community. It has enriched its owners, besides giving employment to thousands of laborers; but the treasures of Ruby hill are locked up in litigation, and may remain so for several months. What has the people to fall back on to keep the place up in the interval? The truth is, they should do something to help themselves. The business men of Eureka say it is out of their line of business to engage directly or indirectly in mining. The question is: Is Eureka likely to keep up a first-class mining camp unless there are new developments made? Outside capital has made Eureka what it is or has been. Is outside capital likely to come to our rescue the second time? It is hardly likely that it will unless some new developments in our mines are made. It is generally believed that there is rich mining ground enough in this district outside of Ruby hill to keep up a larger community than there is in the district. Why not do something, then, to open new mines, so as to give employment to the idle population, by reason of the shutting down of the mines of Ruby hill? Who is to do this? Why, the merchant, the hotel-keeper, the saloon-keeper, men of all trades must take hold and help themselves; do something to help open new mines, and not be dependent on Ruby hill alone. When they do this, they will find that by helping to keep up the mining interests they lay the foundation for a good legitimate business in trade, and not before. By helping themselves they help others, or by helping others they help themselves.

Oregon Minerals.

The total product of mines worked in the counties of Jackson and Josephine, in southern Oregon, since 1851, when gold was first discovered, is estimated at upwards of \$18,000,000. Baker and Grant counties in eastern Oregon have also yielded many millions. On the ocean beach near Coos bay, placer mines have been worked to a considerable extent. Rich gold quartz leads have been partially worked in the southern part of the Cascade mountains. Lead and copper have been found in large quantities in Jackson, Josephine and Douglas counties. Large deposits of rich iron ore exist in nearly every part of the State. The mine at Oswego, on the Willamette river, about six miles south of Portland is the most extensive so far developed. Coal abounds in nearly all portions of the State. Extensive beds exist on Coos bay, in Douglas county and on the northern Umpqua. Partially explored beds have been discovered on Yaquina bay, at Port Orford near St. Helens, and at different points in Clackamas, Clatsop and Tillamook counties. The Coos bay coal ranks very high in the San Francisco market. The want of invested capital has retarded operations, but Oregon is coming to the front and the day is not far distant when our mines will attract the attention they deserve.—*Oregon Mining-Immigration Journal*.

Increase of Shares.

The increase of shares in the Comstock mines since 1870 is thus indicated by the Bulletin:			
Mine.	1870.	1877.	Increase.
Sierra Nevada, shares.....	15,000	100,000	85,000
Union Consolidated.....	10,000	100,000	90,000
Mexican.....	10,000	100,000	90,000

COLORADO CENTRAL EXTENSION.—Captain Berthoud has completed the survey of the extension of the Colorado Central from Longmont, Colorado, to Cheyenne. Work will be begun at once and pushed to completion. The distance is less than 75 miles, the grade easy, and the road can be built at small cost. The road will pass through as good country as there is in the west for the first 50 miles from Longmont to Box Elder.

USEFUL INFORMATION.

Staining Metals.

This valuable specialty in artificers' work is made the subject of an article in the *American Art Journal*. The following practical hints are given:

Metals may be colored quickly and cheaply by forming on their surface a coating of a thin film of sulphide. In five minutes brass articles may be coated with any color, varying from gold to copper-red, then to carmine, dark-red, and from light aniline-blue to a blue-white, like sulphide of lead, and at last a reddish-white, according to the thickness of the coat, which depends on the length of time the metal remains in the solution used. The colors possess a very good luster, and if the articles to be colored have been previously thoroughly cleaned by means of acids and alkalis, they adhere so firmly that they may be operated upon by the polishing steel. To prepare the solution, dissolve one-half ounce of hyposulphite of soda in one pound of water, and add one-half ounce of acetate of lead dissolved in half pound of water. When this clear solution is heated to from 190° to 200° Fah., it decomposes slowly, and precipitates sulphide of lead in brown flakes. If metal be now present, a part of the sulphide of lead is deposited thereon, and, according to the thickness of the deposited sulphide of lead, the above colors are produced. To produce an even coloring, the articles must be evenly heated. Iron treated with this solution takes a steel-blue color; zinc, a brown color; in the case of copper objects, the first gold color does not appear; lead and zinc are entirely indifferent. If, instead of the acetate of lead, an equal weight of sulphuric acid is added to the hyposulphite of soda, and the process carried on as before, the brass is covered with a very beautiful red, which is followed by a green (which is not in the first scale of colors), and changes finally to a splendid brown with green and red iris glitter. This last is a very durable coating, and may find special attention in the manufactures, especially as some of the others are not very permanent. Very beautiful marble designs can be produced by using a lead solution, thickened with gum tragacanth on brass which has been heated to 210° Fah., and is afterwards treated by the usual solution of sulphide of lead. The solution may be used several times.

Progress in Silk Manufactures.

A correct notion of the state of the silk manufacturing interest in this country may be gathered from the report which was presented to the Silk Association of America at the annual meeting this spring by Franklin Allen, the Secretary. The total manufactures of silk for the past year are valued at \$26,593,103, the items which run into the millions being tram, \$2,768,490; organzine, \$1,614,961; machine twist, \$6,301,059; millinery and the silks, \$1,679,166; dress goods, \$1,350,535; ribbons, \$4,526,556; ladies' dress, \$3,705,076. The report states that on the whole last year's business was very unsatisfactory, though the raw silk consumed in manufacture was within 150,000 pounds of the largest amount used in any previous year. This unsatisfactory condition is ascribed to the great rise in the price of the raw material, amounting on the average to 100 per cent.; to the pressure brought to bear on our markets for goods by foreign manufacturers who had injured their markets abroad by excessive adulteration, in some cases reaching more than three-fold the weight of the silk; a pressure which became a crisis at Lyons and caused the surplus goods there to be thrown on this market, thus keeping the price of goods here comparatively low, while the price of the raw material was rising; and to the great extent of frauds by undervaluation at the Custom-house. The estimate of loss to the revenue from the last-named cause alone is put at \$4,000,000. Goods are sold here, "duty paid," at about the same price as they bear at the place of export without duties. The report suggests that the honest foreign manufacturers' interest and those of American manufacturers and honest merchants coincide. At the same time it does not recommend the substitution of specific duties, or of a mixed tariff, but the continuance of the present simple ad valorem rate of 60 per cent., which is sufficient if the present laws are thoroughly enforced.

REFINING MINERAL OILS.—Two Scotch inventors have devised a method of refining mineral oils in which the use of the sulphuric acid and subsequent washing with caustic soda, heretofore used and found very expensive, are dispensed with. And the nature and novelty of the invention consist primarily in the employment of sulphurous acid (instead of sulphuric acid) either in a gaseous or liquid state. The crude oils are received or placed in the ordinary refining cistern, tanks, or troughs, where they are washed with sulphurous acid gas, which immediately precipitates the tarry matter and other impurities in a much superior manner to that experienced with sulphuric acid. The sulphurous acid is preferred to be used in the liquid state, and is introduced amongst the oil gradually in such quantity or for such period as experience determines for the particular quality or kind of oil under treatment, the washing being continued until the tarry matter and other

impurities are precipitated and the pure oil left floating above, which, so far purified, is then run off into other vessels and again washed with sulphurous acid and water until the impurities are fairly removed. The oil is then finally refined in the usual manner, except that the use of caustic soda in quantity is not required in the washing process as heretofore when sulphuric acid was used in the refining process. Hitherto the tarry matter obtained or produced in oil refining has been considered as waste by reason of the vitriol contained in it, but the tarry matter resulting from the present process being free from vitriol may be utilized for various purposes.

A NEW USE FOR SAND.—The incompressibility of sand is suggested to the *American Journal of Industry* as a cheap and ready means of making supporting columns and bases for anvils, or for blocks designed to support heavy weights. Sand inclosed in thin wooden or iron walls, if thoroughly shaken down, may be made to sustain a much greater weight than the walls or cylinders alone, by placing all the weight directly on the sand and quite free from the walls that retain it. Wooden boxes filled with sand thus make excellent supports for anvils or tables for laboratory work. So long as the pressure is vertical, the sand will sustain far greater weights and resist heavier blows than could be borne by solid blocks of wood of the same size.

TESTING PETROLEUM LUBRICATING OILS.—There are few persons who can detect a worthless oil even among a number of good samples, but a few simple tests will aid a novice somewhat in this particular: First, require a bright green color; second, brilliancy of appearance when dropped upon a piece of clear glass, or as shown by throwing the oil up upon the side of a clear sample bottle containing it is indicative of purity; third, see that no precipitation is made in the bottom of a sample bottle or jar of whatever color; black, white or red. As oil is the best known lubricant for general use, avoid a mixture of it with foreign matter, whatever the claim.

CLOSING DOORS WITH COMPRESSED AIR.—The *Polytechnic Review* translates the following from a French authority: A. M. Pelletier has made a novel application of compressed air—namely, for closing doors. The doors are connected by means of an iron or caoutchouc tube surmounted by a ball at each end. When one door is opened, the series of levers act upon the rubber ball, compress it, and necessarily the air contained therein, which dilates the ball at the other end and by a series of levers similar to the first, closes the other door, and vice versa.

TO PREVENT STEEL FROM OXIDIZING DURING TEMPERING.—Small articles in steel are said to be preserved from rust while being tempered by giving them a coating of ferro-cyanide of potassium. For this, two parts of finely-powdered charcoal and one part of ferro-cyanide of potassium are boiled up to a thick paste with a solution of gelatine or strong glue. After warming them, the articles are dipped into this mass, dried, dipped again, and so on, until the coating is the twelfth of an inch thick. The articles can then be exposed to a coal fire, heated to redness, and tempered without fear of rusting.

GOOD HEALTH.

Clean Hair.

A lady says in the *Western Stock Journal*: No matter what our work is, the dust will gather upon the hair. With housekeepers this can be largely prevented by wearing something over the hair while sweeping or working where there is dust in the atmosphere. A cap made of cambric is as good as anything to wear, and may be made in this wise: Take a square of cambric of the usual width (three-quarters of a yard), cut from it as large a circle as possible, turn a hem an inch and a half in width all around, stitch it down, and outside this make another row of stitching, leaving a space of one-fourth of an inch between the two; into this space run a piece of elastic cord, and draw up until it is the right size for your head. Such a cap is easily made, looks well, will fit over your hair in whatever manner it is dressed, and will thoroughly protect it from dust. However, if dust does, and it will, collect upon the hair, it can sometimes be removed by brushing, but always by washing, provided we wash it properly. Never use soap—it leaves the hair stiff and unmanageable. The same is true of ammonia. Use the yolk of an egg, and in this way: Beat the yolk of an egg in a teacup, fill the cup with tepid water, let down the hair, shake it out well, and pour on a little of the egg and water, rubbing the head briskly meantime; repeat the process until the whole is used. If not enough to wet the hair thoroughly and to make a good lather, use more water on the head. After rubbing well, rinse the hair well with tepid water, applying a little cold water at the last. Dry it as well as possible with towels, and if it is long let it remain down upon the shoulders until quite dry. There is no danger of taking cold from this process if ordinary care is used. For children who are in school and often come

home with something in their heads, which you think is scarcely an idea, yet is certainly an enemy, a wash with ammonia and water will destroy both parasites and their larvæ. Use 10 or 15 drops of ammonia in a tumbler of water, and apply it in the same manner as directed for washing with egg. If anything is cruel, it is to take a little curly head between your knees upon a pillow and rake it through and through with a fine-toothed comb until the little scalp is red and bleeding. Try the ammonia cure, and the children will rise up and call you blessed.

POISONOUS CANDY.—The *Boston Herald* says: "The City Board of Health has, after considerable effort, succeeded in bringing five cases of adulteration of candy before the criminal courts, which the prosecution hope will stand the test of law and evidence, and result in the punishment of the persons accused and the deterring of others in the same business from using unwholesome ingredients. Within a few months quite a large number of specimens of candy have been subjected to analysis, and the trash found only shows that to the ordinary purchaser at random, candy is a good deal like Mark Twain's hash—a mystery. Only five of the cases, however, proved to be so strong as to convince the Board that convictions could be had, and in these the evidence was presented to the Grand Jury. Bills were found and yesterday William F. Schaffe, William Schnetzer, George Fera, William F. Stahl and S. Herbert Chase were arrested, brought into the Superior Criminal Court and gave bail in \$600 each for their appearance for trial. The material portions of the indictment are substantially as follows: 'That the defendant unlawfully and fraudulently did adulterate a certain substance, to-wit: one pound of confectionery, with a certain substance injurious to health, to-wit: with a certain substance called chromate of lead.' The second count charges the adulteration 'with a certain substance injurious to health, the name of which, and a more particular description of which is to the jurors unknown.' The indictment is drawn under chapter 106, section three of the Revised Statutes."

RECREATION.—The literal meaning of this word is to make over again; but in its ordinary acceptation it is intended to convey the idea of rest, refreshment, or rather, renovation. The body is refreshed by rest; the brain is renovated by sleep, by absolute repose. But both brain and body may be invigorated for a season by changing the direction of their respective activities, and also by working alternately. A man who has become tired of riding on horseback or in a carriage, rests himself, gets rid of his fatigue, by walking. The brain which has become weary in thinking of one subject is refreshed by taking up some other study. On the other hand, a man who feels tired all over, by work or a long walk, will get "rested" sooner by sitting down to read than if he did nothing. Rachel, the great tragic actress, when returned from one of her performances, at two or three o'clock in the morning, rested herself by spending an hour or two in changing the furniture of her rooms. The best sedative which a public speaker can take after a great effort, is to read a newspaper or anything else which has a variety of short statements. The great practical idea we wish to convey is that recreation is not idleness, but a change of direction in the operation of the physical or mental forces. A French actress lately went mad within an hour after the play, because she went home, laid down, and let her mind run on in the same track. She should have changed to bodily activity, like Rachel.—*Hall's Journal*.

LEMON-JUICE IN CARBUNCLE.—The *Doctor* says: "Dr. Gibbons, having been a sufferer from carbuncle, relates in his admirable journal his own case, in which lemon-juice seemed to have a most beneficial effect. Wine, whisky, tonics, and all the usual remedies gave him no relief, and did not help digestion. As soon as he took lemon-juice digestion improved, as well as the local symptoms; and the effect was such that he intends to treat his patients in the same way. He also thinks blue pill frequently useful. We have found in other diseases lemon-juice a most grateful remedy, especially where (as Dr. Gibbons mentions in his own case) there is a desire for acid drinks and vegetables."

FOREIGN BODIES IN THE NOSE.—Parents are often puzzled to help their children when they get beans, buttons, etc., in their noses. The *Medical Record* says: Blow the patient's nose for him, by closing the empty nostril with your finger and blowing suddenly and strongly into the mouth—an efficient method which has often succeeded when instruments have failed. The glottis closes spasmodically, and the whole force of your breath goes to expel the button or bean, which commonly flies out at the first effort.

VENTILATING CHAMBERS.—When it is considered that pure air is essential to the purification of the blood, and that the food we eat never becomes nutriment until it meets with the air in the lungs, and when it is furthermore remembered that a full third of our entire existence is passed in our sleeping apartments, it must be clear to the commonest understanding that the difference between breathing a pure and impure air while we are asleep is literally incalculable as to the effects upon our happiness and well-being.

MINING SCIENTIFIC PRESS

W. B. EWER, SENIOR EDITOR.

DEWEY & CO., Publishers,

A. T. DEWEY, GBO. H. STONG,
W. B. EWER, JNO. L. BONGE.

Office, No. 224 Sansome Street, S. E. Corner
of California Street, San Francisco.

Half inch (1 square).....	\$1.00	\$3.00	7.50	24.00
One inch.....	1.50	4.00	12.00	40.00

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper, inserted at special rates.

Four insertions are rated in a month.
Subscription in ADVANCE—Postage paid—one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by registered letters or P. O. orders at our risk.

SAMPLE COPIES.—Occasionally we send extra copies of this paper to those we believe would be benefited by subscribing to it themselves, or who are willing to hand the paper and speak of its merits to others. We call the attention of such to our prospectus and terms of subscription.

WRITE for the MINING AND SCIENTIFIC PRESS. We invite not only professional men, but practical miners and mechanics to contribute to our columns. All communications will be kindly treated. Authors, as well as readers, will be benefited by corresponding.

Address all letters to the firm, and not to individual members, or others, who may at any time be absent.

Our latest forms go to press on Thursday evening.

SAN FRANCISCO:

Saturday Morning, June 9, 1877.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Davidson's Break Circuit Chronometer; Harris' Patent Lathe Driver, 361. The Head & Sisco Centrifugal Pump, 369.

GENERAL EDITORIALS.—New Break-Circuit Chronometer; Items of Interest From the Mines; Obviating the Use of Numerous Dogs, 361. The Week; Foundry Notes; The Tidal Wave; The Crown Point Mine; Hydraulic Gravel Elevator, 368. Structure of Iron and Steel; Chinese Miners; The Head and Sisco Centrifugal Pump; Trial of a Fire Extinguisher; The New Yellow Jacket Hoisting Works, 369. New Incorporations; Civil Service Reform in the U. S. Patent Office; The Sisco Amalgamating Process; Academy of Sciences; Chloride of Calcium for Street Sprinkling, 372.

CORRESPONDENCE.—Calaveras County Mining Interests; The Hunt, Douglas and Stewart Process; The Mechanics of Pan Amalgamation; Mining in Amador County, 362.

MECHANICAL PROGRESS.—Mixtures for Steel Tempering; A New Style of Steamboat; Puddlers' Plugs; A New Pulverizer; How to Lay Street Railways; Bronze Castings for Lincoln's Monument; Paris World's Fair; A Metallic Drop Curtain; Belt Pulleys, 363.

SCIENTIFIC PROGRESS.—Monads; "Growth" of Minerals; Recent "Remains" in Santa Barbara County; Chemistry of Meteors; Geology and the Diamond Drill, 365.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments, Meetings and Dividends; Review of the Stock Market for the Week, 364.

MINING SUMMARY from the various counties in California, Arizona, Idaho, Montana, Nevada, Oregon and Utah, 365-72.

THE ENGINEER.—A Monument on the Sand; Life in the N. P. R. R. Enterprise; The New Bergen Tunnel; Improvements of the Mississippi, 366.

USEFUL INFORMATION.—Staining Metals; Progress in Silk Manufactures; Refining Mineral Oils; A New Use for Sand, 367.

GOOD HEALTH.—Clean Hair; Poisonous Candy; Recreation, 367.

GENERAL NEWS ITEMS on page 373 and other pages.

MISCELLANEOUS.—The Lead Market, 362. The Rights of Aliens to Mining Property in the United States, 366-70. A Practical Miner's Suggestions; Oregon Minerals; Increase of Shares, 367. Honorary Names in Scientific Nomenclature, 370.

NEW ADVERTISEMENTS.

The Victor Rock Drill, MacDowell, Kinzer & Co., S. F.; Weyrauch—Iron and Steel, John Wiley & Sons, N. Y. Sales—Boo-h Gold Mining Co.; Empire Mining Co. Assessments—Mariposa Land and Mining Company of California; Consolidated Bonanza Gold and Silver Mining Company.

The Week.

Nothing of any special interest in connection with the mining industry has transpired during the week. Stocks are yet dull, and this affects everything more or less. The Comstock, particularly, feels the depression seriously, and many mines, a few months since actively worked, are now idle. The California mines, however, do not seem to feel this pressure to any great extent, and, in many parts of the State, notably Nevada county, the mining interests are in a healthy condition. Mining news from Arizona show good prospects in that Territory, but there are too many poor men there now, and everybody is waiting for capital. Several mills and furnaces have been sent down there of late, and there are two or three mills now being built here which will be sent there on completion. Our readers will notice by what is said in other columns this issue that the manufacture of mining machinery has by no means ceased in the city notwithstanding dull times. The Union Iron Works shipped this week the largest air compressor ever made in the United States, and also some unusually heavy and improved hoisting gear. Our "Mining Summary" gives all the late news from the mines in various districts, States and Territories, and will repay perusal by those interested in our mining developments.

Foundry Notes.

Business among the foundries and machine-shops in this city is extremely dull at present, and there is scarcely any work of any magnitude going on anywhere. The dull times affect large and small shops as well, and most of them are running short-handed, which at this season of the year is very unusual. As a general thing this is a busy time in the season for foundrymen, but the prevailing depression in the mining interests keeps away large orders for mining machinery, which forms a very considerable proportion of the work of the large foundries. At the

Union Iron Works

They are pretty busy and are engaged on the only large mining machinery now being made in the city. They have just finished a new 20-stamp mill, and are building a 10-stamp mill—the latter for Arizona, where they have shipped several within the past few months. They are also making a number of pans and settlers for different localities. Some magnificent machinery is also being shipped for the Yellow Jacket mine, and is of new design in many particulars. This is described in detail in another column of this issue. They are engaged also in shipping the heaviest air compressor ever made in the United States, which is intended for the C. & C. shaft. The steam cylinder of this compressor is 27 inches and the air cylinder 30 inches in diameter; stroke 36 inches. They are connected by a 12-inch shaft. The steam cylinder is furnished with patent drop or poppet valves, and patent expansion gear. The fly wheel is 14 feet in diameter, with a 12-inch face, turned all over in the rim and weighs alone 30,000 pounds. This is an extremely heavy fly wheel and is probably one of the finest turned out in this city. New patterns were made for it and it is being finely finished up. The air and steam cylinders are connected together and bolted to a heavy sole plate 11 feet long, 42 inches wide and three inches thick. The air cylinder is brass lined and fitted with brass inlet and outlet valves and seats. The big fly wheel is made in two pieces and held together by two five-inch bolts in the rim, and four three-inch bolts at the hub. The whole machinery is finely finished, and is a job creditable alike to the firm and the workmen at the

Pacific Iron Works

Business is slack as at other places, although of course some considerable work is being done. They are sending a complete ten-stamp silver mill to Turkey Creek district, Arizona, for the Murat Milling Co. This is to work ore principally for the Goodwin mine, the company owning the mill being largely interested in the mine. There is a fine outfit with this mill, consisting of a White roasting furnace, etc. They are just shipping the last of the machinery for the Hackberry mine, Arizona. This consists of a complete ten-stamp mill with white furnace, etc. They have just shipped from these works a quicksilver furnace of the Eames pattern to the Edith quicksilver mine, Lake county. Considerable machinery is being made for Tuscarora district, Nevada, as they are putting in new pans and settlers, and in fact re-building the Real Del Monte mill, with new batteries etc. The machinery is also being supplied for a new steam tug for Adams & Taylor, to go up the coast. This consists of a direct acting, compound surface condensing engine. The diameter of the high-pressure cylinder is 20 inches and of the low pressure cylinder 36 inches, with 24 inch stroke. The works furnish the steam pump, circulating pump and pipes, etc. In the yard of the works is the machinery for a street-car which is to be worked on a new principle, both steam and compressed air being used. This is a device of Mr. Chas. Stevens, and will be tried on the Mission street road in a few days. It is a "fireless" locomotive, that is, there is a reservoir for holding steam and hot water, which is supplied every trip, but no fire is used under this reservoir. There are new features connected with the device which make it different from anything heretofore used, and we shall give a detailed description of the machinery as soon as the trial comes off.

The Sacramento Boiler Works.

Messrs. Hall & Kelshaw, in Joshua Hendy's building, are at work building a large number of small tanks for a sugar refinery. They inform us that it is probable they will show our citizens what can be done in the way of an iron steam launch on this coast before long. Pressure of business has prevented them from constructing a launch before this but as this excuse no longer exists, they may have one on exhibition at the coming Mechanics Institute fair. There is no reason why these launches should not be built here as well as anywhere else and the proprietors of this shop having had considerable experience in this line, ought to be able to make a first-class one.

Joshua Hendy

Continues to make numbers of the "\$1,000 Challenge ore feeders" and of his concentrators. He has just shipped five of the ore feeders to Deadwood City, Black hills. This is the first machinery that has gone from this coast to the Black hills, all the rest of the mining machinery in use there having been made in the Eastern states. Four of the feeders were also shipped this week, to Briggs Brothers, at Black Hawk, Colorado, and three to S. B. Schrontz, at the

same place; with the last order were shipped, also, two of the Hendy concentrators. Mr. Hendy is also making a number of the Harris patent lathe driver, which is described in another column; this is a California invention which has attracted attention at the East, but instead of being made in the East, as is usual in such cases, they are made here and shipped there. This is the correct way to do, as it sustains home manufactures and gives employment to home mechanics.

The Tidal Wave.

In our issue of May 26th we gave a diagram showing the record of the earthquake waves that were indicated by the tide gauges of the U. S. Coast Survey at Fort Point in this harbor. Since then advices have been received from various points, showing that the waves in some cases caused great damage. In the Hawaiian Islands, according to the *Gazette*, it appears to have occurred simultaneously all over the group, but, as its incipience was at early dawn, it was not observed except in a very few places. At Kahului, on the island of Maui, as stated by a correspondent, the first unusual subsidence of the sea was noticed about a quarter before five in the morning, by parties who were out in the bay fishing. An observer in Honolulu, who was near the harbor and who had his attention attracted by the shouting of the natives, and saw the exposed reefs, places the occurrence at exactly the same time, viz.: fifteen minutes before five. Mr. J. J. Porter, of Hilo, Hawaii, fixes the moment of the wave which overwhelmed the village of Waiskea, at precisely the same time, and the statement of Capt. Smithers, of the whaling bark *Pacific*, which was lying at the time in Hilo bay, corroborates this. According to Mr. Severance, the oscillation of the sea was first remarked about four o'clock in the morning, nearly an hour previous to the great wave. The difference between the highest and lowest water mark at various localities we ascertain to be as follows: Hilo, on the east side of Hawaii, 36 feet; Kealekua bay, on the west side of Hawaii, 30 feet; Kawaihau, west side of Hawaii, 5 feet; Kahului, north side of Maui, 22 feet; Lahaina, south side of Maui, 12 feet; Honolulu, south side of Oahu, 4 feet, 10 inches; Nawiliwili, southeast side of Kauai, 10 feet.

The details of the disaster at Walakea, which was overwhelmed by the wave, are five people drowned, seven people badly injured, 37 dwelling houses entirely destroyed, 17 dwelling houses badly injured, 163 people left destitute without houses. There has been nothing like this wave at the Islands since 1837, when many houses were destroyed.

Advices received via Panama say that Callao was visited by a wave, and considerable damage done. The devastation was known to have extended as far south as the northern boundary of Chile, but how much further is not known, as communication is interrupted. The *Elder* reports the almost complete destruction of Antofagasta, Iquique, Arica, Tambo, Demora, Pabillon de Pica and Ilo. The destruction of life and property was owing entirely to the frightful upheaval and ingress of the sea. A gentleman who arrived by the *Trujillo* states that the flourishing town of Iquique, the principal port for nitrate shipments, is left as complete a ruin now as it was after the frightful earthquake and inundation in 1868. At Arica the sea washed over the town to the heights back of the church, and destroyed much valuable property. The wreck of the United States steamer *Waverer*, which was carried inland a couple of miles by the tidal wave in 1868, was again floated and carried a mile or two further up the coast. The lower part of Antofagasta, which is a part of the celebrated Caracoles mining district in Bolivia, is reported as completely destroyed. The smelting and other works near the shore are reported as all swept away. The shipping at Pabillon de Pica and the guano deposits suffered severely, and some half a dozen fine vessels are reported ashore and completely wrecked. The sea in some places is stated to have risen over sixty feet.

The Crown Point Mine.

The annual election of the Crown Point mining company was held this week, there being considerable excitement on the question as to who was to gain control for the ensuing year. The Sharon-Jones clique gained the day, although the contest was very close. The President, Col. Weller, in his report, said: The present year has unfortunately been a fruitless one for this company, and during a great portion of the time all mining stocks have been greatly depreciated, so that this company's management has undergone the closest, most persistent, and, as I think, quite disingenuous scrutiny. The result has been allegations of mismanagement totally unfounded in fact. It was alleged that there was a discrepancy of 10,000 tons of ore between the report of the Superintendent and the return of the Assessor at Virginia. This was simply the effect of a clerical error. He also denied that outside mills were kept running on Crown Point ore, and cited figures to prove the fact. He declared that no low-grade ore has been worked that has

run the company in debt; but that, on the other hand, they have made money by working such ores.

The Superintendent stated in his report that during the past year 1,150 feet of drifts and crosscuts have been run on the 1700-foot level, developing nothing but low grade ores, assaying from \$2 to \$5 per ton. The main incline has been advanced 577 feet. It has been thoroughly demonstrated that no pay ore exists on the 1700-foot level, and to open a new level, it was deemed best on the score of economy to continue the incline to a depth of 2,000 feet and there open a new level. On this level a distance of 300 feet, through hard blasting ground, was run before the vein was struck. At the time the vein was struck they also tapped a strong flow of water, and they dare not increase this flow of water with their present pumping facilities. The vein, so far as exposed, shows quartz of a good character, giving assays of from \$2 to \$7 per ton. The joint pump shaft is now down 1,950 feet, and at 1,900 feet a new level has been started to tap the ledge. He concludes by saying that the mine has never been in a better condition for the extraction of ore, and all that is needed is that pay ore be found.

The ore statement is as follows: 20,153 tons crushed yielded \$277,584.85, an average of \$13.77 per ton. The bullion yielded \$121,154.72 in gold, and \$155,435.34 in silver. The average cost of working the ore was \$9.11 per ton. The liabilities, June 1st, 1877, were \$71,846, and the assets \$463,462.

In the Secretary's report it was shown that the receipts of the company for the year were from six assessments, \$525,314.80; sale of bullion, \$277,584.85; overdrafts, \$129,153.27; other sources, \$17,201.26. Total, \$943,254.18.

This mine has since 1861 paid \$11,664,000 in dividends, and levied assessments amounting to \$1,373,400, showing a profit to stockholders of \$10,290,600. The mine has had a varied history, being at one time the lowest priced in the Stock Board, and again the highest priced.

Hydraulic Gravel Elevator.

We saw this week, at the shop of Joshua Hendy, a little machine for use in gravel mines, which in certain instances would be the means of saving a large amount of time and money. It is intended to be used in such places as the gravel is required to be raised a short distance to obtain fall, the object being accomplished as the gravel is passing along down the sluice, without the need of any expensive gear or additional expense to speak of. It would be extremely useful in such a case as where miners started a bedrock tunnel and found that after they got in the bedrock pitched deep or the tunnel was started too low to tap the gravel. In such cases the work has to be done over again, and when it is remembered that such undertakings cost from twenty to one hundred thousand dollars, it will be seen that anything likely to overcome such difficulties is exceedingly useful. With this little apparatus an incline could be run down and the tunnel continued along. At the low point this appliance can be set and the gravel raised up to the proper height, when it can flow off.

The thing consists of a pipe which is placed in the flume or sluice with another pipe coming into it at an angle so that a head of water in the branch pipe forces the gravel, etc., up the required height. It is claimed that 200 feet head will raise the gravel 30 feet; moreover, this additional water is not wasted, as it may, after it has done its duty of raising the gravel, be run back into the flume and assist in washing the dirt. One of these machines was tried some time since at Fiddletown, where it elevated the gravel thirty feet, but work on the mine was discontinued before the appliance became much known, as the dirt did not pay in the mine. A full working model is being set up at Mr. Hendy's, where it will soon be in operation raising gravel a few feet.

BULLION SHIPMENTS.—Since our last issue shipments of bullion from prominent mines have been as follows: Grand Prize, May 27th, \$6,967.41; Tybo Con., 28th, \$12,694; total to date, \$79,568.04; Northern Belle, 29th, \$12,791.44; California, 31st, \$270,716.04; total to date; 1,306,295.85; Con. Virginia, 31st, \$211,652.01; total to date, \$674,042.64; Grand Prize, 31st, 7,200, June 2d, \$196,396.86; total to date for May, \$1,562,692.71; Con. Virginia, June 2d, \$54,171.36; total to date, \$728,214; Modoc, May 31st, \$6,179.20; total for May, \$95,827.65; Chollar, June 2d, 9 bars, value, \$23,241.31; total for month, \$43,550.16; Empire, June 1st, \$15,000; Standard, June 1st, \$20,329; total for May account, \$50,999; Grand Prize, 5th, \$9,500.

MECHANICS' INSTITUTE.—At the annual election of the Mechanics' Institute, held on Monday, there was but one ticket in the field, and the following gentlemen were chosen Trustees for the ensuing year: P. B. Cornwall, Henry S. Smith, H. L. Hutchinson, Ernest L. Ransome, A. L. Fish, Columbus Waterhouse, and James Duffy. One half of the Board of Trustees of the Institute is chosen each year, to serve two years. The full Board is therefore composed now of the above named gentlemen and the following, who hold over from last year: A. S. Halliday, H. L. Davis, George Spaulding, Asa R. Wells, J. B. Stetson, James Drury and James Spiers.

Structure of Iron and Steel.

We have received from John Wiley & Sons, 15 Astor Place, N. Y., a copy of Weyrauch's "Strength and Determination of the Dimensions of Structures of Iron and Steel," with reference to the latest investigations. This is an elementary appendix to all text books upon iron and steel constructions by Dr. Weyrauch, Professor in the Polytechnic school at Stuttgart, and has been translated by A. Jay DuBois, Professor of Civil and Mechanical Engineering, Lehigh University, Pennsylvania. The work also contains an appendix by Robt. H. Thurston, Professor of Mechanical Engineering in the Stevens Institute of Technology. The author states in the book that the present English translation of his work has been kindly made by Prof. DuBois at his special request, and that by the courtesy of the publishers, John Wiley & Sons, he receives a liberal copyright therefrom. No other English translation has been or will be authorized by him.

This work is a very important one and should attract particular attention at the present time when there is so much discussion on the subject of the strength of metal in bridges. The methods of calculation of the forces which act upon the various members of our bridges and other structures have within the past ten years, owing to the united labor of European and American engineers, gained remarkably in clearness and reliability. These advances can however, as Prof. Weyrauch very truly says, attain their greatest value only when the question as to what forces these members can sustain with the desired degree of security, is satisfactorily disposed of. The present work gives a systematic presentation of a new method of dimensioning based upon two formulae deduced by Prof. Launhardt and Prof. Weyrauch. This method, while simple, gives considerable economy of material as well as increased security, while the ordinary methods of statical calculation in general use remain unaffected by it. As the resistance of riveted constructions depends directly on the quality of the rivet connections, great attention is given by the author to this hitherto neglected subject. In order to make the work serviceable to the practical engineer, the author has subjected the numerous experiments upon the strength properties of iron and steel recently made in various countries to careful comparison and scrutiny and thus has given a concise representation of the present state of knowledge in this respect. Everything is there given, which, after the completion of the statical calculation, may be desired.

No one interested in constructions involving the use of iron and steel can afford to ignore the results set forth in this work. As the translator in his preface says, we have to do here, not with the results of theoretical reasoning itself based upon assumptions more or less questionable, but with legitimate deductions from the results of varied and careful experiments. It is but justice to American engineering to state that its best representatives have already long accepted and made use of these results. The author has paid to American practice in this respect a well merited tribute. The recognition by the author of American practice, which antedates anything of the kind abroad, imperfect though it may be in the light of present knowledge, only goes to show, if proof were needed, that the so-called practical engineer of the present day is no longer guided by "rule of thumb" alone, but is fully alive to the necessity of an accurate knowledge of the materials with which he works, guided by an intelligent comprehension of the principles which should regulate their use. The author of the book in question has taken occasion to call in question certain recent experiments made in this country, and Prof. Thurston has, by request, furnished an appendix to the American edition, treating of the strictures referred to in the text. In the appendix by the author will be found a review of the various methods thus far proposed for the dimensioning of parts, given at such length that these methods may also be used if desired, while their relative merits as well as the merits of the method advocated are well brought out.

Chinese Miners.

The old "lava beds," as they are called, in Butte county, are being thoroughly worked over by Chinese miners, who are able to take out from one to three dollars per day to the man, making a yield of from \$10,000 to \$15,000 per month from these mines during the entire summer and fall. The *Mercury* says that at present there are an unusually large number of men at work there on the old claims, and some of them on new ones just opened up, so that the business of mining is going on as brisk as during the years of 1874-5, when several thousand Chinamen were at work. The *Mercury* states that owing to the large influx of white labor into the county the Chinese had been turned off and were compelled to go to mining again or starve.

A curious feature in this connection is the fact that several new steam pumps have been put in operation by these miners to keep the mines free of water. John usually rigs up some kind of a contrivance of his own to accomplish his ends, and does not take kindly to machinery of any style where hand-work will do at all. In this instance, however, he can do little with his crude water-raising apparatus, and has to fall back on a full-fledged steam pump.

The Heald & Sisco Centrifugal Pump.

The engravings on this page represent different styles of the Heald & Sisco centrifugal pump, lately introduced on this coast by Parke & Lacy, 417 Market street. The principle of the centrifugal pump is so well known as to need no particular explanation. These steam pumps are used for a great variety of purposes, and especially in places where there is a great amount of water to be raised in a short time, and with slight expenditure of power.

Fig. 1 of the engravings shows the vertical Heald & Sisco pump, which is intended to stand on the bottom of the tub, well or reservoir, as the case may be, or it can be fastened at any required distance from the bottom; the only essential point being that the pump should be constantly immersed in the fluid to be raised.

FIG. 2. HORIZONTAL PUMP AND SELF PRIMER.

The scroll or shell, A, is of brass or cast iron, as circumstances require, made in halves, and bolted together in the usual manner. The piston is attached to the shaft, D, and works in the scroll, running lightly in nicely fitted bearings. The fluid enters the pump at the bottom and is discharged at F. This style of pump is especially useful for draining lock pits, coffer dams, tan vats, etc., in short for any situation in which large quantities of very foul water, containing mud, sand, gravel, bark, etc.,

pressure system is the best when a moderate quantity of water is to be raised a great height. But when a large quantity of water is to be raised a short distance the centrifugal plan is preferred, as it accomplishes its results with small power. We now speak of centrifugal pumps run with a belt; when the question is narrowed down to a direct connection of engine with pump, it is obvious a limit is quickly reached. An oscillating engine of short stroke is the ideal machine for running a centrifugal pump by direct connection. There is less steam and less wear in general, and the engines are compact and simple. But oscillators have hitherto labored under serious objections, and have not, therefore, held their own against machines which were not open to these objections. The company manufacturing these pumps took hold of the oscillating engine to remedy the defects, and have succeeded perfectly. This engine saves steam, is strong, light and compact, and very cheap in view of its capacity.

Fig. 3 exhibits the main features of the machine as now made; D is the steam induction pipe; E the suction pipe; A the valve chamber on the cylinder, the rolling valve within fit being worked by an eccentric from the engine shaft. The guides for relieving the strain on the piston-rod project from the head of the cylinder, and are partially concealed by the counterbalance wheels J, J; but the end piece, G, is seen between the wheels. F is the force pump, used for priming the main pump B, through the pipes

FIG. 3. HEALD & SISCO STEAM PUMP FOR IRRIGATING, ETC.

are to be raised expeditiously and cheaply. It is not liable to get out of order or clog.

Fig. 2 is the horizontal pump with "self-primer," a machine for the use of wreckers, contractors, and all who want an efficient and reliable pump, to be run by the belt from their own engine. This is the same as though the vertical pump (Fig. 1) were turned on its side,

FIG. 1. VERTICAL PUMP.

the shaft then being horizontal—the circumstance which gives the pump its distinguishing name. In point of execution there is no important difference; but the horizontal has the advantage of being more readily examined in case of accident.

Fig. 3 is the Heald & Sisco steam pump for irrigating, draining, wrecking, and for work in mines, quarries, etc. With all the numerous pumps in use it is well known that the direct

Trial of a Fire Extinguisher.

By invitation of Mr. G. W. Cummings, 126 Kearny St., agent for the Pacific coast, we were present on the 6th inst., at a trial of Rees's patent compound fire extinguisher, (Bucher's system improved).

The trial took place on Market street in front of the new City Hall, and among the spectators were Mayor Bryant, Chief Engineer Scannell and several insurance agents. A shanty of rough redwood boards had been smeared on the inside with tar and coal oil. A sort of table extended nearly across the shanty and on it was a row of iron pans containing tar, coal oil, benzine and naphtha.

These combustibles were connected with each other and with the wall by means of wicks of paper also saturated with oil.

The maker's description of the exterminator is as follows: "Rees's patent compound fire extinguisher (Bucher's system improved,) is a dry, solid mass, contained in cylindrical boxes of heavy pasteboard set in tin, of the weight of from 5 lbs. to 20 lbs., according to requirements. This mass is ignited, when needed, by the application of a lighted match or burning coal or cigar held to a fuse which protrudes from the box and causes the mass to burn gradually, without exploding, and to form the gases which are the exterminators of all other fires."

The combustibles were set on fire, and when the flames had extended to the walls a 12 lb. box of the extinguisher was ignited, pushed into the room, and the door closed. A tremendous amount of heat and smoke was developed, and, as there was a gale of wind from the west, it seemed for a time as though the fire would have the best of the contest.

Finally, however, the extinguisher conquered and, on opening the door, no flames were visible.

There was abundant evidence of the intense heat that had prevailed for a time in the charred walls and roof, and the tar which was boiling in the pan. The oils were consumed or evaporated.

The agent for the extinguisher claims that it is of particular value in closed buildings, where the gases given off are confined so that they have a fair chance to smother the fire. The building used in this case had a pipe through one corner of the roof, and, as we stated above, a high wind prevailed.

The makers give various cases where this article has prevented serious fires, in some cases having been put into operation by accident, as it were.

Simply storing a few packages of this extinguisher among valuable goods is claimed to be a very great protection.

The New Yellow Jacket Hoisting Works.

At Prescott, Scott & Co.'s Union Iron Works in this city, they are just shipping the hoisting works for the Yellow Jacket mine on the Comstock. This machinery is very heavy and substantial, and is intended for the new working shaft being sunk to the eastward of the old works, which is now down 727 feet. These hoisting works have two steam cylinders 18 inches in diameter by 24-inch stroke. The engine shaft is eight inches in diameter with a 25-inch pinion. The pitch of the pinion is three and one-half inches by 18-inch face. This hoist can be double-gear with a pinion 25 inches in diameter on the engine shaft working into a wheel 80 inches in diameter on a 10-inch intermediate shaft; and on the same shaft is a pinion 34 inches in diameter working into a spur wheel 165 inches in diameter. The change of gear is effected by sliding the intermediate shaft in and out by means of a screw and hand wheel on the outer end of the shaft. The object of this gear is for raising pumps and other heavy weights. This is a new arrangement altogether, as a separate engine is generally used for the purpose, and the means adopted in this instance answers for both. The reel shafts are 9 and 12 inches in diameter, respectively for the reels, of which there are two, 40 inches in diameter by 5-inch face. They can be worked together or separately with suitable clutches. Each of the spur wheels is furnished with a powerful brake, 15 feet in diameter by 6½-inch face, worked by suitable levers connected with a hand wheel gear.

There is also a brake on each of the engine cranks—another improvement insuring greater safety. These cranks are made 6 feet in diameter and very heavy, forming balance wheels for the engine. Each reel is furnished with the latest improved indicators, for telling the depth. The one used is the best one yet devised. On the dial plate is a spiral thread, in which the needle or pointer works, and instead of this pointer having to indicate the depth by one revolution, the use of the spiral gives it three revolutions, thus insuring greater accuracy. In a deep mine where a great deal of cable is out the old way is not accurate enough, but as the depths are plainly marked on the spiral thread, space enough is given for accurate indicating. The indicators are worked by suitable worm and screw wheels from the reel shafts. This machinery is all very heavy and finely finished. All the bearings are bushed with brass and fitted with tightened wedges. Each engine is furnished with link motion reversing gear, patent balance slide valves, etc. This machinery is among the heaviest on the Comstock, weighing altogether about 90 tons, and is capable of hoisting from any depth to which the shaft is likely to be sunk.

ORE.—We have received from H. C. Cory, Etna, Siskiyou county, California, some samples of quartz from his mine. A few hundred tons of rock like that sent would be handy to have in these hard times.

THE POPE'S "golden jubilee" was very generally celebrated on Sunday last with appropriate ceremonies, by Catholics.

Continued from page 366.

difference if it bore the construction which plaintiff endeavors to put upon it.

Under the law of the United States, as it had existed for more than six years at the date of Heynemann's contract to sell, the plaintiff was incapable of occupying, enjoying or securing the Government title to mining lands. Whether or not, as a matter of fact, the officers of plaintiff knew this is of no consequence. As matter of law, they must be held to have known it, and to have known also, that if they received a conveyance of the claims and took possession of them they would immediately become subject to re-location, by any citizen of the United States, who, under such re-location, could at once turn the plaintiff out of possession, and by compliance with the law, secure the title to himself; for, obviously the exclusive right of citizens to occupy is incompatible with any right of an alien to occupy, whether under a location made by himself or purchased from a qualified locator. This principle is settled by the decision of the United States Circuit Court for Oregon in the case of Chapman vs. Toy Long et al. (*Pacific Law Reporter*, August 15th, 1866.)

It was held that the defendants, although they were in peaceable possession of the claims when located by the complainants, were, because of their alienage, to be deemed trespassers upon the rights of the latter.

This fully sustains the proposition above stated: That if the plaintiff, upon the issuance of its stock to Heynemann, had demanded and received a conveyance of the claims mentioned in the contract, they would immediately have become subject to relocation by any citizen of the United States. To avoid such a contingency it was necessary that the title should be left in Heynemann, as the ostensible owner of the claim, and such was the course pursued. It was agreed that Heynemann should take possession of the claims and hold them as the agent and Trustee of plaintiff, and that, as the ostensible owner, he should apply for and obtain the Government title. It is strenuously contended that this is no proof of an intention on the part of the plaintiff to evade the policy of the law, but we are bound to say that we cannot regard it in any other light. The plaintiff may not have known the law, but it must be held to have known it; and its conduct was perfectly consistent with the supposition that it fully understood the extent of its incapacity to hold unpatented mining lands—that is to say, it acted precisely as any alien would act who deliberately designed to circumvent the law, and obtain by indirect and evasive means that which he was forbidden to take by direct means. If this contract should be upheld and enforced, so much of the law of the United States as excludes aliens from the right to occupy and enjoy the public mineral lands would be completely nullified, for it would only be necessary for aliens hereafter to follow the example of this plaintiff, in order to place themselves substantially upon an equal footing with citizens in the enjoyment of a privilege which the law has granted to citizens exclusively. If authority were needed to support so plain a deduction it exists in the amplest abundance. The State and Federal Reports are full of analogous cases arising under the pre-emption laws. We are constrained upon the principle established by these cases to hold that the contract upon which the plaintiff relies was void, and cannot be enforced.

This decision was delivered by Judge Beatty and concurred on by Judge Leonard. Judge Hawley, however, dissents. He says: In my judgment the contract declared upon and the trust sought to be enforced by appellant are not invalid on account of the alienage of said appellant, or void as opposed to public policy, as declared by the paramount law of the land. After quoting the law he says: Now, if an alien can lawfully purchase and hold valuable mineral deposits from any citizen who has obtained a patent from the Government, why cannot the citizen, prior to obtaining the patent, make a valid contract with an alien to convey the mine after the patent is obtained? If there is no statute directly prohibiting the making of such a contract, it can only be declared null and void for the reason that it is a fraudulent attempt upon the part of the contracting parties to evade the spirit of the law, and hence was, and is, in violation of the policy of the Government in relation to the mineral lands. The fact that express power was given to the citizen to alienate the title after obtaining a patent does not necessarily imply that before patent obtained he could not make a valid contract to convey the land after the issuance of the patent.

We are, however, told that to uphold this contract would enable aliens to evade the law and accomplish indirectly what could not be done directly, and that the result would be that the beneficial provisions of the mining laws in favor of citizens would be entirely set at naught. But in what respect is the contract in violation of the policy of the United States in relation to the mineral lands? It is true that statutes are not to be evaded any more than they are to be disobeyed. Yet it must be admitted that courts and judges, as well as other individuals, often differ very much as to the nature and extent of the policy of any law, and it is, to say the least, a very unsatisfactory reason, as well as unsafe rule, to declare a law void as being opposed to public policy.

It has been decided by the Commissioner of the General Land Office that a corporation created by the laws of the State, and performing

its functions under the authority of the State, may obtain a patent for a mine from the United States, although the stockholders may be aliens. Under this construction of the law, could not aliens make a valid contract to purchase a mine from any citizen who would agree to incorporate his mine under the laws of any State, and to have the stock of the corporation issued in the name of the alien purchasers? In such a case the aliens, by using the name of a citizen, could obtain a patent from the United States, and thus, in effect, if we adopt the argument of respondent's counsel, do indirectly what they could not do directly. Again, to pursue this line of counsel's argument, the aliens using the name of the citizen corporation need not obtain any patent, but, under the liberal policy of the Government, could hold the land and be protected in its enjoyment, and thus do indirectly what could not be done directly. The fraud in the case suggested would certainly be more apparent than in the case under consideration, for there the Government might actually be defrauded out of the purchase money.

It is a fact, of which we are, perhaps, authorized to take judicial notice, that aliens are stockholders in many valuable unpatented mines within this State, and that actions brought by them to protect their rights are frequently instituted and maintained in the Circuit Court of the United States. Now, if this action can be defeated because a citizen, for a valuable consideration, in good faith agreed to obtain a patent in his own name, and then convey the title to an alien, how much stronger the argument when applied to cases where the aliens have procured the stock of the citizen corporation that has failed to procure a patent from the Government! These suggestions tend to show how easy it is to imagine a case where a fraud might, perhaps, be perpetrated; or to imagine a case where the policy of a law might in some indirect way be partially evaded; but do not, as I think, tend to establish the fact that the contract in question was made for any such purpose, or that, if sustained, it would lead to any such results.

In the absence of any law declaring such contracts void, I think the question is, and should be, has the Government been defrauded, or its policy evaded?

Courts, in upholding contracts of this character, when made in good faith, would, in my judgment, protect both the citizens and the government. The citizen, after legally acquiring the right to obtain a patent, would be protected in his right to dispose of his interest upon the most favorable terms that capital might offer, and the Government would be protected by the purchase made by the citizen in pursuance with his contract with the alien. The alien, resting under the disability of the law which fails to protect him in the location, occupancy or purchase from the Government, is compelled to pay full value for the land and to have the law in all respects fully complied with by the citizen before he can obtain a title to the property.

I do not understand counsel for respondents to contend that the statutes of the United States in relation to the mineral lands changes the common law rule in any respect after the issuance of a patent; but they claim that under the statutes the alien is not permitted to make the purchase until after the patent is obtained, and that the contract herein sought to be enforced having been made before the issuance of the patent to Heynemann, it was absolutely null and void.

In the consideration of this case I have treated the contract between Heynemann and appellant as an agreement to convey the lands after the patent was obtained, for such, in my judgment, is the proper interpretation to be given to it. It is true that in the original agreement no such covenant appears to have been made, but the original contract was in many respects changed, by the consent of both parties. The agreement was first made before the plaintiff became a body corporate, and Heynemann then agreed to sell the mines for the sum of \$235,000. After plaintiff became a body corporate, Heynemann agreed to take 25,500 fully paid-up shares in the corporation, in lieu of the money, and while he remained in possession of the property, acting as the agent of the purchaser, he, in apparent good faith, suggests that it would be best, before executing the conveyance, to perfect the title in himself by procuring a patent from the Government. This was agreed to, not for the purpose, as respondents argue, to defraud the Government, but for the purpose, as above stated, of obtaining the title in Heynemann's name, so that he could make a valid deed of conveyance, as he had theretofore agreed to do.

From the reasoning of the authorities cited, and the particular facts and circumstances of this case, I am of the opinion that the alienage of the plaintiff in this action does not, of itself, incapacitate it from enforcing the contract as against the defendant, Heynemann, and that Heynemann, having obtained a patent from the United States, is not now in a position to take advantage of such alienage as a defense to prevent plaintiff from enforcing, as against him, a specific performance of the contract for the sale of said mineral land.

The plea of alienage has never been favored by the courts, and even admitting that the principles involved in this case are not free from doubt, I should, nevertheless, deem it to be my duty to give the benefit of that doubt in favor of the proposition which, while protecting the citizens and the Government, also furnishes some security to the alien, who, relying upon the good faith of the citizen and the Govern-

ment, without any direct violation of the law or any attempt to evade its spirit, or defraud the Government, or to interfere with its policy, is willing to lend his capital in the purchase of mines, and thereby aid and assist in developing the mineral resources of this State.

Entertaining the views herein expressed, I am compelled to dissent from the opinion and judgment of the Court.

Honorary Names in Scientific Nomenclature.

A few weeks ago an article appeared in the columns of the *Pacific Rural Press*, criticising the action of Mr. J. G. Lemmon, of Sierra valley, in naming a new flower—*Gilia Parryi*—"to honor a noble lady who has done eminent service for botany," etc. Mr. Lemmon answers the criticism by explaining the propriety of admitting a few such names to the records of science, in accordance with the practice of the masters in each, to the annoyance, it appears, of a few persons, who have evidently not given the subject much thought:

The plea for descriptive names is an old one, and many a scientist has kept strictly to the practice of giving them only, and by this very method has introduced confusion of the worst character into our nomenclature.

Let us look first to the origin of science and of scientific names. "Science is knowledge systematically arranged, so as to be conveniently taught, easily learned and readily applied."

Art is this knowledge applied to use. Coming down the steps of time, a master-mind arises one after another, seizes the materials at hand, arranges, names, publishes his book and departs, leaving his impress upon the science more or less indelible, according to the strength of his mind or the admiration of his followers. When all the known objects of a particular science or branch of science are thus collected and compared, no difficulty is found in distinguishing each from each, and very appropriate names are generally given them. As research continues, however, and more genera and species are added, many of the established names are found no longer distinctive, others are vastly more applicable to the new forms, etc.

Again, descriptive names sometimes prove indefinite afterward, because of the accumulation of material, showing that the first name was given to an aberrant form or variety, totally different from the typical plant or animal.

Still again, the early scientists, working with inferior or no instruments, made continual errors, both of observation and interpretation, hence their names are now mainly inappropriate or misleading. With every re-organization of a science, there comes an attempt to correct these manifold errors, followed in turn by confusion and contest, measured by the amount of re-naming done and the weight of the new authority. We can never hope to have our scientific names crystallized into a nomenclature as permanent as the conglomerate rock until research has revealed every form of plant that grows and every kind of animal that lives on the earth.

One of the first things we teach our pupils in science is the appropriateness and beauty of scientific names. We expatiate upon them with great pleasure and generally make the theme attractive, but no sooner does our tyro get well into the meshes of a science, than he finds one after another of its nice distinctions failing utterly, and that to follow the literal meanings would often totally mislead. Thus we learn to regard technical names, especially those coming down from the old masters, as distinctive only, not necessarily descriptive. Names denoting locality are often quite as unfortunate as descriptive ones. I could fill the *RURAL* with proofs that descriptive names as often fail in time to distinguish objects, as they continue to distinguish them. The name becomes merely a meaningless term, retained out of reverence for the author or to show the early conception of the object.

Linnaeus and Cuvier—worthies held in reverence by every true lover of nature—were the pioneers of modern research, and no better proof of their ability is needed than the statement that they studied and gave scientific names to every plant and animal known at their day, many of which names are retained to the present and, no doubt, a few will be until the end of time; but, as a matter of history, nine-tenths of their names have been quietly dropped or boldly overruled by subsequent scientists.

The thing aimed at in nomenclature is *distinctiveness*; the giving of such a name as will forever distinguish the object from every other in creation. In the naming of large families the distinctions become less prominent and certain, while upon the accession of a large number of species, the whole family has again and again to be revised. Each scientist aims as far as possible to give descriptive names, but each learns from his predecessors how meaningless most of them become; so he casts about him for other names that will stick he hopes, through time.

And right here comes in one of the most beautiful and touching characteristics of the true scientist—the recognition of the labors and merits of others. Full well he knows the toil and exposure of the explorer, the study and

pains-taking of the discoverer; and also how illy both are requited with this world's goods; so he is ever ready to give the poor meed of honor to whom honor is due. With an object before him, the result of severe exploration or research how natural that the discoverer's name should be indelibly associated with the new object; and with what love and loyalty he coins it into a technical distinction for the object given by unmeasured toil to science and the world.

Generic names are Latin nouns arbitrarily formed often from some medicinal or other virtue, real or supposed, or some resemblance to other objects, or they are derived from a country, or they are old classic words of no meaning whatever; and lastly they are sometimes coined from the name of a distinguished scientist or patron of science. Specific names are Latin adjectives, singular in number and agreeing in gender with the name of their genus. They are mostly founded upon distinctive characters, resemblances, uses, etc., and quite often are commemorative names. Specific honorary names are of two kinds: possessive and dedicative. If the person honored is the discoverer, his or her name is used in the form of the Latin genitive (or possessive case); as, *Viola Nuttallii*, *Cheilanthes Cooperi*. If the name is conferred as a recognition of merit, it is used as an adjective ending in *nus*, *na* or *num*; as *Ceanothus Veitchianus*, *Uncus Mariana*, and *Lilium Bloomerianum*, when the object is said to be dedicated.

The number of commemorative names of necessity will always be few compared with descriptive ones, but as every science has a small number it is quite certain that each will always retain a few in accordance with the law of human kindness, which, it is hoped, will always meet return.

What warm heart does not cheerfully acquiesce in the grateful affection of eminent scientists who have dedicated certain small genera of plants or animals to Linnaeus, Cuvier, Jussieu, De Candolle, Levoisier, Maximowicz, Agassiz, Adanson, Audubon, Berlandier, Bentham, Brown, Bigelow, Baykin, Brewer, Canby, Cary, Chapman, Clayton, Chamisso, Clinton, Dahl, Davy, Dana, Descartes, Engelmann, Eaton, Eschscholtz, Douglas, Faraday, Franklin, Fuller, Gay-Lussac, Gray, Hooker, Hudson, James, Jefferson, Kuhn, Lamark, Lavater, Le Conte, Lindley, Ludwig, Marsh, Marshall, Menzies, Michaux, Mitchell, Nuttall, Olney, Packard, Pursh, Richardson, Riley, Sprengel, Sullivan, Silliman, Thurber, Torrey, Towne, Tyndall, Wood, Watson, Wilson, Willdenow, Whitney, Wright, Parry, Palmer; and our Californians, Bolander, Kellogg, Bloomer, Davidson, Harford, Harkness, and Edwards.

Please permit a few words in regard to my practice of suggesting names and how I commenced it. In September, of 1873, I was suddenly informed that a plant had been named for me by Dr. Asa Gray, of Harvard University, at the instance of Prof. Bolander, who had recently been botanizing Sierra valley with me. I was thus ushered into the large and interesting family of *Astragalus*. I found myself in good company. There was Pursh, Gray, Hooker, Geyer, Coulter, Menzies, Douglas, Horn, Anderson, Morton, Parry, Whitney and Bolander.

But other good people to my knowledge were outside; I at once determined to try to get them within. I traveled extensively, collected largely and noted carefully. With every package of plants sent to Dr. Gray went up petitions of this import: "Should such and such a plant prove new, and it does not name itself by obvious characters (which is always best), please dedicate it to so and so, for the following reasons," etc.

My petitions have often been granted, and with great joy I have celebrated the admission, one after another, into the family of *Astragalus* alone, Mrs. Pulsifer-Ames, Dr. D. G. Webber, Prof. E. L. Case and Mrs. R. M. Austin; and, did your readers know these parties, I don't think one would protest.

MOUSTACHE PROTECTOR.

Will fit any Cup. Gent's Delight. Boss Novelty for Agents. Big to sell. Gent's must have it. Ladies buy it for them. Only 25c by mail. Circulars free as air. Storekeepers, let me whisper to you. C. H. BARROWS, Patent tee, Willimantic, Conn.

WANTED.

QUICKSILVER FLASKS.

Second-hand will be bought for cash on delivery, if in good order and full size. State quantity and price.

P. O. Box 1078, S. F.

FOR SALE OR LEASE.

Corey & Kingery Mine for Sale or Lease. This mine is a gold bearing quartz lead, situated on French Creek Siskiyou county, Cal., 7 miles south of Ena. Mine opened by tunnel and shaft 370 feet below surface; average width of lode, 18 inches. For further particulars call and examine our mine, or address us at Ena, Siskiyou county, California. H. C. COREY, D. B. KINGERY.

Don't trifle with a poor watch when you can buy a good one of Dewey & Jordan, 433 Montgomery street, San Francisco, at prices according to the times.

Steam Engines & Boilers.

NEW AND SECOND-HAND.

One Patent Straw-Burning, Portable Engine, (new,) fire box boiler, the best Portable Engine on the coast; built by Ransom, Sims & Head, Ipswich, England.

One Steam Fire Engine, second-hand, in excellent condition, with 200 feet leather hose, very cheap, just the thing for a small town. Button & Blake, builders, Waterford, N. Y.

One second-hand Stationary Engine, 14x30 inches, link motion, with or without hoist gear.

One second-hand Stationary Engine, 8x20 inch, with or without hoist gear.

One Upright Boiler, Horizontal Engine on wheels, Eastern make, 7x12.

One Upright Boiler, Horizontal Engine, San Francisco make, 6x12.

One small Stationary Engine, 3½x7 inch.

One Steam Boiler, 40 inches diameter, 16 feet long.

One 8x10 Straw-Burning Portable Engine.

One Traction Engine, three wheels, rubber tires, double cylinder, 6x10 inch; Thompson's patent, D. D. Williamson, builder, New Jersey.

Various other second-hand Engines and Boilers for sale cheap.

Superior Pianos for the People at Popular Cash Prices.

More than TEN THOUSAND prosperous families on this Coast need Ten Thousand GOLDEN PIANOS to make TEN THOUSAND HOMES MORE PLEASANT AND ATTRACTIVE.

Prices of good Pianos have long been too high. Our people could not afford to buy them. But many will find it not only pleasant but profitable to purchase

The Brilliant and Durable GOLDEN PIANO

Which we now offer the readers of this paper

At Greatly Reduced Popular Cash Prices.

We Guarantee them to be as represented, of superior tone, finish and durability.

Samples can be seen by calling at this office. We keep no expensive sales-rooms and attendants.

We shall sell none but superior and desirable instruments, but give our customers the benefit of prices far below any before offered on this side of the Continent.

Prices of the Golden Piano:

	The Installment Plan Prices.	Our Reduced Cash Price.
The Golden Piano, \$500	\$350	
(UPRIGHT-C.)		
The Golden Piano, \$375	\$300	
(SQUARE-No. 1.)		
The Golden Piano, \$500	\$350	
(SQUARE-No. 2.)		
The Golden Piano, \$600	\$400	
(SQUARE-No. 3.)		
The Golden Piano, \$800	\$450	
(SQUARE-No. 4.)		

We invite our readers who wish to look at Pianos for themselves or friends, for immediate or future purchase, to call and examine our samples.

Those who cannot call will be supplied with further descriptions and recommendations by sending to this office.

Buy the Best.

Before purchasing an American Watch, examine the different styles manufactured by the NEW YORK WATCH COMPANY, at Springfield, Mass. They are the latest and best improved manufacture. You can depend upon them for fine finish, durability and perfect time. They are sold at favorable prices—in fact, no higher than many of the inferior styles. Examine into the merits of this Watch before you buy any other. Our word for it, you will not regret it.

DEWEY & JORDAN, Agents,

Office, No. 320 Sansome street, Room 10.

Continued from page 365.

ning in good vein matter, with streaks and bunches of ore occasionally encountered.

SILVER HILL.—The upraise above the 444-ft level is progressing upward in lower grades.

HALE & NONCHOS.—Reducing the water slowly, but getting the best of it. It is reduced sufficiently to see that the timbering of the incline holds good, and a point nearly 100 feet below the 1900-ft level has been reached.

BULLION.—At the 2000-ft level streaks of good looking quartz are making their appearance in the face of the drift.

SERRA NEVADA.—At the 1500-ft level the cross-outs both east and west from the main south drift continue in quartz and low grade ore.

DAYTON.—The work at this mine consists in the development of the ore bodies at the 400 and 220-ft levels.

MORNING STAR.—The old upper tunnel is showing some very good ore.

ATLANTIC CON.—The bottom of the winze below the main adit tunnel continues in quartz and low grade ore.

Arizona.

LUKE'S MILL.—*Arizona Miner*, May 25: This mill is about on the ground, and a portion of it is already up. It will take about four weeks before the machinery will all be in place and the mill in working order.

HACKBERRY.—Mr. H. C. Stevens, from Hackberry, arrived to day, and informs us that the company have been running their old mill on tailings, and after nine days' run cleaned up \$7,300 in bullion. The shaft of the Hackberry mine is down 450 feet and the lead shows at that depth excellent ore. The company's new 10-stamp mill had arrived at Hardyville.

GLOBE DISTRICT.—Globe City, the principal place in Globe mining district, has a shifting population of about 300. Everything is terribly dull here, owing to the lack of capital to develop the mines. There are two stamp mills here, one two stamp and the other five stamp; but their returns have been so unsatisfactory that the miners have no confidence in them and will not furnish them with rock. Mr. Kennedy has a smelter here, but as lead is too high, it makes that way of working so expensive. The ore of this district contains in large quantities iron, copper "glance," antimony and sulphur, and most assuredly requires roasting.

There is very little free milling ore found here. Messrs. Townsend, Jerrold and others, of Caribbo, B. C., have settled here, and sent on to San Francisco for a complete ten-stamp mill, with a "mechanical roaster." Messrs. J. D. Wilson & Co. are also having a mill built, with a capacity of twenty tons per diem, to erect in this district. As soon as these mills are erected and in working order, the miners will commence working their claims; and, as they can take their own ore and have it successfully worked, they can thus make expenses while developing their mines.

Idaho.

PROSPECTING.—Owyhee *Avananche*, June 2: We are glad to learn of the success of so many persons engaged the present season in prospecting the neighboring hills and mountains. This is infinitely better than lounging about hotels and loafing in bar-rooms. There is abundance of good ledges scattered all through these hills, and it only requires a little energy and hard work to get at them.

BULLION.—Quite a large quantity of bullion has passed through here recently for the railroad, shipped from different sections of the Territory. Two messengers left here on the stage which went below on Saturday evening.

GOLDEN CHARIOT.—The flow of water which usually interferes with mining operations here in the spring has somewhat retarded operations at the Golden Chariot during the past few weeks. No difficulty, however, is experienced in handling it, the heavy machinery at the mine being quite adequate for all such emergencies. A good yield is expected from the present crushings, the pulp assays ranging from \$40 to \$200 to the ton. The Superintendent expects to make the first bullion shipment of the Chariot in a day or two.

EMPIRE.—The progress of operations at the Empire continues to be most favorable. Work is going on in the sixth level both in a north and south direction, and the result leaves no doubt of the promising character of the ore shaft.

There are quite a number of persons working on small claims, scattered throughout the hills, and several good prospects are reported.

Montana.

CLARK'S FORK.—*Bozeman Afloat Courier*, May 28: The proposition looking toward lease of the smelter works, was not favorably considered by the company. It has such faith in the richness of the various leads, that it determines to proceed immediately to completion of the work begun last season. Preparations are now being made for the departure of a party of workmen in charge of some of the stockholders; and on the 1st of June a number of land owners will start for the mines outfit for a season's extensive work. We have reason to think more practical development will result this summer than ever before, and should no disappointment follow, a busy camp will be found next year at Clark's Fork.

Oregon.

QUARTZ.—*Oregon Mining-Immigration Journal*, May 25: Great excitement exists at Langell's valley. Lake county, over a very rich quartz ledge recently discovered by Wm. Bloyd. The County Clerk is one of the principal owners.

R. J. CAMERON is engaged in constructing a ditch to bring water to the mining-grounds on the Little Apple Creek, Jackson county.

FOR THE MINES on Little Apple Creek, 1500 feet of 15 inch pipe has been received. The nozzle weighs 400 pounds. There is 200 feet fall, and the amount of dirt it will wash out in a day is enormous. The pipe cost \$2,500. The whole length of the new ditch on Apple Creek is 19 miles. It will carry 400 inches of water.

PREPARATIONS are being made for sinking a shaft for an air shaft and means of hoisting ore in the Capital. The veins now show solid quartz about two feet in length, and the owners of this mine, with proper management, have a good thing. Some very rich specimens have lately been shown from the Capital.

ON COYOTE CREEK, Douglas county, Kelley's claims have paid \$10 per day to the land for all the work done in the mines since last fall. The claims above Kelley's which were worked during the mining season just passed, have all paid more than wages, with one exception.

MINERS in the gravel beds below Galesville are doing well.

There is plenty of water in the mining flume at El Dorado, Baker county.

About two weeks ago a man by the name of Short sunk a shaft (on a point of a hill near Pocatones, in the vicinity of Mill Creek, about five miles west of Baker City), about 25 feet in depth, and found an old lake deposit of rotten boulders and gravel, rich in gold, paying from 5 to 50 cents to the pan, some say more. Short did not reach the bedrock, and is now drifting. Some 30 or 40 claims have been located, and the presumption is that our palmy placer mining days will come again. There is plenty of ground left to be taken.

The Camp Creek mines are about 175 miles distant from the Dalles. Stages leave Dalles for Prineville every Monday morning; returning, leaves Prineville every Thursday; distance from Prineville to Camp Creek, 50 miles. The mail service will soon be extended to Camp Creek, and the coaches be put on between the Dalles and the mines.

Utah.

BINGHAM.—*Cor. Salt Lake Tribune*, May 27: Utah's mining interests are no longer based upon wild-cat speculations. Excitements are merely local. When mines are purchased, the inducements are such as to leave no

doubts in the purchaser's mind, and remunerative investments are to be made.

This Glasgow company (German, Greeley & Vulcan) works a full force. This company is about to erect a ten-stamp mill close to their mines, to work up their own ore. Mr. Jackson has a large force grading out for the mill, and is looking for the machinery soon.

DISCOLL, CULLEN & Co. have struck a large body of high-grade ore in the Caledonia. We congratulate the boys on their strike, as they have expended a good deal of time, money and labor upon this property. It is now one of our bonanzas.

ELMS & Co. are doing well on the Tiewatke. Wimmer and Dixon mines are doing as usual, shipping. At Sandy the Flagstaff smelter consumes 130 tons of ore every 24 hours. He employs 100 men and works eight-hour shifts.

The following mines are being worked: Neptune and Kempton, Live Pine, Ashland, Albion, Fanny Bonny, Ten-Forty, Chattanooga, British Flag, Cotton Tunnel, Saturn, Last Chance, Elmore, Jordan, Mary Ann, Utah, Spanish, Wall Street, Castro, Victor Tunnel, Old Telegraph, Reverse, Yosemite, Telegraph, Miner's Dream, Black Metallic, Evergreen, Morning Star, Omaha, Shakespeare, etc.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

PUGET SOUND PLANING MILL CO.—June 4th. Object: Manufacturing, rounding and finishing masts and spars and all work that can be manufactured by the cylinder planing process. Capital stock, \$50,000. Trustees: Wm. Irvine, H. H. Hayden, J. C. McCurdy, Theo. L. Payne, H. G. Donnel, H. S. Tibbey, J. J. Lyon, P. Zadis and L. J. Lewis.

ARGENTA M. CO.—June 4th. Location: Nevada. Capital stock, \$5,000. Directors—W. H. Raymond, Alfred Welsh, T. E. Jewell and Henry Raymond.

COMBINATION M. CO.—June 5th. Location: Black Mt. district, Esmeralda county, Nevada. Capital stock, \$10,000. Directors—Thos. B. Hayes, J. B. Low, Charles Stevens, H. A. Charles and Wm. H. Clarke.

Civil Service Reform in the U. S. Patent Office.

Secretary Schurz has determined to test the competitive examination system very thoroughly in connection with the U. S. Patent Office. Recently, when a vacancy occurred on the Board of Examiners-in-Chief, he appointed a committee to examine applicants therefor, a thing until then unheard of with respect to a Presidential appointment requiring senatorial confirmation. It created considerable stir among the gentlemen of the office who aspired to the place, and at one time it was doubted whether the programme would be carried out, owing to opposition "to the innovation" on the part of some interested. But on the appointed day a baker's dozen appeared, including all who had been prominently mentioned for the place, and a gentleman not in the office, but who had resigned the place of Principal Examiner to go into the army, Dr. Antisell. The questions were confined to the law and practice in patent matters, and the occasion was entirely satisfactory to all concerned, and especially so to three of the number, who betrayed the most learning or were most successful in telling what they knew, and whose names were sent by the Commissioner of Patents to the Secretary of the Interior with recommendation that one of them be chosen to fill the place. Mr. H. H. Bates, who stood first, was chosen and appointed to the place, Mr. T. F. Wilber, who stood next, was made Examiner of Interferences, the place which ranks next in importance to the Board to which Mr. Bates had been promoted. The third was Mr. B. R. Catlin, who will stand a good chance of promotion on the next vacancy. The salary of Examiner-in-Chief is \$3,000, that of Principal Examiner \$2,500. There are three of the former and twenty-two of the latter, as the office is now organized.

Messrs. Bates and Catlin were then, together with Mr. B. C. Tiffany, of the Secretary's office, appointed a committee to examine applicants in the next lower grade for the vacancy caused by Mr. Bates's promotion, and also for two other vacancies that had been made, one by the resignation of a Principal Examiner, another by resignation. This examination, like the first, was eminently practical and well-suited to determine the relative qualifications of the competitors, of whom there were twelve, and the result has given universal satisfaction. Mr. H. C. Townsend and Mr. C. B. Church were the fortunate competitors; the former has been put in charge of electricity and cognate subjects, and the latter the class of metal-working machines and processes. Both have acquitted themselves with great credit as Assistant Examiners, are well known, and go into their new positions enjoying the confidence of practitioners and inventors alike. Mr. Church has gained an enviable reputation as Law Clerk to the Commissioner and has had large experience in the class over which he now presides.

To discharge acceptably their duties, examiners of patents (of whom there are in all, including assistants, 88 in the office) should have a competent knowledge of law and mechanics, and should be men of honesty, general intelligence and good judgment. Many important questions come before them. They are frequently called upon to decide questions involving large moneyed interests. It devolves on them to examine into and determine the novelty and patentability of an immense number of applications for patents on every conceivable kind of devices. The patent interests of the country have grown to enormous proportions since the war, and it is difficult to keep in the service, at the meager salaries paid by the Government, the men who distinguished themselves in the discharge of their official duties. It will be seen then that the competitive examination system can be made, as indeed it already has, to a considerable extent, of great avail in assisting

the appointing powers in filling vacancies as they occur among the examiners and their assistants. It should be said, however, that it does not follow necessarily under the civil service reform in vogue, that the man who stands at the head of the list will be promoted. The efficiency of the several candidates is taken into consideration in all cases, and due weight given thereto, but the Commissioner does not, in his recommendations to the Secretary, set aside the highest candidate as ascertained by the examination, and substitute one ranking below, without good and sufficient reasons, not likely to exist.

The whole number of patents granted up to May 15th is 190,947, of which 31,533 only had been granted March 4th, 1861, when President Lincoln was inaugurated. The number of applications filed during the centennial year was 21,425, and the number of patents granted during that year was 15,595.

The Secor Amalgamating Process.

We have several times made the statement that there are an enormous number of mines on this coast which are to-day lying idle, although known to contain large bodies of paying ore. The usual method of wet crushing in a mill and amalgamating in a battery and on plates is the old plan, and scarcely any improvement has been made upon it in the last 18 years. Concentrator blankets, sluices, etc., are slight adjuncts, but in the case of saving sulphurets, the cost of chlorinating still leaves but little incentive to work in that manner.

To show how unsatisfactory amalgamating in battery and on plates is, we will suppose that a ton of ore (crushed dry and fine, that no flour gold may float away), should be put in a pan with a large charge of quicksilver, and worked cold and without chemicals for four hours (because in battery and plates it is cold and no chemicals are used), the result would be from 60% to 85% of the fire assay. Now, if with such a mixing and working together of ore pulp and quicksilver the result is so far from getting good returns, how much could be expected in the battery when the larger part of the ore goes through the screen, without going within three or four inches of the quicksilver which lies at the bottom of the mortar; and on the plates when the flour gold passes over in a thick, muddy water, quicksilver having no attraction whatever for gold or silver, but merely taking them up when the proper circumstances exist.

It is not an unusual thing to hear mill men say "they save \$8 per ton and their ore goes \$30, and the tailings will only assay \$3 to \$5"—showing the great loss which goes off on the water, but attributed to the loss in the sulphurets, and not to the true fact of having floated away.

It is stated that by taking a phial containing, say a half ounce of flour gold, put in three or four ounces of quicksilver with water, shake well together, and only a portion of the gold will be taken up; heat the contents to 200°, then shake again, and a portion more will be absorbed, some of the flour gold still floating on the quicksilver; heat again to 300° the entire gold will disappear by shaking. We now come to speak of a device intended as a remedy against loss of flour gold and also of silver.

The Secor amalgamator or pan is a strong iron closed cylinder, with gearing on top and a shaft passing down through, with mullers set at an angle of 45 degrees, something like the blade of a propeller; the action of the mullers sends up the mixture of ore and quicksilver in the machine to the top. Their action is precisely that of the propeller of a ship, and their force may be easily estimated by reflecting for one moment on that exerted by a propeller. Their effect is to thoroughly mix the whole mass together. The ore to be treated is crushed fine, charged into the machine in quantities of one ton of 2,000 pounds; quicksilver is put in the charge, the manhole plate is then put on, everything made tight, and the ore submitted to the disintegrating power of steam under pressure of from 10 to 60 pounds to the square inch, giving from 240 to 307 degrees of heat. But little steam is used for a charge, the ore so far filling the machine as to leave a space of about one and one-half cubic feet; then a slight condensing until the mass is heated to above boiling point, which is very soon done, as the machine is hot when the charge is put in, steam being then produced from the mass by the heat within itself. It is calculated where steam is used for running the mill, that taking it from the boiler, the cost would not exceed five to 10 cents per day.

For saving very fine gold in ores—gold that floats and cannot be precipitated—it can easily be understood that in amalgamation the heat of the steam agitates the quicksilver; the mullers carry it up to the top of the charge, bringing it in perfect contact with the metal it is seeking for. When finished, all is discharged into a settler, when a new charge can be put into the machine.

In working the ordinary open pan a long time is required, and from five to six-horse power to drive it; and it is the custom to heat the pulp by means of false bottom, coil, jacket, or by letting steam directly into the pan, which only produces about 180 degrees of heat, for a much higher heat dries the pulp, requiring the addition of water.

It is claimed that the Secor pan can be run with one-horse power, and a charge is worked in an hour, or about 20 tons per day, equal to the work of four open pans, and saving about

20 to 25-horse power in accomplishing the same amount of work, the open pan saving 60 to 75 per cent., while the closed pan, in free milling ore, saves from 92 to 98 per cent. of the fire assay.

Mr. Secor does not claim to work all kinds of ore, but should it contain sulphurets in considerable quantities, or other base metals, they should be treated by roasting or otherwise, when the same percentage is obtained as from free ores. In a subsequent issue we shall give an engraving of this apparatus, so that our readers may have a better idea of its construction and operation.

Academy of Sciences.

The regular meeting of the California Academy of Sciences was held on Monday night. Prof. Davidson in the chair. Dr. Kellogg read a paper on a number of new plants, under the following names: *Spheralcea insularis*, *Ecnothera frutescens*, *Triclis insularis*, *Heterocodon hispidissimus*, *Astragalus insularis*, *Rhaecia plumosa*, found on the coast islands of California by the late Dr. Veatch, who was the first naturalist to make a collection on those islands; *Cnicus Marinus*, a species of thistle, found at Lone mountain by the same naturalist. *Gonolobus barbatus*, variety *subauriculatus*, collected by Capt. W. J. Fisher on the Gulf of California; *Mimulus Clarkii*, by Joseph H. Clark, of Mendocino county; *Berberis Nevadensis*, by Dr. Harkness, found in Fresno county.

A plant, common in San Francisco, *Soliva pedunculata*, was described as a new plant. Specimens had been sent East, but the Eastern botanists had not seen fit to admit the new species. It differs from the *Soliva* described in their books.

Three new plants, found by Henry Edwards, Esq., were described; *Streptanthus Edwardsii*, found at Knight's Landing; *Collinsia ochroleuca*; or White Collinsia, found at Skaggs springs, Sonoma county; and a remarkable specimen of the golden thistle, *Cnicus Vailii* (not of Gray) *Citrinus*, a plant of a bright yellow flower.

A collection of plants was received from Mrs. Dr. Tilling, of Oakland; and another (*Alga*) from Dr. Anderson of Santa Cruz.

A number of ores for the cabinet were received from Homiguera mine, Triunfo, Lower California.

A photograph of a prehistoric sepulchral vase was received from the collection of Dr. L. M. Dimmick, of Santa Barbara. It was excavated from the ancient burial mound at Ottawa, Illinois, found at the side of the head of a human skeleton. It is unglazed earthen ware, and forms one vessel, the four compartments being connected at the base. It strongly resembles in its quadruple form some specimens of pottery found in the burial mounds of the ancient inhabitants of Peru, South America.

A paper on "Foods" was read by J. P. Moore, on the utility of turning attention to this subject, and prepare a collection of all foods for the uses of the practical producer. He thought that producers would co-operate with the Academy, if the latter would take hold of the subject in earnest, and bring the facts of science home to the interests of the people.

Prof. Davidson read a paper on English break-waters. At the next meeting, he will read another on other similar works.

He stated that he had advice of the departure of Dr. Hooker, President of the Royal Society, and Prof. Asa Gray, to visit California this month; and that Prof. Morse, on his return from Japan, would deliver four or five lectures on geology, under the auspices of the Academy.

Chloride of Calcium for Street Sprinkling.

Hearing that there had been successful experiments made abroad in the use of a solution of chloride of calcium for street sprinkling, and of its great advantages for such use, we interviewed Mr. E. L. Ransome, No. 10 Bush street, San Francisco, who is a large dealer in the substance, to gain what information he had on the subject. He informed us that according to a statement recently made before the Academy of Sciences, of Paris, by M. Housenau, great advantage arises from the use of chloride of calcium instead of water in laying the dust of public thoroughfares. The salt is, as we all know, highly deliquescent, and is applied in solution, one application sufficing for a period of from five to seven days. Thus a roadway of one kilometre in length by five meters in width, which would require in hot, dry weather four waterings per diem with water, at a cost of 60 francs per week, supposing the water to be supplied free, would require only one application of the chloride, at a cost of 40 francs only, that is to say a difference of 20 francs in favor of the chloride. Trials have also been made in Rome of a solution of chloride of calcium as a substitute for water in laying dust in streets, and the results are said to have been highly satisfactory. The dampness communicated to the road remains for a whole week. The road remains damp without being muddy, presenting a hard surface, on which neither the wind nor the passing of pedestrians or horses has any effect.

This subject seems to us worthy of experiment, both in San Francisco and the towns of the interior. Besides laying the dust it might prove serviceable as a disinfectant in some putrid streets where diseases generate, thrive and run riot during the sultry months.

General News Items.

THE Queen of Holland died on the 3d inst. They are having trouble with the Indians again in Arizona.

A VERY destructive fire occurred at Vacaville on Monday evening last, destroying half the town.

The debt statement shows a reduction of the debt for May of \$6,981,274. The reduction from July 1st, 1876, to date is \$36,062,000.62.

THIRTEEN failures were reported in the last fortnightly statement of the London Stock Exchange, some heavy.

A TERRIBLE storm struck the town of Mt. Carmel, Illinois, on the 4th inst., destroying \$500,000 worth of property and 12 or 15 lives.

EX-PRESIDENT GRANT is being honored on every hand in Europe, as a representative American, showing the good feeling which exists between the two nations.

A TEST case has been decided in a United States Court, which decides that an Indian, residing on a reservation and in charge of an agent, is an alien and therefore he has no right to vote.

THE French frigate *La Magicienne* has arrived here from Callao, making the trip in 31 days. She has on board Admiral M. Serre, 34 officers, 465 men and 28 guns. She is of 3,000 tons register.

THE daily requisition upon the Third Assistant Postmaster General, for postage stamps and stamped envelopes lately, shows a steady increase, indicative of a marked revival of business throughout the country. On the 8th inst., exclusive of postal cards, the requisitions filled by the department aggregated 6,217,000 stamps and stamped envelopes of various denominations, with a face value of \$147,759.

JUDGE BARRETT of New York has rendered a decision in which he holds that the By-laws of the Longshore Union Protective Association, making it compulsory on members not to work for less than 40 cents per hour, is void, as being against public safety, and members of the Association dismissed for its violation must be reinstated. This decision affects 800 members of the Union, expelled for disobedience to said law, as well as to Trades Unions generally.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Ponds and Skating Rink.

DEWEY & CO'S
SCIENTIFIC PRESS
Patent Agency.

Office—224 Sansome St., San Francisco.

PATENTS obtained promptly; Caveats filed expeditiously; Patent reissues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments reported in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences presented; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Soliciting Business promptly and thoroughly conducted. Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons, and our success and business are constantly increasing. The shrewdest and most experienced inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

DEWEY & CO., Patent Solicitors.

San Francisco, 1877.

Mining and Scientific Press

Is the leading mining journal in America, and enjoys a large circulation among the more intelligent operators and workers in the gold fields of the world.

As a scientific and mechanical representative of the Pacific Coast, it is decidedly popular and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special sphere unrivaled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer will find profit by its reading.

Subscription, \$4 a year in advance. Sample copies, post paid, 10 cents.

DEWEY & CO., Publishers, S. F.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

And in accordance with law and an order of the Board

of Trustees, made on the thirtieth day of April, 1877, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at the salesroom of J. Middleton & Son, No. 310 Montgomery Street, San Francisco, Cal., on the twenty-fifth day of June, 1877, at the hour of two o'clock, p. m., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

GEO. R. SPINNEY, Sec'y.

Office, No. 320 California Street, Room No. 5, San Francisco, Cal.

Consolidated Bonanza Gold and Silver Min-

ing Co.—Location of principal place of business, San Francisco, California. Location of works in Engle and Washoe Valley Mining District, Ormsby county, Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees, held on the fourth day of June, 1877, an assessment, No. 1, of 10 cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary at the office of the company, No. 19 First Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on Tuesday, the tenth day of July, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the twenty-fifth day of July, 1877, to pay the delinquent assessment together with costs of advertising and expenses of sale. By order of the Board of Trustees, WM. MARTIN, Secretary.

Office No. 19 First Street, San Francisco, Cal.

Dolores Consolidated Mining Company.—

Location of principal place of business, San Francisco, California. Location of works, Dolores Mining District, Esmeralda County, Nevada.

Notice.—There are delinquent upon the following described stock, on account of assessment (No. 1) levied on the seventeenth day of February, 1877, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Amount.
Blasdel, H. G. trustee.	16	10,000	\$1,000 00

Builders of QUARTZ, SAW AND FLOUR MILLS,

Keating's Sack Printing Presses,

THE ECONOMY HYDRAULIC HOIST FOR STORES,
And General Machinists.

STEAM ENGINES AND BOILERS

Of all sizes—from 2 to 60-Horse power. Also, Quartz
Mills, Mining Pumps, Hoisting Machinery, Shafting, Iron
Tanks, etc. For sale at the lowest prices by

J. HENDY, 49 and 51 Fremont Street, S. F.

Miners' Foundry and Machine Works,

CO-OPERATIVE,

First Street, bet. Howard and Folsom, San Francisco

Machinery and Castings of all kinds.

McAFEE, SPIERS & CO.,

BOILER MAKERS AND
GENERAL MACHINISTS,

Howard between Fremont and Beale Sts., San Francisco

San Francisco Pioneer Screen Works,

J. W. QUICK, MANUFACTURER,

Several first premiums received
for Quartz Mill Screens, and Per-
forated Sheet Metals of every
description. I would call special
attention to my SLOT CUT and
SLOT PUNCHED SCREENS,
which are attracting much at-
tention and giving universal
satisfaction. This is the only
establishment on the coast de-
voted exclusively to the manu-
facture of Screens. Mill owners us-
ually can contract for large suppli-
es at favorable rates.
Orders solicited and promptly filled.
32 Fremont Street, San Francisco.

Machinery.

The Ingersoll Rock Drill

Is Extensively Used in the East and

TAKES THE PLACE OF ALL OTHERS,

Wherever introduced, because it can be run with less
power, labor and repairs, and do more work than any
other Drill in the market. It has but few parts, is easily
handled, being light, and has AUTOMATIC FEED, which
saves labor. WE ASK FOR TRIAL AGAINST ANY
COMPETITOR. For particular information regarding
Drills or Air Compressors, send for circular to

J. B. REYNOLDS,
320 Sansome Street
(Room 10.)

THE O'HARRA CHLORIDIZING FURNACE

Guaranteed to Chloridize from 85 to 95 per cent. of any
gold or silver ores that are not more profitable for smelt-
ing. Will also desulphurize ores and put them in proper
shape for working in cupola furnaces.

Cost of Roasting and Chloridizing 20 Tons
in 24 Hours by this Process:

One man.....	\$ 4 00
One man.....	3 00
Wood—23 Cords at \$3 per cord.....	5 25
Salt—1,600 lbs at 2½ cents.....	40 00
Cost of 20 tons.....	\$52 25
Cost of one ton.....	2 61½

In a furnace of three or four times this capacity the
cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Con-
solidated Co.'s mines, in Peavine District, Nev., and at
the Exchequer mill, Alpine Co., Cal. For further infor-
mation, apply to

D. J. O'HARRA,
Reno, Nevada.

SNOOK'S PATENT TANK FILTER.

It is self-regulating, will last many years without renew-
ing filtering material. Is simple, durable, easily cleaned, and
not liable to get out of order. A sure preventive against
snakes, worms, bugs and all other impurities in the water.
It will filter all the water required for any dwelling house,
and is not expensive. These filters are expressly designed to
use in place of a tank. May be connected to any
tank and through the usual pipes supply all the house, or the
water may be used direct from the filter, where no tank is re-
quired for other purposes. Every house should be provided
with one and thus avoid one of the most fruitful sources of
disease. Full satisfaction guaranteed and filters kept
repair free of expense. For sale by

G. & W. SNOOK, 427 Pine Street, S. F.

LEVI STRAUSS & CO.,

Patent Riveted
Clothing,

14 & 16 Battery St.,
San Francisco.

These goods are specially
adapted for the use of
FARMERS, MECHANICS,
MINERS, and WORKING
MEN in general. They
are manufactured of the
Best Material, and in a
Superior Manner. A trial
will convince everybody of
this fact.

Patented May 12, 1873.
USE NO OTHER, AND INQUIRE FOR THESE
GOODS ONLY.

Really Important.

Dr. Noon's combined Electro-Magnetic Sudatorium
Baths cleanse the system from Lead, Arsenical, Mercurial
and other poisons. Will cure Rheumatism, Torpid,
Liver and Chronic Disorders. Our system is the most ef-
fectual in the world, combining with all needed medi-
cines, Hygiene-Oxygen Inhalations, Electric and Hydro-
pathic treatment, all skillfully used as necessary. Often
cures where others fail, and always in less time.

Dr. Noon has had much special, practical experience in
the treatment of the disorders incidental to mining life.
Consultations free.

PICKERING ENGINE GOVERNOR.

VALLEJO FOUNDRY, October 17th, 1876.

Messrs. NEYLAN & YOUNG, San Francisco,

Agents for "PICKERING GOVERNORS."

Gents:—The 10 two-inch Improved Speed Adjusting Governors I bought of you this year for my patent Straw Burning Threshing Engines give splendid satisfaction. They far surpass for regularity of speed any Governor that I have ever seen, and I have seen all the best kinds. I have seen the main belt fly off the pulley several times this season while threshing, and the engineer did not discover it, so perfectly was the speed maintained, until he was told of it; this I consider something wonderful; I consider the Governor absolutely perfect, so far as speed is concerned. I bought and put on to one of my engines a Shive Governor, to see which was the best, and after one season's trial I have no hesitation in saying they are far superior to any other Governor that I have seen or used. I wish you would send me the lowest price that you can furnish 25 Governors for next season's engines.

Yours respectfully,

J. L. HEALD.

The only Governor that has received awards at each of the International Exhibitions. American Institute Fair, New York, 1865, Two Medals; Mechanics' Institute Fair, Baltimore, 1865, Silver Medal; American Institute Fair, New York, 1869, Two Medals; International Exposition, Paris, 1867, One Bronze and Two Special Medals; International Exposition, Vienna, 1873, Medal of Progress and Decoration; International Exhibition, Philadelphia, 1876, Medal and Diploma.

PATENTED
CAST STEEL SHOES
AND DIES.

Guaranteed Cheaper than the Best Iron.

IMPORTANT NOTICE.

Reduction in Price from 16 Cents
to 12 Cents Per Pound.

Owing to our largely increased business, the present low price of Iron from which our Steel is manufactured, and the improved facilities for casting and forging, we take great pleasure in announcing that from and after this date we will supply our IMPROVED CAST AND FORGED STEEL SHOES AND DIES FOR QUARTZ MILLS at twelve cents per pound, delivered at San Francisco or Sacramento, instead of sixteen cents, as heretofore.

We also furnish Steel Plates for Blake and other Ore Crushers, Steel Gut Gearing, etc., for Mills and Hoisting Works, Steel Pan Shoes, Battery Cams and Tappets, etc., etc.

Address all orders, with dimensions or drawings, to

CAST STEEL SHOE & DIE CO.,

59 Nevada Block, S. F.

ASBESTOS COATING

For Steam Boilers, Pipes, etc. Best non-conductor of heat in use. It effects a LARGE SAVING OF FUEL, LASTS AS LONG AS THE IRON to which it is applied, and is reasonable in cost.

\$1,000 Challenge Ore Feeder,

AWARDED FIRST PREMIUM

At the Tenth Industrial Fair of the Mechanics' Institute.

It may be considered as now fully demonstrated, by careful and long-continued experimentation, that the plan upon which a perfect ore feeder must be constructed is that of the carrier, and not that of the shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply dropped. Spasmodic or jerky contrivances will not answer the purpose.

REFERENCES.

A letter received from the Julian Mill, Newcastle, says of the Carrier Feeder: "It is the most perfect Feeder we have ever seen; don't see how any mill can do without them."—A letter from Mr. C. C. Belding, of Amador County, speaks in the highest terms of them.—Two of the machines were shipped to the Bunker Hill Mill, also Gover Mill, Amador County.—Mr. Stevenson, of Boston Mill, Gold Hill, Nevada, says they are the best Feeder he has ever seen.—Sousley Mill, Tuolumne County.—California Company, Nevada City.—Omaha Gold Mining Company, Grass Valley.—St. Patrick Mill, Placer County.

\$1,000 CHALLENGE.

Backward in Coming Forward.

C. P. Stanford Fails to Come to Time on the Challenge of \$1,000 to Test the Merits of His Ore Feeder as Against Mine. The Challenge is Still Open to Him or any one else. GENTLEMEN, Put up or Shut up.

A letter has been received from the Crescent mine, Plumas County, in which it states that the Tulloch is a failure as against the \$1,000 Challenge Feeder of Hendy's.

We warrant the machines to give perfect satisfaction, and to be a better and more durable Feeder than any other in the market, and will sell them as cheap as any other of its class.

WEYRAUCH—IRON AND STEEL.

Strength and Determination of its Dimensions with Reference to Latest Experiments. By Prof. J. J. Weyrauch, of Stuttgart, Translated by Prof. A. Jay DuBois, of Lehigh University, with an appendix by Prof. R. H. Thurston, of Stevens Institute. 1 vol. 8vo, with four folding plates, \$1.00. Published and for Sale by JOHN WILEY & SONS, 15 Astor Place, New York. Mailed and prepaid on receipt of price.

The Mechanics' Fair Daily.

By authority of the MECHANICS' INSTITUTE, OF THE CITY OF SAN FRANCISCO, the publishers of the MINING AND SCIENTIFIC PRESS will issue a large edition of the EIGHTH VOLUME of the MECHANICS' FAIR DAILY during the TWELFTH INDUSTRIAL EXHIBITION.

It will be of large size, printed and circulated FREE in the Pavilion, and contain the day and evening programme, and official bulletin of the Institute.

Its columns will embrace a large variety of important industrial and scientific information, illustrations and well written descriptions of the general features and most deserving and novel exhibits in the Fair, a record of the Fair and incidents of its daily progress—gay, serious and comic—as they occur.

The best of editorial, reportorial and corresponding talent will be employed, with a view to make the paper of live interest in all its departments and of standard value as a full record of the great exhibition, the wonderful inventions, rich resources and rapid progress of our great Western community.

Doubtless more than ONE HUNDRED THOUSAND different individuals will receive copies of our paper during the Fair. The fair character of the journal—the specially attractive features of its free issue in the Pavilion, and its absorbing interest to visitors at the Fair, the attention its columns command when brought into the shop and family circle by those who receive it freely at the Fair, make the paper a powerful advertising medium.

The managers have granted us the exclusive advertising and printing privileges and will receive no advertising in the official catalogue and reports.

Our previous volumes have met with unrivaled success and gratifying results to advertisers, nearly all of whom were leading and first-class business firms.

Many thousands of marked copies were sent by mail and otherwise to friends near and distant, giving the FAIR DAILY a more broadcast and universal circulation than any other newspaper published.

Its columns are more closely examined throughout than those of any ordinary publication.

By past experience, ample facilities, and a fair reputation of doing business in our line, we expect, with the reasonable support of all naturally interested in the success of our enterprise, to make the coming volume superior to its predecessors, and eminently satisfactory to the Institute, to our patrons and to the general public, who are more or less benefited by such an advocate of the substantial advancement of the grand and worthy industries of our Coast.

Number 24.

Pavement of Sluices.

Sluice boxes are the highways upon which hydraulic mining is carried on, and their greater or less efficiency has an influence upon this business like that of the establishment of railroads or common wagon roads, upon general commerce. Just as, by the cheapening of carriage, railroads open coal fields, grain producing regions, etc., to the markets of the world, and to a brisk commerce, where common wagon roads would hardly sustain a weak home trade, so well adapted sluice boxes will render inferior gravel deposits paying institutions, while on the other hand rich gravel deposits without proper facilities are worked at a loss. The great requirement is, of course, sufficient grade, but a very great deal also depends on the construction of the sluices and the methods adopted to catch the gold in the bottom as it passes down with the stream of water and debris.

The proper paving of the bottom of sluices is of paramount importance, and various methods are in vogue. Fig. 1 of the engravings on this page shows a plan greatly used, which was described by us some time since in the article by Chas. Waldeyer taken from the report of the United States Mining Commissioner. The bottom shows the rock pavement, the thick streak across the plank shows the plank lining on the sides. Fig. 2 shows the block pavement so universally used in sluices. These blocks are sawed, and set on edge and laid across the flume close together, forming a pavement which prevents wear and also numberless riffles in which to catch the gold. These blocks wear out more rapidly, however, than one would suppose, and have to be frequently replaced.

Recently considerable improvement has been made in the construction of these sluice pavements and different material has been introduced. Condemned car-wheels have been broken up and placed in the bottom of the sluices and are found to answer the purpose excellently, as the numerous irregular crevices make first rate riffles and the bottom is not quickly worn out. Old railroad iron is also used to a considerable extent and is found to be far superior to wooden blocks. An instance showing the superiority of this kind of pavement over the blocks, was shown in a recent experiment carried out at the Morning Star claim, at Iowa Hill. They laid out three sections of the flume, of equal length, (about 65 feet each,) and at a sufficient distance from the bank so that the flume would always run clear. The first section, nearest the bank (about 300 feet distant) was made with the ordinary wooden block pavement. The second section was laid with old iron rails, and the third with wooden blocks similar to the first. On cleaning up they gathered nine ounces more gold from the section laid with railroad iron than from the other two sections put together. This test was made very carefully and shows the superiority of the rails as riffles.

The rails are laid lengthwise the flume, but when in long lengths scantlings have to be spliced on to keep them in position, as they are apt to spring with the vibration caused by big rocks passing over them. The efficiency of this bottom is increased by putting wooden blocks on the sides of the flume with the rails in the center, slanting the surfaces of the blocks toward the center from both sides.

An explosion occurred in the nitro-glycerine department of the Hercules Powder Works, on the Central road, near Fourth avenue, a little past noon on Friday, resulting in a total destruction of the glycerine house. The hands, about twenty, mostly Chinamen, had just left for dinner, and no person was injured by the explosion, with the exception of one man, whose face was slightly cut by broken glass. About 500 pounds of glycerine exploded and the concussion was so great that windows were broken in houses nearly a mile distant. The Superintendent was absent at the time and cannot account for the explosion.

It is stated that contracts have been closed for the construction of six boats or dredgers, to be worked under the patents of the California Dredging and Mining Company.

Holding Door-Knob Screws.

Nearly every one has experienced the annoyance and inconvenience consequent upon door-knob screws becoming loose and falling out, especially in older houses; the screws are lost, the knob and spindle pulled from the door, and the knob on the other side falls and is often broken; a not uncommon occurrence, as many a person can testify, and very annoying, especially when it happens at night and in the dark.

The accompanying illustration shows a simple little device which can be applied to any knob

DEVICE FOR HOLDING DOOR KNOB SCREWS.

in a few moments, and which most effectually cures the evil; permanently securing the knob to the spindle and scarcely noticeable when in position.

It will be seen that it consists of an elastic band of metal, slitted at A, and provided with a small tongue, B, which enters the nick in the head of the screw. The device is applied in

causing the contact points of one or more telegraphic wires to traverse the surfaces in parallel and approximate lines, the inventor can automatically transmit the matter represented by said forms, to distant stations, where the letters or characters can be reproduced by a suitable recording instrument. The principle object of the invention is to permit the conversion of

SLUICE USED IN HYDRAULIC MINING.

the following manner: The screw being first screwed up hard, the position of the nick in its head noted, the tongue in the band is then punched in a corresponding position by a special pair of pincers; the band is then sprung open, passed over the shank of the knob, the tongue, B, introduced into the nick in the screw, and the band allowed to close. The parts then appear as in Figs. 1 and 3, the latter being a section through the shank. Once in position, neither the band nor the screw can turn. For further information, address DeC. May, 42 Mt. Vernon Place, Baltimore, Md.

The aggregate Internal Revenue receipts for the fiscal year to date have exceeded the total receipts for the same period during last year. The returns already foot up an excess of \$111,000,000, and the impression at the Department is that full receipts for the year will fall little, if any, below the estimate of \$120,000,000.

An important sale at auction, by Maurice Dore & Co., of Eureka Lake and Yuba canal company's stock, took place Tuesday, some 7,784 shares being sold, which realized \$176,004, an average of \$22.60 per share.

Typographical Transmitter for Automatic Telegraphs.

Mr. Loring Pickering, one of the editors and proprietors of the *Daily Evening Bulletin* and *Daily Morning Call* of this city, has just obtained a patent through the MINING AND SCIENTIFIC PRESS PATENT AGENCY, for a method of rapid telegraphing, which is of great value for the transmission of dispatches for newspapers. The patent covers a method for converting type forms and other raised or engraved characters, into transmitting plates, so that by

and operating the improved typographical transmitter, are both ingenious and simple. The invention can be applied to either curved or flat type forms.

A stereotype cast is taken from the ordinary newspaper form. The spaces between the types on the plate are filled with some non-conducting material, so as to insulate the faces of the type from each other and render the surface smooth and even. A filling of shellac, or any other non-conducting substance of the consistency of putty, such as can be applied readily, either warm or cold, will answer. After the filling and smoothing has been completed the faces of the types can be slightly sand-papered to free them from any adhering portion of the substance. The type plate can then be put in circuit by connecting one of the battery wires with it.

It will be evident that the inventor will now have a metallic type plate in which the surfaces of the type are exposed in regular order, just as the types were originally set up, and with which it is only necessary to make the proper connections to transmit a facsimile copy to the opposite end of the contact wire or wires.

The line over which the matter thus produced is to be transmitted is composed of several parallel wires. Each wire has a point or style at each end. The several points are then arranged in a spiral manner so that they will trace in lines close together, thus practically forming a brush which sweeps over the face of a cylinder or flat plate at each end of the line, according to the form of matter to be transmitted. The prepared plate is then mounted upon a suitable support—usually a cylinder—at one end of the line, and put in the electric circuit, while a similar cylinder at the opposite end of the line, around which sensitive paper has been wrapped, is also mounted so as to be swept by the other set of fingers.

The cylinders are then rotated synchronously by suitable means so that the fingers at one end will sweep over the surface of the types. Each time a finger comes in contact with a type face the electric circuit is completed and the corresponding finger at the opposite end of the wire makes a corresponding mark on the sensitive paper, but when the finger leaves the type face the contact is broken and the fingers are negative. Either the cylinders can be moved endwise by suitable means under the fingers or the fingers can be moved over the cylinders; in either case a few rotations of the cylinders completes the transmission and the entire newspaper or other form is reproduced in exact facsimile upon the sensitive paper at the other end of the line. This system is quite simple and a whole newspaper page can be transmitted by telegraph in from fifteen minutes to half an hour, delivering the copy ready for the printers, so that there is no necessity of copying it again.

THE LAVA BEDS.—We mentioned the fact in our issue of last week, that the Chinamen were at work in large numbers on the "lava beds," near Oroville, Butte county, and were making money. We did not know then exactly to what extent they were taking out gold, but the *Oroville Mercury* gives us the following information concerning the claims: The first claim on the right hand side of the river road, going down, yielded \$1,645 worth of gold last week. The claim bought of Robert Gordon yielded \$5,508 last week. There are five other large claims that have steam pumps at work on them, and we may safely conclude that they yield at least \$10,000 per week. There are also many other claims that are paying very well; but we have no means of knowing what they do pay. The figures of the two referred to came from the house where the dust was sold and are correct. They send their own dust to the mint themselves, thus making every cent that it is possible out of it.

FRUE CONCENTRATOR.—A trial of the Frue concentrator, which we illustrated and described in detail some time since, was had at Joshua Hendy's this week. As we have before stated, these concentrators are proving very successful with the gold sands of our northern coast, heretofore found very difficult to work. It is shortly to be tried on Comstock tailings.

Block Pavement for Sluices.

are usually quite small, when compared with the types heretofore used in automatic telegraphing, a peculiar arrangement or adjustment of the contact points is necessary where several wires are used, in order to permit the several points to trace in lines sufficiently close together to reproduce the outline of the letter.

Mr. Pickering's method of arranging these points in order to accomplish the object mentioned, together with the manner of preparing

CORRESPONDENCE.

Birds-eye View of Sierra County Mines.

[From Our Traveling Correspondent.]

The yield from the placer and hydraulic mines will be very materially affected by the light snow-fall of the past winter. Drifting will also be cut short in many localities from the same cause. The quartz claims are probably turning out fully as well as formerly. As the sequel will show, some new and valuable ground has been broken for gravel, and at least one recent very rich strike made in quartz. This may be expected to give a fresh impulse to prospecting, and, at the same time, turn the attention of capital a little more in this direction. In view of the many inviting fields offered here for its profitable investment, its magic power has, thus far, been but little felt. There are vast areas of comparatively unexplored ground in different parts of the county—full of promise both for quartz and gravel—that would seem to require only one touch of "its wizard wand" to bring forth from the smitten rocks many a gushing golden stream, giving new life, freshness and vigor, not only to mining operations, but to every other industrial pursuit. Beginning with

The Drift and Gravel Mines

In the northern part of the county; they may be said to be doing as well as could be expected, remembering that Pluvius, the rain-king of the valley, and hoary-headed Nix, of the higher altitudes, have both been less lavish than usual of their accustomed favors.

The North America, at Newark, is working a large force, and said to be doing better than its former years. At Whisky Diggings, a mile below, the Schofield Bros. have recently struck good pay gravel.

The Claims at Gibsonville

Are generally doing fairly. The Union is working 40 white men, and are cleaning up to the entire satisfaction of the company. The hotels are crowded, and the place is one of the liveliest in the county.

Between Port Wine and Scales Diggings there is an extensive scope of country, giving evidence of

Good Gravel Deposits.

That have lain thus far undeveloped, principally for want of capital. One company, the Iowa, has persevered, and after working for many years to little purpose, has at length reached good pay gravel. The company commenced in August last to sink an incline shaft, which has reached bedrock. Gangways are being opened, new and substantial hoisting works will soon take the place of those on the ground, and in the opinion of Mr. A. J. Rigby, the present Superintendent, the mine bids fair to be shortly put on a good paying basis.

The Cleveland Co.

At Scales Diggings, two miles below the Iowa shaft, having been working for several years at a considerable disadvantage, now propose to introduce the Burleigh drill and extend their tunnel into a similar rich deposit on the same channel. Mr. R. N. Williams, the Superintendent, who has been here for many years, has shown his confidence in the ground, although but partially developed, by recently purchasing a large interest.

The Fairplay,

Owned by Boyce Brothers, a mile below, has a bank with an average height of 200 feet, for the full face of 600 feet, 125 feet of which is pay gravel. Flume, 1,800 feet in length, three and one-half in width, eight dumps, and four under-currents. At the head of the flume, sawed riffles are put in lengthwise, instead of block bottoms, being much preferred at this point for saving gold.

The product of the mine, last year, reached \$32,000. Owing to scarcity of water, but little over one-half this amount is looked for the present season. For the same reason, most of the claims at Port Wine, St. Louis and Howland Flat will fall short of the usual amount.

The Empire,

Under the superintendence of Mr. J. P. De Noon, at Howland Flat, is working about 100 men, and is paying as usual. It is well known that it has furnished its regular monthly dividends for the past three years, and promises fair to continue them for some time to come. It is a drift claim, with a very large amount of ground yet to be worked.

In the southern part of the county some comparatively new enterprises have been inaugurated, and work is progressing favorably on most of the gravel claims. A few illustrations will be given before turning to quartz.

A Very Important Experiment

Is about to be tried, and should it prove a success, will revolutionize the gravel operations of the entire State. The progress of the work will be watched, from inception to termination, with more than usual interest. The undertaking is understood to be well backed by San Francisco capital, and the prime movers are full of confidence as to the final result.

The incorporation is known as the

Pliocene G. M. Co.

(E. S. Thurston, Supt.), and has been organized

for the prospecting and working of certain gravel deposits, situated between Downieville and Forest City, and supposed to be the extension of the famous Bald Mountain channel. The proposed new system of working will be by boring instead of tunneling, the object being to define the exact position of the channel before incurring the expense of sinking shafts and running tunnels, which too frequently strike wide of the mark intended, thereby causing long delays and heavy losses. The tools used are designed and manufactured by Mr. Chas. Oester, of San Francisco, and are in most respects similar to those employed in the oil wells of Pennsylvania. The auger is said to bore through clay at the rate of 70 feet in 24 hours, the drills averaging through ordinarily hard rock or boulders about one foot per hour. The channel is expected to be found at a depth of 500 feet from the surface. As soon as its position is determined by the drill a three-compartment working shaft will be lowered, and the requisite machinery erected.

The Bald Mountain

(H. Wallace, Supt.), at Forest City, has been in very successful operation for the past five years, during which it has yielded in the gross some things upwards of \$1,000,000, and paid in dividends more than half of the gross amount, distributing to the stockholders last year as much as \$165,000. The sum estimated for the present year is put at \$80,000, the falling off being attributable to the shortening of the water season. Average width of channel, 500 feet; length of claim, 8,500 feet; 2,200 feet worked out; average depth of pay gravel, three feet, and giving for the whole time an average of \$1 per superficial foot on the bedrock; entire length of tunnel, 4,400 feet. Track, T rail weighing 20 pounds to the yard; gauge, 20 inches; grade, one foot in 24. The power for moving the gravel is a locomotive, manufactured at the Baldwin locomotive works, Philadelphia, and believed to be the only one used for the purpose on the coast. Its entire length is 13 feet, height five and a half feet, width of bottom four feet, and two and one-half feet at top. Anthracite coal is used. No trouble is experienced from gas or steam. The system of ventilation is by shaft 2,000 feet from mouth of tunnel, from the foot of which an air-way extends to the face of the works, the air being accelerated by water-blast, and giving, by this means, to each workman 120 cubic feet of air per minute. The cost of transporting the dirt, some 3,800 feet, is only two and one-fourth cents per ton against 21 cents, as formerly by hand, including besides the hauling of all the material used in the mine, and the men to their point of operations, giving a large saving in both muscle and time, the gain in the latter being 30 minutes per day to each man.

The Mammoth Spring M. Co.,

Of Forest City, have recently struck in their claim, one and a half miles above Allegheny, one of the finest prospects for good permanent pay met with for many a day. The gravel was reached in the shaft 47 feet above a main tunnel of 600 feet in length. A drift has been run 100 feet on the pay streak, which has thus far yielded over half an ounce to the man, gold 950 fine.

There are several other fine locations around both last mentioned places, a detailed account of which must be omitted, as some attention must be given to

The Quartz Claims

Of the county. Fortunately a very natural transition from gravel to quartz is offered in the introduction to the reader of the next claim to be described, as both forms of mining are here happily combined with promise of very rich returns from each. Some rather wild and exaggerated statements, particularly as to the amount realized from the quartz, since its discovery, have made the rounds of the papers, but so far as the richness of the rock is concerned, no mere word-painting, however fine or glowing, could lead to a false impression. It cannot be described. It must be seen and handled to be truly realized. It is scarcely necessary to say that allusion is made to

The North Fork M. Co.'s Claim

At Forest City. An accident led to the discovery. After finding good pay gravel, worth from \$3 to \$10 to the car-load, the swelling of the serpentine, which is the bedrock of the gravel and the formation incasing the ledge, a change in the direction of the tunnel became necessary. This was the lucky tide in their affairs that promises "to lead on to fortune." It has been but a brief period since the tunnel struck what appears to be a true fissure vein from 2 to 6 feet in width, the developments already disclosing a length on its course of at least 800 feet, and a chimney from 75 to 100 feet of ore, that challenges comparison with the richest known. In some large choice specimens, the gold and quartz seem combined in about equal proportions. Bunches of solid sulphurets, with here and there a trace of gold visible, and weighing from 20 to 30 pounds, are represented to assay from \$18,000, to \$20,000 per ton. The gold is carried, largely in fact, in arsenical and iron sulphurets, accompanied with some galena. Near the surface they are often much decomposed, and many thousands have been cleaned up by running the rock and dirt from the ledge through the sluices. The harder rock, particularly the richer specimens, have in the meantime been turned to good account by means of the hand-mortar, two men having pounded out in a week nearly \$8,000. What is still better, it seems to hold out and grow more extensive.

Last night (May 31st,) another very large and rich body was struck in the face of the tunnel. The amount estimated as taken out within the past eight hours, (and the figures, after a close inspection, are fully believed to be within bounds,) will not fall short of \$5,000.

Owing to the prevailing rumors as to its richness, every point of interest about this wonderful mine was visited, under the guidance of the Superintendent, Mr. Watson Bayles, the tendency being to confirm impressions previously received as to the quantity and quality of the ore, as well as to settle more definitely and favorably the question as to its future permanency.

The Empire (B. B. Lewis, proprietor), situated on Kanaka creek, below Allegheny, has been opened by two tunnels running on the vein, the lower to the length of 200 feet, and reaching a depth of 150 feet from surface. It is a small fissure vein, cutting in its course the serpentine and talcose slate. The quartz taken from the upper tunnel, and from a 40-foot shaft from the same, has yielded by hand mortar \$100 per ton. It is at present worked, and all the quartz will pay to mill.

The Plumbago,

(Bovee & Haggerty), is a contact vein, from two to six feet wide, between the trap and the serpentine. It has been worked at intervals the past three years. The total estimated yield from its opening is put at about \$100,000, the most of the rock having been worked by hand mortar; and an instance is reported of two men taking out as much as \$5,000 in a single fortnight.

It is thought that the prospects of the mine would well justify the erection of a mill, if it were once systematically opened, there being no question as to the value of the ore.

The Brush Creek Mine,

At the Mountain house, four miles from Forest City, is also a contact vein, with slate as one wall and serpentine on the other; fissure from two to four feet in width. Although not at present paying, it is said to have yielded in the past not far from a round million. The company are now sinking, having already reached a depth of 520 feet, and hoping every day to strike into the same rich chimney encountered in the upper levels.

Little need be said about

The Celebrated Sierra Butte Mine,

Mr. Wm. John, Superintendent, at Sierra City. The country rock is syenite and greenstone; ledge varying from one to 15 feet; quartz averaging from \$6 to \$7 per ton. Such is the system and economy in the management, and the facilities for mining and milling, that it is understood to be paying a fair profit on the investment. The company have three mills, all run by water power, aggregating 86 stamps, and some 300 men employed directly or indirectly in connection with their mines and mill. This valuable property, including the Independent mine, is said to be now owned and controlled exclusively by English capital.

The Quartz Mines around Downieville,

While in many instances giving evidences of merit, have so far failed in attracting much attention from the outside world. The where-with is the great *sine qua non*, especially in most quartz operations. The want of the necessary means on the part of the owners for the proper development and advantageous working of their ledges, may be assigned as one of the chief causes of their not coming into notice, taken in connection with the fact that all eyes, both at home and abroad for the past four years, have been bewildered—almost blinded—by the more dazzling glare from our great silver bonanzas.

Owing to the inclemency of the weather, personal observation was out of the question, but the facts as gleaned from the citizens may be taken as substantially reliable.

The Good Hope

Is situated just above the town; general direction, north and south; dip, west; western wall, serpentine; eastern said to be a species of dark gray sandstone; average width, four feet; quartz—one stratum described as of a rusty, reddish cast; another, of a bluish white. The best rock paid by working process, \$23.86; the poorest, \$9.50, averaging \$12 per ton. The tunnel strikes the ledge at a depth of 140 feet from surface, making connection with the air shaft. There is good water power at hand for a 20-stamp mill. The mine has been recently bonded to Mr. H. K. Wilson, a fact understood here to mean business.

The Leonard,

South of the Good Hope, and opened by a tunnel, is represented as a large lode with four feet of good ore at present depth. It has given working tests of \$17 and upwards to the ton. In the neighborhood of \$300,000 is reported as realized from the mine, but a new tunnel will be required before more quartz can be profitably extracted. A 12-stamp mill, driven by water power, is connected with the property.

The Claim of the Oro Gold Quartz M. Co. Is situated in the suburbs of the town, only 1,200 feet from the river, where there is ample power for any required number of stamps. It lies in the slate range, but is bounded on one side by greenstone. The developments are by two tunnels, one of 425 feet in length and attaining a depth on the ledge of 300 feet. Width of main vein averages four feet; quartz, matrix, highly impregnated with gold-bearing arseniurets and sulphurets of iron, somewhat oxidized and decomposed near the surface.

From \$12,000 to \$13,000 have been worked by arastra, the quartz crushed coming princi-

pally from a feeder to the ledge, and averaging \$10 per ton, some of it running to \$15. The ore of the main ledge is estimated to work from five to six dollars per ton, and is considered sufficiently promising, in view of the water facilities, to demand the erection of a mill.

Work is said to be progressing on the Monte Cristo tunnel, four miles from Downieville. At the depth of 100 feet, the ledge is 10 feet wide and the ore taken from shaft has worked, mill process, \$22.60 per ton, the gold being well diffused through the rock.

The Dollyarden,

Seven miles southeast of Downieville and owned by citizens of the place, is represented to be from four five to feet in width; in a slate and granite formation; shaft 40 feet and drift on vein of 50 feet.

In addition to the working of \$2,500, principally by hand mortar, some 2,000 pounds were sent to Nevada City as a working test, that yielded \$275 per ton as per certificate of assayer, the tailings assaying at the rate of \$18 per ton.

Some very rich and beautiful specimens from the mine were seen in one of the principal saloons of Downieville, so that taken all in all, it looks like a prospect well worth following up.

The Gold Bluff quartz mine, situated within a mile of Downieville, has been worked somewhat spasmodically since 1856; opened by tunnels, the longest gaining a depth on ledge of 700 feet. It varies in width from two to 20 feet, one wall talcose slate, the other granite. The rock has averaged throughout eight dollars per ton. Above \$12,000 were taken out the past spring. It seems to need only "a strong pull, a long pull and a pull all together," to make it a steadily paying mine. A. C. K.

Calaveras County Mines.

[From Our Regular Correspondent.]

EDITORS PRESS:—Calaveras mines are generally being looked after, and here and there are some new developments being made by local and San Francisco capital. These movements are of the quiet order, and speak all the louder for real business.

The Sheep Ranch

Gets its name from being used in 1859 by Messrs. Simpson & Thompson as a sheep range. In 1868 quartz was discovered by Mr. Childers and son, but the bringing out of the camp is mostly due to the energy of Capt. Fergusson, now in San Andreas. It was first tested with arastra, which paid very well; now running by water power a five-stamp mill and a new 10-stamp mill is being erected. The mine employs 30 men—all white; ledge three to six feet thick, solid quartz mostly, average pay very encouraging. Working at depth of 200 feet. Water is easily kept out with six-inch pump, lifting about four inches water, which is used to good advantage for irrigation. The mill and mine are under the supervision of W. A. Wallace, of whose management all seem to speak in the highest praise. The air of honesty was quite refreshing, and, by contrast, very noticeable. No signs stuck up to warn off from the dump, where the gold glittered in and on the rock, yet no one uninvited would go near that dump, though not enclosed.

The city contains two or three stores, two saloons, a boarding house and hotel by Charles Anderson, an early settler. Some have desired to change the name, as Sheep Ranch City would not give glory to a great town; but then some think it bad luck to change the names of children, and are not willing to risk the rashness of changing Sheep Ranch for Andersonville, Goldopolis, or any other selected name. They are satisfied that the mineral they have in the vicinity, and only mine development will necessitate a town.

Railroad Flat,

Though only the quiet shadow of its former self, has several promising features of a future life. The Buena Vista, with water power hoisting and pumping machinery, are progressing finely; are down on the incline about 150 feet and drifts out on ledge 100 feet, each in opposite direction; ledge, 20 inches of average good ore; some hydraulic mining yet going on in the vicinity.

The Fern mine, two miles southwest of Railroad Flat, is being prospected by San Francisco parties, who are erecting a small mill and putting up one of Wilcox's latest improved single pumps, whose trial working was made while I was present, and seemed very satisfactory to all concerned.

This is an old mine, owned by Mr. Chapman and others, but had not been tested. Mr. Kimball, who is putting up the present machinery, and is down 125 feet, seems well satisfied with the assurances as now indicated of a good mine.

Woodhouse & Anderson Flat

Mines are also being prospected by San Francisco men, with direct reference to a purchase of same, in connection with the Harris mill—an excellent ten-stamp water mill, about two miles from Railroad Flat, situated in the midst of some very valuable small ranches, that enjoy some benefits from the water after it leaves the mill.

I would like to mention many prospecting op-

Continued on page 383.

MECHANICAL PROGRESS.

The New German Patent Law.

The new German Imperial patent law was passed by the Reichstag last month and will come into force on the 1st of July next. The new law puts an end to the disorder concerning patents in Germany, that has existed until now, there being at the present time 21 different States granting patents of their own. These will be embraced by one law after the 1st of July. Our English exchange, *Iron*, has had opportunity to examine the new law and gives the following abstract of its provisions: Pharmaceutical compounds, medicines, alimentary preparations, and chemical products cannot be patented under the new law; processes, however, by which these articles are obtained, can be patented. An invention must be novel and not have been introduced to the public, so that another person can imitate the same. Imported inventions are patentable only to the real inventor. Foreigners must be represented by a German citizen. It is unlawful to manufacture a patent article, to import the same from another country, or even to use without permission a patented machine, tool, apparatus, or process. Any one having an invention in use cannot be prevented from continuing to use the same. A patent remains good for 15 years; the duty is 50 marks (£2 10s.) for the first year; 50 marks (£2 10s.) for the second; 100 marks (£5) for the third, and so on, with an addition of 50 marks each year; thus a 15 years' patent costs 5,300 marks (£265). The duty may be paid three months after date. Patent rights may be withdrawn by the government after three years if the invention has not been carried into operation to a proper extent, or if the inventor has not taken the necessary steps to carry the patent into effect, if he refuses licenses to others who offer a fair royalty, or if it is advisable for the public good to grant such licenses. When the invention or improvement relates to purposes of war or marine, or affects the general welfare, a patent will not be granted, but the inventor will be recompensed by the State. The decision in this case will rest with the Imperial Chancellor. Any one having obtained a patent for improvements on a patented article, and wanting a license from the first inventor, is obliged to give the latter a license for his improvements. The applications will be examined by the Patent Commissioners and experts appointed for this purpose; an appeal can be made, in case of refusal, to a special commissioner, and from him to the Imperial Court at Leipzig. In the case of poor inventors, the payment of duty will be postponed for two years, or may be altogether remitted. Specifications and drawings can be inspected immediately after the application; on account of this, patents should be taken in other countries first. Patents being delivered, a short specification of the same will be published in the *Patent Journal*. Before the lapse of a patent, notice has to be given to the inventor, and a proper time allowed him to fulfil the requirements of the law. Infringements of patent right are punished with a fine up to 10,000 marks (£500), or imprisonment not exceeding one year. Marking articles as patented which are not so, is punished with a fine of 150 marks (£7 10s.) At the publication of the invention, any one thinking he has a prior right may enter an opposition, which is then examined in the presence of those concerned. Existing German patents may be transferred to the Empire, but cannot be prolonged.

ROLLING HOOP IRON.—To produce a superior finish and improved quality of hoop iron, and to save the labor in its manufacture, the *American Manufacturer* says that Messrs. Jones & Cook, of Rotherham, England, fix a pair of rolls at the back of the ordinary set of "strand" or grooved rolls, and revolving in the same direction as the middle and bottom strand rolls, with which they correspond in height. A guide is fixed from the back of the first pair of rolls, and passes between the middle and bottom strand rolls, curving round and upwards to the front and entrance of the top and middle rolls. The rolls of the first pair are speeded to suit the draw of the iron in passing through the top and middle strand rolls, so as to avoid forming a large loop of the iron between the two pairs of rolls. The iron, on passing through the first pair of rolls, is forced along the guide through the groove underneath the middle strand roll, and following the shape or curve of the guide is directed upwards to the proper groove between the top and middle strand rolls, thus dispensing with the services of a "turn-over," and finishing the iron in a much hotter state than is possible by the present slower process.

NEW FILE.—A rat-tail file, the teeth of which are cut on spiral ribs, with grooves between to facilitate clearing, is the subject of a recent patent. It is made by twisting a fluted bar of steel, and then cutting teeth on the spiral ribs so formed.

STEEL HAWSER.—A steel wire hawser, 150 fathoms long and 1½ tons in weight, has been supplied to the iron-clad frigate *Alexandra*. When coiled it occupies a space 4½ feet by 4½ feet. A hemp hawser would be double the weight and occupy six times the space.

How to Galvanize Iron.

Galvanizing iron sheets is quite an industry by itself and the product can be bought cheaper than it can be made on a small scale. There are, however, times when it is worth while to coat small articles of iron with zinc to prevent rust, etc., and the description of a way to do this may be valuable to some of our readers. The *Iron Age* has lately had occasion to examine the processes and gives the following: The articles are to be first cleansed by placing them in open wooden vessels, in water containing three-quarters to one per cent. of common sulphuric acid, and allowed to remain in it until the surface appears clean, or may be rendered so by scouring with a rag or wet sand. According to the amount of acid, this may require from six to 24 hours. Fresh acid must be added according to the extent of use and of the liquid. When this is saturated with sulphate of iron it must be renewed. After removal from this bath the articles are rinsed in fresh water, and scoured until they acquire a clean, metallic surface, and then kept in water in which a little slacked lime has been stirred until the next operation. When thus freed from rust, they are to be coated with a thin film of zinc while cold, by means of chloride of zinc, which may be made by filling a glazed earthen vessel of about two-thirds gallon capacity three-fourths full of muriatic acid, and adding zinc clippings until effervescence ceases. The liquid is then to be turned off from the undissolved zinc and preserved in a glass vessel. For use it is poured into a sheet zinc vessel of suitable size and shape for the objects, and about 1.30 per cent. of its weight of finely powdered sal ammoniac added. The articles are then immersed in it, a scum of fine bubbles forming on the surface in from one to two minutes, indicative of the completion of the operation. The articles are next drained, so that the excess may flow back into the vessel. The iron articles thus coated with a fine film of zinc are placed on clean sheet iron heated from beneath, and perfectly dried, and then dipped piece by piece, by means of tongs, into very hot (though not glowing) molten zinc for a short time, until they acquire the temperature of the zinc. They are then removed and beaten, to cause the excess of zinc to fall off.

A New Swiss Boring Tool.

An improved drill for iron and other metals, patented by Mr. Jacob Jaggi, at Frauenfeld, Switzerland, is constructed of all sizes, and made from best rolled and hardened cast-steel; it has two even or "cutting faces," and two hollow faces (concaves). The even face has for dimension the breadth of the radius, plus the half of the medium thickness of the drill, the other round face being as large as the radius. The stock for holding the drill consists of the stock or boring head block cast on the boring engine, or secured thereto. This stock or boring head is purchased or recessed on its lower end for introducing in it the different kinds and sizes of drills, the said boring head being supplied with two cheeks, the one placed opposite the face of the other, and around these cheeks is placed a band or hoop in which is turned side by side of the cheeks two eccentric openings, which correspond exactly with the cheek faces. On turning this hoop by means of a hook or key the cheeks will become fast on the hoop and the drill and hold the latter firmly in the boring head or stock. The advantages claimed to arise from the use of this improved boring tool are—that the entire length of the borer can be utilized without being dressed and hardened during use; that for about 15 sizes of drills one stock will suffice; that these drills may be arranged to be used on both ends; that the drill is quickly enclosed and immediately dressed in the right position; that the friction on the drill is reduced to a minimum; that these drills do not wear so rapidly as those now used; that they are comparatively strong in proportion to their weight; that they can be easily ground; that the boring chips leave the bored hole easily, whereby the boring of deep holes can be executed without heating the drill much, and the lubrication can be easily effected; that a round and smooth hole is produced; and that the tool is very cheap.

A NOVELTY IN RAILWAY CONSTRUCTION.—It was until recently the intention of the Boston, Winthrop and Point Shirley Railroad Company, to use 40 pound T rails, but the *Iron Age* says that after investigation and by indorsement and advice of several of the best railroad engineers it was decided to use 20 pound Angle rails, bolted to substantial wooden stringers, which are placed upon ordinary ties, and by which dangers proceeding from broken rails are avoided, and a large saving made in cost of construction. We believe the "Angle" rail is named after its inventor, Mr. Angle, of Chicago. The employment of the stringer or sleeper is a novelty in modern railway practice, we think. Formerly sleepers as well as ties were used, and some marked advantages were claimed for them over the plan of using cross ties alone. A new form of rail may develop the advantages of sleepers over ties, and give us a new method of construction which shall have the good points of each.

STEEL GRAIN CARS.—A statement is going the rounds of the papers that the Grand Trunk Company is having a number of grain cars built which are largely composed of steel. These cars, it is said, weigh six tons only and are to have a carrying capacity of 18 tons.

SCIENTIFIC PROGRESS.

DURABILITY OF ALUMINIUM.—At the late reception of the S. F. Microscopical Society a first-class instrument was shown of which the material used was aluminium. It was greatly admired and the fact calls to mind the fact that Dr. C. Winkler of Freiberg has recently made some interesting observations on the resistance of aluminium to atmospheric influences and chemical action. Aluminium has always been regarded as a metal possessing but little resistance to exterior influences of change, and that it would readily be attacked by both acids and alkalis. The relative cost of zinc, aluminium and silver are as 1: 200: 400; or, considering the weights of the metals named, as 1: 67: 530. To test in practice the comparative wearing qualities of aluminium, Herr Winkler has made a number of spoons respectively of silver, pure aluminium and German silver. A spoon of each material above named was accurately weighed on February 1st, 1876, and all were put into daily use under precisely similar conditions for the period of one year. The color of all the metals altered in the lapse of time. The aluminium lost its luster and became a dead, bluish-gray color; the German silver also degenerated to a grayish-yellow tint; the silver lost only in color, its luster was not impaired. As regards mechanical abrasion, no marked difference was perceptible, although after a year's use the aluminium spoon showed marked traces of wear at the edges. By accurately weighing the spoons at the end of the period named, Herr Winkler was enabled to establish the fact that the loss of weight suffered by the spoon of silver was 0.403 per cent.; by the aluminium spoon, 0.630 per cent.; and by the German silver, 1.006 per cent.

From this fact it appears that the assertion that aluminium is unsuited to sustain wear is not borne out. Upon the question of the adaptation of aluminium for coinage, Herr Winkler expresses a favorable opinion—so far as the wearing properties of the metal are concerned.

VELOCITY OF LIGHT.—The 13th volume of the "Annales de l'Observatoire de Paris," contains the memoir of M. Cornu on the determination of the velocity of light, embracing a complete recital of the experiments made in 1874 between the observatory of Paris and the tower of Montlhéry. Everything was done to obtain the greatest possible precision, by perfecting the method of the toothed wheel, which was devised by Fizeau in 1849. The method of observation, the construction of the various articles of apparatus and their mode of acting have been discussed in their most minute details, with a view to ascertain the causes of error, and to determine the most favorable conditions for their elimination. The agreement of results obtained under the most varied circumstances, shows the importance of this discussion. Care was taken in all cases to prove that the deviations followed the law of accidental errors, a verification which is commonly neglected, but without which the calculus of probabilities cannot be legitimately applied. The result of the experiments gives, for the velocity of light, 300,400 kilometers per second. This gives for the solar parallax, 8.88", if we adopt Delambre's equation of light, (493.2s) or Bradley's constant of aberration, (20.25"), 8.80", with Struve's constant, (20.445").

MOUND BUILDERS.—At the last meeting of the Philadelphia Academy of Sciences, Mr. John Ford described a group of eight burial mounds opened by him near Coup's creek, Macoupin county, Ill. Each of the graves was lined with stone slabs, and after the bodies were placed in position within, earth had been packed around them so as to fill the inclosure. All the skeletons found in these graves faced the east. In one of the graves four skeletons were found, seated in two pairs, the knees of one pair pressing against the backs of the other. The arms were crossed. In the right hand of each individual thus interred, a large marine shell (*Buccinum pernervum*, Linn.) had been so placed that the small end of the shell rested in the hand and the large end in the hollow above the left hip. Within each shell what appeared to be the bones of a child were found, whose skull had been crushed before burial, the skull protruding beyond the aperture of the shell. It is thought that these infants were sacrificed to the dead. In most of the graves the left side of the skulls of the adults appeared also to have been crushed by some blunt weapon.

SOURCE OF ELECTRICITY IN LIVING BODIES.—It is requisite that a few words should be said relative to the source from whence the electricity in the system is derived. With every breath of air which our lungs inhale, the venous blood is not only oxidized and transformed into arterial blood, but it is also charged with electricity, produced by the condensation of the air, which takes place by the pressure through the bronchial tubes of the lungs, during the act of exhalation. That this is actually the case is proved by the experiment of Dr. Kincke, of Berlin, showing that currents of electricity are engendered by pressing an aqueous liquid or damp air through a membrane of bladder, or silk, or even through a diaphragm of sulphur in a powdered state; the greatest quantity of electricity, equal to that generated by a Daniell element, being yielded by the latter.

POINT OF FUSION.—A new method for determining exactly the point of fusion of bodies has lately been described by M. Himly. The *English Mechanic* says: The principal part of the apparatus is a thermometer, whose reservoir, of elongated form, is silvered by means of tartrate of silver and ammonia. A copper wire, connected with this layer of silver, permits of placing the thermometer in an electric circuit. For good conducting bodies this layer is strengthened by a deposit of galvanic copper. The substance to be examined is placed in the form of small bars in one of the branches of a tube. A metallic wire is inserted in this branch. In the other is the thermometer. The apparatus and an electric bell are placed in the circuit of a battery. You heat slowly, by means of a bath of mercury or any alloy, and note the temperature when the bell begins to ring. For substances which fuse at a high temperature, a little fusible tube is taken, and a suitable pyrometer. Badly conducting bodies are first fused, then the bulb of the thermometer is immersed in them once or oftener, so that it is covered with a thin layer. You then introduce the thermometer into a tube, placed in the circuit, containing mercury, and heated in a bath of glycerine, or a mixture of glycerine and chloride of calcium. The bell again indicates the commencement of fusion.

RESURRECTION OF ILMENIUM.—In a recent issue of *Nature* we find some interesting facts concerning two new metals, Ilmenium and Neptunium, which may be summarized as follows: About 30 years ago, R. Hermann announced the discovery of a new metal, ilmenium, accompanying tantalum and niobium in various minerals, and closely allied to them in its general characters. Several years later he relinquished his claims to the discovery in consequence of researches by Marignac in the same field leading to entirely different results. Later investigations have, however, strengthened his belief in the existence of ilmenium, and in the February number of Kolbe's *Journal für praktische Chemie* he not only brings forward results tending to establish the individual character of ilmenium, but describes a new metal, neptunium, belonging to the same group and occurring in tantalite from Haddam, Connecticut. As the quantities obtained are small, the characteristic reactions limited, and as the spectral properties cannot be made use of, chemists will naturally reserve their opinion till confirmatory observations have been made by some other well-known investigator.

CURIOUS PHENOMENON WITH PALLADIUM.—In the year 1824, says *Nature*, M. Wohler made the observation that palladium, whether in the form of sponge or of polished sheet, has the property of becoming sooty in a spirit flame, and gradually coated with a thick layer of carbon. A piece of spongy palladium will thus be enlarged to several times its original volume. The same phenomenon occurs if the metal is made to glow in a coal-gas flame. If the deposited carbon be burnt, there always remains a fine skeleton of palladium, which is then found to be penetrated with the carbon and quite brittle. By more recent experiments M. Wohler convinced himself that the phenomenon is not due to a special affinity of palladium for carbon. He is rather of opinion that the strong absorption power of this metal for hydrogen is the reason why ethylene gas and the gases of the spirit flame, which themselves are not absorbed by palladium, are decomposed under the influence of this metal, as the experiments show, with separation of carbon.

SUN SPOT CYCLES.—In attempting to establish connection between sun spots, cyclones and rain-fall in India, Mr. Henry Jeula, a resident of that country, says that it is pretty well known that the maximum and minimum of sun spots alternate in cycles of about eleven years; and the figures given establish that about the minimum periods there have been droughts in India, followed by famine. Although the losses of ships do not exhibit the same regularity, there are indications that the periods of minimum disturbance on the sun's atmosphere are reflected in that portion of the world in destructive cyclones.

MARINE SOUNDING-LINE.—Mr. Ch. Tardieu employs a spherical envelope of caoutchouc, communicating with an iron reservoir by means of a small tube which is provided with a valve. The envelope being filled with mercury, any increase of external pressure forces into the reservoir some of the mercury, which cannot return on account of the valve. The weight of the mercury determines the pressure, and consequently the depth of the water.

SPECTRUM OF ELECTRIC LIGHT.—M. P. Desains finds that the spectra of electric light are very similar to those of the solar rays. They are less extensive, particularly on the side of the violet; but the curves of intensity exhibit but slight differences in the region of greatest heat.

PROGRESS IN ENGLAND.—In 1853-54 the estimate for education, science and art in Great Britain was £378,000; this year the estimate reaches £3,546,000.

Cutting Uncle Sam's Timber.

A few days ago the telegraph brought news of a heavy verdict gained by Uncle Sam against parties who had been cutting timber on public lands in Louisiana contrary to the law. We have information that similar encroachment has been practiced in several parts of this State, and we are advised that the United States Land Office at Washington will take charge of the prosecution of those guilty of the depredation. An official circular from J. A. Williamson, Commissioner at Washington, gives the Land Offices in this State the following instructions in the matter. Whether the department at Washington think its men can be sharper in pursuit of the depredators than the local land officers, we do not know, but it is evident that the department means business in the premises.

For the information of all we quote from the circular, alluded to above, as follows: The Secretary of the Interior has concluded to change the method formerly adopted for protecting the timber on the public lands, by which you were made agents for that purpose within the limits of your respective land districts as per circular of December 24th, 1855. Pursuant to the directions from him of the 5th ultimo, the instructions of that circular are hereby revoked.

Hereafter, as it may be found advisable, from time to time, for the end in view, clerks or employees will be detailed from this office to act under instructions of the Commissioner in ascertaining when, where and by whom depredations have been committed upon the public lands, and to report to him the facts in each case.

If, upon an examination of the reports so obtained, the Commissioner finds that the facts elicited in any case warrant the commencement of legal proceedings to punish the trespassers, or to collect damages for the waste already committed, or both, he will report the same to the Secretary of the Interior, with his opinion thereon, in order that such further proceedings may be had in the premises as the case may require.

The clerks or employees detailed as aforesaid will not be permitted to make any compromise for depredations committed on the public lands. If any propositions are submitted to them with that object, they will be required to report the same to this office, with a full statement of the facts in the case, showing the nature and extent of said depredations, when and by whom committed, the amount and value of the timber when cut, and the value of the land in its present and former condition, all of which, together with the opinion of the Commissioner, will be submitted to the head of the department for further consideration.

If, in any case, the emergencies should seem to require more prompt action than is contemplated in the rules above indicated, in order to arrest the offender, or to secure the Government for the damages suffered, it will be the duty of the clerk or employee detailed to act in the matter to make direct application to the United States District Attorney for the district in which the waste was committed to institute the proper legal proceedings for that purpose. This course, however, must be taken only in cases where the evidence is clear and indisputable.

The foregoing is communicated for your information. You will observe therefrom that you are not hereafter to act as agents for the protection of the public timber, although your co-operation is expected whenever you may be called on to render assistance to officials charged with the duty.

The Fish-Crow.

The fish-crow (*Corvus ossifraga*) is confined almost entirely to the maritime districts of the Southern States, where it abounds at all seasons. This species is gregarious; yet, as flocks of it sail high above the water, they appear to be paired off. These aerial excursions last for hours of a fine morning, after which the whole descend near the surface of the water, and fish for half an hour, when they alight on trees near the shore, and keep up their gabble, pluming themselves for hours. Again repairing to the water, they fish until sunset, and then fly off thirty or forty miles to roost on the loblolly pine, uttering scarcely a single note as they retreat; but on the approach of the day, the woods echo to their matin cries of gratulation; and they promptly return to the sea-shore noisy and happy, and are soon employed over the bays, rivers, wharves, salt-ponds and marshes, searching for any sort of garbage to appease the appetite. They do not scruple to rob other birds of their eggs and young; even watching the departure of the cormorant and white ibis from their nests, which they rob at the first opportunity. In the salt-marshes they catch and eat the small fiddler crab. They pursue with alacrity the smaller gulls and terns, which they compel to disgorge the small fish caught by them within sight of their oppressors. But the fleet wings of the gulls often enable them to escape. They are able to catch fish alive with considerable dexterity; but cannot feed upon the wing, and are obliged to retire to some tree, stake, or sand-bank. They also seek on the backs of cattle for the larvae of the "bot fly," which frequently are generated in their skin. In the winter and spring, they are fond of many kinds of berries,

such as the cassena, (*Ilex cassena*), holly, (*Ilex opaca*), and the tallow-tree, (*Stillingia sebifera*), a South Carolina tree of Chinese origin. As the mulberry ripens, they flock to it, and the fig-trees sometimes require to be guarded from their depredations. They are also fond of pears, and have been seen feeding on at least one species of smilax.

In Florida, Georgia, and the Carolinas, the fish-crow breeds on moderately-sized loblolly pines, (*Pinus taeda*), making its nest about thirty feet from the ground, and towards the extremities of the branches. In New Jersey, where they are frequently killed in the company of the larger crow, they are more careful, and place their nests in the interior of the deepest and most secluded swamps. The nest is smaller and more neatly finished than that of the common crow, and is composed of sticks, moss and grass, neatly finished or lined with fibrous roots. The eggs are from four to six, resembling those of the crow, but are smaller. It probably raises but one brood of young in a year.

The cry of this species, *ha, ha, ha*, is like a faint mimicry of the common crow; at other times, it is more like an interrupted or half-

THE FISH-CROW.

stified expression of pain. During the breeding season, the notes are much varied, and not disagreeable. The flight is strong and protracted, and at times very high. They also move gracefully on the ground, frequently expanding and contracting their wings. They may be approached and shot very easily; and when one is brought to the ground in this manner, its companions sail over it in numbers, and may be readily killed.

A RUSSIAN INVESTIGATION.—A party of Russian mining engineers visited Castlemaine recently, for the purpose of investigating and reporting to parties in Russia. The thing was done in great secrecy. They expressed astonishment at the Town Reef, which employs about two men only, stating that there was, from their experience in the Ural mountains, room for 2,000 or 3,000 men. At other lines they were astonished at the lethargy of the miners leaving such treasures under foot. This party of gentlemen intend to visit, as members of a Russian school of mines, other gold fields, and so far as could be seen, they are reticent as to what they are about.

RICHARD B. CONNOLLY, of the Tammany Ring, has opened negotiations looking to a restoration of a part of his plunder, now held in the name of his son-in-law.

The Salmon Fisheries on the Columbia.

EDITORS PRESS:—I doubt if the extent of the salmon fisheries on the Columbia river, or the magnitude of this suddenly developed interest to our State, is generally understood.

To visit some friends engaged in this business I last week went down the river to Brookfield, W. T., the site of one of our largest canneries, and on this trip learned much of this industry that was a surprise to me. Owing the PRESS a great good will, I will tender for the benefit of its readers, some of my observations.

To make my statements more easily understood by all, I will observe, in the outstart, that much the greater part of the fish taken here are put up in tin cans of one pound weight, and that each establishment manufactures its own cans; hence they are spoken of and known as "canneries." The most approved and quite expensive machinery is employed, with Chinese

ballast, the fisherman, about sunset, moves out into the river and drops his net on a line across the current, by which it is borne down many miles, as is often happens, before the coming morn. The fisherman during the night passes back and forth along the line to release his net from snags and remove to his boat the fish he may find entangled in its meshes. At day light the nets are hauled aboard, and all the boats belonging to each cannery assemble and, with their bowlines attached to a steamer, are towed up to their respective quarters, where they now discharge the catch of the night. The fish, on reaching the cannery, are, by a process of butchery and cooking, which I shall not now attempt to describe, quickly transferred to cans, hermetically sealed, and packed in four dozen can cases, ready for shipment to any part of the globe.

Wheat has been the great staple of Oregon, and the main dependence of her people for revenue, but the salmon fisheries on the Columbia, it is shown, in product, last year, exceeded in value, by far, her entire wheat crop. So large has the demand abroad for Oregon salmon become to be, and so profitable its supply, that not a few of the men engaged in the business found themselves suddenly worth hundreds of thousands. The discovery of this fact has served to so stimulate the business, that the run of 1877 finds the facilities for taking fish in the Columbia nearly, if not quite, double. No less than 1,000 fishing smacks are now on its waters, and the river from the lower cascades to the bar at its mouth, a distance of 150 miles, is said to be a maze of floating nets. The amount of capital required to prosecute this business on the scale attempted this year, is immense, which, to make appear, I will give a few figures kindly furnished by my friend Mr. Truman Tyrel, Superintendent of the Brookfield cannery.

The cost of buildings and machinery was not given, but I think it cannot fall short of \$70,000; 50 fishing-smacks, rigged complete, \$300 each; 50 nets, costing the sum total, boats and nets, \$30,000; steam tug *Edna*, of Brookfield, just built, \$18,000. Then passing over the heavy outlay for plate-tin, packing-cases, salt, etc., we note the wages, at \$1 per day, of 35 Chinamen can-makers, 250 Chinamen, employed in the packing-house, at \$2.50 per day; also 100 white laborers employed, including fishermen.

The above relates to but one establishment of the 29 on the river, a carefully prepared statement of the working capacity of each of which I will now give.

The capacity of each cannery is measured by the number of cases they are prepared to pack this season, if the fish can be taken. It must be remembered a case, as here given, comprises 48 one-pound cans:

Proprietors and locations.	Capacity, in cases.
F. M. Warren & Co., Cascades.....	20,000
Jackson, Myers & Co., Rainier.....	30,000
Quinn & Co., Quins.....	15,000
John West, Westport.....	30,000
Watson & Bannan, Manhattan.....	25,000
J. W. & V. Cook, Clinton.....	50,000
Hepburn & Co., Woody Island.....	15,000
Watson & Co., Tongue Point.....	20,000
Bradly, Davis & Co., Upper Astoria.....	25,000
Anglo-American Packing Co., Upper Astoria.....	30,000
J. A. Hawthorn & Co., Upper Astoria.....	25,000
Fisherman's Packing Company, Upper Astoria.....	20,000
Bradoll & Co., Upper Astoria.....	35,000
A. Booth & Co., Upper Astoria.....	50,000
John A. Delsin & Co., Astoria.....	30,000
Geo. W. Hume, Astoria.....	25,000
Sternberger & Co., Astoria.....	20,000
Kinney & Co., Astoria.....	50,000
T. M. Warren & Co., Brown'sport.....	20,000

WASHINGTON SIDE.	
Wm. Hume, Eagle Cliff.....	20,000
Cutting & Co., Eagle Cliff.....	35,000
Joseph Hume, Eagle Cliff.....	50,000
Hapgood & Co., Waterford.....	25,000
Warren & Co., Cathlamet.....	30,000
Leuridge & Prindle, Bay View.....	30,000
Columbia River Salmon Company, Glen Ella.....	20,000
Fitzpatrick, Davis & Co., Fisherton.....	30,000
J. G. Megler & Co., Brookfield.....	50,000
Pillar Rock Packing Company, Pillar Rock.....	20,000

Total, in cases..... 1,135,000

Should the catch of salmon this year enable all of these establishments to run to the full limit of their capacity, as above given, 1,135,000 cases, or 54,480,000 cans, of fish will be the product, aside from barreled fish, which are put up in considerable quantity. These canned goods, at \$6 per case (the price generally obtained last year), will represent \$6,810,000 in gold coin, quite a clever sum for an infant industry, and a handsome fruitage for our beautiful Columbia. It is estimated that an average fish will fill 16 cans; hence, to meet this year's lay-out of these canneries, 378,333 salmon will be required, and the pay to the fishermen, for catching them, will be \$189,166. The fishing season is now fairly in, and will probably continue till about the 15th of August.

I want to say, in conclusion, to your readers, that for many facts in this brief of our piscatorial bonanza up here, they are indebted to Mr. Truman Tyrel, of Brookfield, a gentleman every way trustworthy, and to him and his talented lady, the writer is under obligations for the cordial hospitality of their pleasant home during his sojourn in that place.

N. W. GARRETSON.
Albany, Oregon, May 1st, 1877.

GENERALS Sheridan and Crook are fitting out a small expedition to start from Green river, on the Union Pacific, and march north through Camp Brown and around the Big Horn river to the Yellowstone. After locating two military stations north of the Big Horn country, for which Congress has appropriated \$200,000, the expedition will return by steamer down the Yellowstone and Missouri rivers.

Continued from page 378.

erations that are going on in different directions very quietly, to test the value of old claims by a small mill operation, and then to open claims for more permanent business. These are the efforts that help keep up and encourage every true interest.

The Gwin Mine.—Near the Mokelumne river, the dividing line from Amador county, and about five miles from Jackson, and three miles from Mokelumne hill, is considered the great high chief of Calaveras county mines. Common report says that recently a single blast exposed \$100,000 worth of specimen gold quartz. But I have been there recently, and Wm. M. Gwin, Jr. made no blow of any such occurrence, and though very hospitable, seemed less inclined to talk of rock than the topics of the day. His venerable father, Senator Gwin, carried out a few samples of pay ledge rock that glittered with streaks and spots of the pure metal, and yet we were told that the sulphureted part was really richer than that showing the metallic gold. A little sample of 30 ounces, sent as a present to San Francisco, was pounded up, and yielded \$66.66, making a yield of over \$70,000 per ton. That must have been over average rock, of course. The mine is worked to 1300-foot level. Drifts run off from shaft there, north and south. In north drift, about 90 feet from shaft, struck the rich ore, and have run about 90 feet in the ledge of good ore, giving six stopes to run upon to the 1200-foot level.

The hoisting and pumping machinery are very complete, and 60 stamps are run by water power. When running to full capacity they hoist and crush daily 120 tons. Now they are only running a small force and 28 stamps. The huge timbers for the mine are now hauled about 20 miles, but will soon be floated down the river to the mouth of the canyon, one mile below the mill, and thereby save very much cost. The desulphurizing works below the mill are of the first class roasting and chloridizing. The ample and luxurious mansion has upper and lower verandas, all hanging as it were on the steep hillside, which by terraces, walls and steps is made very elegant, and highly adorned with the choicest trees and flowers. One cannot blame the venerable Senator for choosing this as his summer retreat from city life. Whoever views the situation and all the difficulties of building up such an extensive and very expensive enterprise, must admire the courage and ability of Wm. M. Gwin, Jr., planner and director of the entire business from the beginning. The outlook from this mine is at present very favorable for an immediate future of successful working. I could give many interesting facts, but the parties seem averse to too much publicity of even the simple facts, for fear they may be construed as "blow," or publicity sought by them. But if they continue such retortings as I witnessed, the facts will out, and all will rejoice and say, "We knew old Calaveras had a branch of the true Mother lode, if not the entire trunk."

Calaveras county, June 9th, 1877.

BELL'S MINE.—We understand there are many who read the account of Bell's very rich strike, made near Auburn about two weeks ago, that are inclined to discredit the story. It is a matter of little difference whether anybody else believes it or not, so long as those most interested know and realize the happy fact. Rich rock had been taken out from the surface down, but the main strike was made on Monday, two weeks ago. From that time until the Wednesday evening following, there was taken out, as near as we can learn, between \$20,000 and \$30,000. The last three pans taken out that day contained nearly, or about \$10,000, and he was that evening offered \$20,000 for the mine, provided he would take out no more. He accepted the offer and quit at once; tore away his hoisting apparatus and put a man on the ground to watch the claim until the bargain was consummated. The party who made the offer did so in the interest of others, which others have not come to time, and the trade has fallen through. Bell is perfectly indifferent as to whether he sells or whether he don't. He left plenty of gold in sight and, as he says, while there may be only ten or fifteen thousand left that is easily obtainable, there may be a hundred thousand, or even more. He commenced on Thursday to get things in readiness for working again, expecting to start in next Monday, and we will soon know whether the mine contains much or little gold. —*Placer Herald.*

FIRING WITH PETROLEUM.—Experiments have recently been successfully made in Italy on a method of burning petroleum under steam boilers, which consists simply in pouring the oil over a thin layer of asbestos. The petroleum burns with intense heat, while the asbestos, being incombustible, is not affected, but serves as a means of retaining the oil and acting as a wick. During the experiments sheets of paper placed beneath the furnace were not injured, although the heat from the oil above was most intense.

CUTTING CAST IRON TUBES OF LARGE CALIBER.—An apparatus for this purpose, invented by Reishauer and Bluntschli, of Zurich, is described in the *Schweizerisches Gewerbeblatt* for 1876, p. 130. It is constructed of three cutting wheels, resting in stirrups which are pressed upon the tube by a connecting vice-screw. A cutting iron, between two of the cutting wheels, is pressed against the tube by a second screw, and the whole apparatus is turned around the tube by hand.

USEFUL INFORMATION.

Hints to Flour Millers.

We recently gave some notes on balancing buhrs from a practical miller. Our flour mill-reading readers will be interested in reading what John M. Truax, a prominent and practical New England miller, in a recent communication to the *Millstone* has to say upon the subject of fast and slow grinding:

To my mind, the reasons given for fast or slow grinding have not been shown. The quantity to be ground must depend upon the texture or density of the stone, the draft, the number and depth of furrows, and the grinding without heating. No more grinding should be done than can be done without heating. The heating is the stopping spot. The quantity that every mill ought to grind is that quantity that can be ground and not heat, whether it is five, 10, or 20 bushels per hour. If every miller will observe this as his guide, he will do the best work that he is able to do.

In speaking of heating, I mean to say that the grain should not be so heated by pressure or rubbing, as will start the juice or essential oils of the grain. If the grain oil is started by friction, that friction produces heat, and that heat dries and evaporates the grain juice, and the virtue of the flour is impaired. Any amount of cooling will not repair the damage done by heating. The steam that rises from the hot running mill is the vapor from out of the essential oils of the grain, and is lost in the bread. To recommend the grinding of 10, 15, or 25 bushels of wheat per hour is bad advice, imprudent. Millers differ in the selection of stones, and differ about their dress, and the motion of their mill. One will have one kind and way, and another another kind and way; but whatever way they select, when they go to grinding, their quantity per hour should be that which they can grind and not heat, whether it is three, five, 10, or 20 bushels per hour. Do not impair the substance for the bulk per hour. Blood heat is as high as can be warranted without impairing the product. It may be an ambition to grind fast, but an old adage is "haste makes waste." If millers are ambitious, let that ambition be applied to the making of a perfect running mill. Select the very best buhrs, and put in a thoroughly common sense dress; a dress that will granulate the whole kernel as nearly as possible. Keep the stones as far apart as possible, and keep the texture or grain of the stones clean. Let this be the miller's ambition. But stop adding to quantity when the mill is at blood heat, and as much less heat as they are able to, and let the bread makers and eaters have in the flour all the virtue that Mother Earth has produced.

WOOD PRESERVED BY INJECTING TANNATE OF IRON.—We read in the *Journal of the Franklin Institute* that M. Boris recommends Hatzfeld's process, which is based on an ingenious idea. The tannate of the protoxide of iron, which is soluble, absorbs oxygen rapidly from the air, and is transformed into insoluble tannate of peroxide. The operation is two-fold: first, injection of tannic acid; second, injection of a protoxide of iron. For this purpose pyrolignite is used, which combines the advantage of cheapness with that of not injuring the woody fibers. The injection is made in close vessels, with the same apparatus as for creosote. The inventor claims the following advantages: first, the complete insolubility of the tannate of peroxide, seems to give a complete guarantee of durability; second, the injection is so made as to yield a great excess of tannic acid, which, being free, coagulates the albumen of the wood, tanning it, so to speak, and transforming all woods into a kind of oak, very rich in tannic acid.

OBLIGATION TO STOP TRAIN TO PREVENT ACCIDENT.—In the case of Morgan against the Pennsylvania Railroad Company, the Pennsylvania Supreme Court held: "A failure to stop a train, when a child is seen on the track in front thereof, is not necessarily and in all cases negligence on the part of the railway employees. Where a child, on the track in front of an approaching train, evidently saw its danger in time to escape, and attempted to run off the track: Held, that the engineer had a right to presume that it would succeed, and to run his train accordingly. Held, further, that where the child, in such case, was prevented from escaping by an unavoidable accident, occurring too late for the engineer to stop his train, the railroad company was not responsible for running over it."

MAKING CRACKED WHEAT.—*Millstone* replies to a query as follows: "Cracked wheat is usually made on small buhrs, portable mills, of sharp porous French buhr stone, being best adapted for the purpose. The mills most generally used will crack about 10 to 15 bushels per hour, and the cracked wheat is then passed through a reel, or series of reels, covered with different numbers of wire to grade it. The apparatus required, of the capacity referred to, will cost about \$400, including the mill; or it can be furnished of a less capacity for less price."

Success with Mineral Oils.

Inasmuch as our State has begun to develop its resources of mineral lubricating oils, it is well to examine their value as compared with the organic oils largely in use. At the late meeting of the Railway Master Mechanics' Association, there was rendered a report of a committee appointed to examine into and report on the subject of lubricants. They recommended a good quality of natural earth oils as the best to use for lubricating machinery and journal boxes. It was less expensive and of a better quality than other oils. When treated so as to reach 28° of gravity it was found to work with perfect success, even on so sandy a road as the Lake Shore. It had been reported on favorably from Canada in the North to Kentucky in the South. A test of various oils had been made with the oil-tester on the Lake Shore road; sperm, lard and tallow were used, and none of them found to possess qualities which render their use advisable. In their experiments the committee used a machine the size of a regular axle-box, and 50 drops were poured in at a temperature of 60°, and the wheel was allowed to revolve at a rate of speed equaling 35 miles per hour until a temperature of 200° was reached. The length of time, number of revolutions and amount of friction were all noted and placed in the form of a table. He called their attention to the result obtained from tests with paraffine, which costs from 25 to 30 cents per gallon, and which has been used on the railroads in preference to lard oil. Paraffine costing 25 cents, with which six experiments had been made, showed 24 minutes required to reach the maximum temperature, during which time it gave 11,685 revolutions; castor oil, costing \$1.25, which required 28 minutes to reach the temperature allowed, gave 12,946 revolutions; manufactured oils A, B and C, costing 35 cents, 90 cents and 25 cents respectively, required 19½ minutes, giving from 9,285 to 9,653 revolutions; sperm and tallow required only 17 minutes to reach 200° temperature, with less than 8,000 revolutions.

FLY PAPER.—The hot weather last week brought us flies by thousands, if not more. We meet them thus, getting the hint from an exchange: "Powdered black pepper is mixed with syrup to a thick paste, which is spread by means of a broad brush upon coarse blotting paper. Common brown syrup will answer, but syrup made from sugar is preferable, as it dries quicker. For use, a piece of this paper is laid upon a plate and dampened with water. The paper may also be made directly at the mill by adding sugar to the pulp, and afterwards one-quarter to one-third of powdered black pepper, and rapidly working it into a porous absorbent paper."

GOOD HEALTH.

Sugar as Food.

The action of sugar upon the system has long been a matter of controversy. With this, as with most other things we eat, much good or evil depends upon the times and quantities, etc., of the partaking. The ruinous effect of sugar upon the teeth has long been an orthodox belief among parents. *Hall's Journal of Health* takes occasion to renew the whole subject and we quote a few paragraphs:

Harm has been done by propagating the notion that sugar is injurious to the teeth, by diverting attention from real causes of destruction or decay. The eating of any amount of pure sugar cannot injure the teeth directly, because it has no residue, it is wholly dissolved and passes into the stomach.

But let it be remembered that the practice of eating sugars or candies or any other sweet-meats largely, will inevitably cause a disorder of the stomach and generate gases there, which will speedily undermine the health of the teeth.

By insisting too much on the fact that sugars and candies destroy the teeth, an impression will grow that if these are mainly avoided, the person so doing will have good teeth, and this leads the mind away from the necessity of keeping the mouth clean and the stomach healthful. If these things are well done, and the teeth are kept plugged in a finished style, teeth naturally or hereditarily "poor," may be kept in a good state of preservation for many years.

All forms of dyspepsia have a direct tendency to destroy the teeth. Whatever causes acidity of the stomach is ruinous to the teeth. A tablespoonful of the purest syrup of loaf-sugar, taken three times a day before meals, will destroy the tone of the healthiest stomach in a very short time. And when it is remembered how many patent medicines are made up in the form of syrups and sweet lozenges, and how common the use of them has become, it need not be wondered at that every second or third person met on the street knows the meaning of "sour stomach" or dyspepsia.

So far from sugars and pure candies injuring the teeth or the health, they would, if used wisely and in moderation, as sole desserts, be actual preventatives of both; especially if alternated, as desserts, with fruits and berries in their natural, raw, ripe, fresh, perfect state, by banishing from our tables the pestiferous pie, the leaden pudding, and pastries and cakes of every name, which, as desserts, always tempt to excesses which lay the foundation for dis-

eases which torture for a lifetime, or bring speedily to the grave.

Let the spirit of this article be distinctly understood. Pure sugars and candies do not injure the teeth, except indirectly, by their injudicious use in exciting acidity of stomach or dyspepsia, as will any other kind of food, or drink, or beverage, if extravagantly used.

At seasons of the year when fruits and berries may not be had, ripe, fresh, and perfect, as desserts, pure sugars and candies may be used as such in their stead to great advantage, because they are healthful, being warming, nutritious, and agreeable; hence, as a table article, they are very valuable, while the almost universal love of them shows that they were intended to be eaten. If a child is not allowed to eat anything containing sugar it will sicken and die in a very short time. Children need the carbon, the fuel contained in sugar to keep them warm; without it they would perish from cold; hence the love of sweet things is an instinct, implanted by the kind and wise Maker of us all for the child's preservation.

The Effect of Tobacco on the Human System.

In the fourth annual report of the Michigan State Board of Health, Dr. Scott relates something new in the influence of tobacco on the human system, as follows: "There has come under my notice for several years, but more particularly during the last two years, a kind of rheumatic condition of the walls of the chest. The patient complains of a dull, heavy pain in the chest walls. The disease in a large majority of cases is confined to the left side. The pain is circumscribed and limited to a space of not more than two inches in diameter, just below and a little to the left of the left nipple. At times the pain is very severe and always constant day and night, when the patient is awake. I have investigated the disease to some extent, and find it to be more common among tobacco users, especially those who use the weed to excess. Patients suffering from this complaint invariably come to their physician with the belief that they have heart trouble. I have not found signs of organic lesion in any of the cases that I have examined, but there does exist in some of them what might be called 'irritable heart.' I am convinced that the greater number of the cases are the result of intemperance, either in the use of tobacco or other stimulants, for the reason that when the patient abstains from the use of them for a short time, his pain ceases and his condition improves. In one case, where the patient abstained from the use of tobacco for 13 months, the pain entirely ceased; but at the end of this period the gentleman recommenced the use of tobacco, and after three weeks' use the old pain returned with all its severity. I am certain that quite a number in this vicinity are receiving treatment for heart disease, when if they would reform in tobacco using they would speedily recover."

SLEEPING ROOMS.—The air which passes out of the lungs is wholly innoxious. If re-breathed without any admixture of other air, it would induce instant suffocation. It contains a large amount of carbonic acid gas. This gas is condensed by cold, and falls to the floor; heat carries it to the ceiling; hence the practical fact, that in warm weather those who sleep on the floor breathe the purest air; while in very cold weather the higher one sleeps above the floor, the better is the atmosphere. Hence, in a warm room, sleep as near the floor as possible; in a cold room, the higher the bed is, the better. A striking illustration of one branch of the statement is found in Dr. Hall's new book on "Sleep." When the jail-fever was raging in England, it was the custom to hand the food and water to the prisoners through a hole in the floor above them. A case is mentioned where the jailer and his wife died in one night in consequence of the effluvia of the prisoners' cell below; while the prisoners themselves continued to live, showing conclusively the concentrated malignity of the air at the ceiling, as compared with that on the floor. The same principle has an illustration in the narration in the same pages, of the terrible incidents in connection with the "Black Hole of Calcutta," where it was speedily noticed that relief was given by sitting down on the floor. From these statements, it is clear that it is better to have a fire in the fireplace in a close room in winter than to have no fire; and for two philosophical reasons—the fire rarefies the carbonic acid gas, and compels it to seek the ceiling; besides, it creates a draft up the chimney, thus causing cold air to come in more copiously.

DON'T RUN AFTER A MEAL.—We do not mean that a man should not exercise due haste in pursuit of a meal, but he should be calm after he has caught it. A gentleman and his son the other morning were a little late for their customary town train on the South Western, and had "to make a run for it." They were successful in their attempt, and caught the train. But the younger gentleman gasped for breath, made a few motions with his hand, and would have fallen if he had not been caught. Before the train arrived at the next station he was dead. The verdict of the coroner's jury, following the opinion of the medical witness, was to the effect: "That death arose from syncope of the heart, brought on by running, after a hearty meal." Such was the end of a gentleman only 30 years of age.

Four insertions are rated in a month.
Subscription in ADVANCE—Postage paid—one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by registered letters or P. O. orders at our risk.

SAMPLE COPIES.—Occasionally we send extra copies of this paper to those we believe would be benefited by subscribing for it themselves, or who are willing to hand the paper and speak of its merits to others. We call the attention of such to our prospectus and terms of subscription.

WRITE for the MINING AND SCIENTIFIC PRESS. We invite not only professional men, but practical miners and mechanics to contribute to our columns. All communications will be kindly treated. Authors, as well as readers, will be benefited by corresponding.

ADDRESS all letters to the firm, and not to individual members, or others, who may at any time be absent.

Our latest forms go to press on Thursday evening.

SAN FRANCISCO:

Saturday Morning, June 16, 1877.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Pavement of Sluices; Holding Door Knob Screws; Typographical Transmitter for Automatic Telegraphs, 377. The Week; California Mines; Our Patent Department; The Mechanics' Institute; Nevada County Reunion, 384. Pacific Coast Coinage, 385. Patents and Inventions; Notices of Recent Patents, 388. Free Reading Room in Oakland; Items of Interest from the Mines, 389.

ILLUSTRATIONS.—Device for Holding Door Knob Screws; Sluice Used in Hydraulic Gold Mining; Black Pavement for Sluices, 377. Grass Valley, Nevada County, Cal., and Surrounding Country in the Year 1853, 385. The Fish Crow, 382.

CORRESPONDENCE.—Birds-eye View of Sierra County Mines, 38. Calaveras County Mines, 378-39.

MECHANICAL PROGRESS.—The New German Patent Law; Rolling Hoop Iron; New File; Steel Hawser; How to Galvanize Iron; A New Swiss Boring Tool; A Novelty in Railway Construction; Steel Grain Cars, 379.

SCIENTIFIC PROGRESS.—Durability of Aluminum; Velocity of Light; Mound Builders; Source of Electricity in Living Bodies; Point of Fusion; Resurrection of Liniment; Curious Phenomenon with Palladium; Sun Spot Cycles; Marine Sounding-Line; Spectrum of Electric Light; Progress in England, 379.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments, Meetings and Dividends; Review of the Stock Market for the Week, 380.

MINING SUMMARY from the various counties in California, Nevada, and Arizona, 381-83.

USEFUL INFORMATION.—Hints to Flour Millers; Wood Preserved by Injecting Tannate of Iron; Obligation to Stop Train to Prevent Accidents; Making Cracked Wheat; Success with Mineral Oils; Fly Paper, 383.

GOOD HEALTH.—Sugar as Food; The Effect of Tobacco on the Human System; Sleeping Rooms; Don't Run After a Head, 383.

MISCELLANEOUS.—Cutting Uncle Sam's Timber; The Fish Crow; A Russian Investigation; The Salmon Fisheries on the Columbia, 382. Bell's Mill; Firing with Petroleum; Cutting Cast Iron Tubes of Large Caliber, 383.

The Week.

The feature of the week past has been the extremely warm weather, which has lasted so much longer than our usual hot spells at this time of year. Its principal effect on the mining interests is that it will materially lessen the quantity of water in the ditches to the gravel mines, and, by rapidly melting the remaining snow, shorten the already brief water season. The weather has been the hottest ever experienced in California. The whole State has had a broil. The hottest coal was at Soledad, where Fahrenheit was 120°. Through the interior there were varying heats, from 106° to 113°. In the city the highest point was 99°; but this comparatively moderate heat is greater than we have had in June for the last five years. The most notable fact of the heating was its long duration. Instead of yielding at the end of a three-days' lease of power, the burning sun clung to us for full five days; but now the spell is past and the city breathes again. The warmth seems to have had the effect of a hot-house on mining stocks, for they have started ahead at a lively rate. Everything shows an advance over prices which have prevailed so long, and now the brokers are happy. News from the mines continues favorable from nearly all quarters, as a glance at our Mining Summary will show.

THE Carson mint coined \$301,220 in May, of which \$30,000 was in trade dollars.

California Mines.

At the anniversary of the Pacific Stock Exchange last week, considerable champagne was drank and a good many speeches made. Most of the remarks made were of a congratulatory nature over the success of the enterprise and the business done. One member who had been talking about the price of stocks, and expressing an opinion that they had gone low enough, said: "What we go by is the Comstock. There is nothing outside of that that amounts to a row of pins for speculation or anything else. There is merit in it. There is a chance of striking something there. It has been the place of the greatest mines in the world."

No one doubts in the least that the Comstock is the place of the richest mines in the world, for its bullion product is the best proof of that; nor does any one doubt that there is a chance of striking something almost anywhere there. This will be conceded by all; but the statement "that there is nothing outside of that that amounts to a row of pins for speculation or anything else" is pretty sweeping. Of course the gentleman making the remark didn't know much about the subject, taking his ideas of mining entirely from Stock Board Associations, but it shows the general feeling among that class of persons who mine entirely with certificates of stock. Without in the slightest degree desiring to detract from the merits of the Comstock as a mining center, which no one familiar with it could do, we still object to such remarks as the above being passed around in the press of the coast without comment. There are hundreds of places where people have invested their money in mining operations which amount to a good deal for legitimate mining purposes. True, these places do not amount to much to the brokers, for there is little speculation with them; but for square, honest mining, many may be ahead even of the Comstock. The remark quoted would lead any one not familiar with the subject to believe that there was nothing going on in mining except on the Comstock, and that that was the only place looked at by capitalists.

This is far from being the case. California, particularly, is in a prosperous condition as to its mining interests, very few of its mines being known to brokers, while for some time the Comstock and other Nevada mines, the favorites of the brokers, have been in a very much depressed condition. This state of affairs is probably due to the brokers as much as to the mines, in both cases, and though not complimentary to them, a moral might be pointed out if necessary. To show that there is some activity outside the Comstock, and leaving aside the other States and Territories entirely as not necessary to prove the position, a hasty glance over the mining news of this week from California alone will convince any one. The following items, of the many that might be quoted, the details of which are in our "Mining Summary," will be sufficient.

The Hinckley mine, Amador county, from the old 40-foot shaft of which \$18,000 was taken out, is to be started up again in search of more rich pockets. The Potosi, in the same county, is about to be started up, as is the Wildman. A feature this year in mining is that carried on in the river beds, where the low stage of the water admits of operations which have not been carried on of late years. We notice that in one place on the South Fork of the Feather river, a man named Price has struck a rich spot and is taking out gold at the rate of \$500 to the man. The old French lead, near Rich Gulch Flat, Calaveras Co., has been sold to a company who are going to put up a water power mill upon it. A good many abandoned mines are being re-opened throughout the country. A nugget weighing one and three-quarter pounds was found in one of these claims near Mokelumne Hill last week. An important development has been made on "the ridge" in Nevada county, between the Middle and South Yuba rivers. The tunnel run by S. B. Hunt, proves that the old river channel traverses this ridge under the lava formation, and that from Snow Point to Bloomfield, a distance of nine miles, it lies as yet untouched. This leaves a vast amount of rich new mining ground in that county yet to be worked, and which has been heretofore unknown. The Yuba River mine, which consists of a drift under the river so as to get at the rich gravel in a new way, has struck dirt which is pretty rich, besides proving the project to be practicable. The drift seems to be low enough down, and no water has interfered. The ultimate success of this enterprise will have the effect of inducing others also to try this system of mining. The twenty-stamp mill of the Republic mine, Eureka township, Nevada Co., will be at work in a month. Rich rock has been struck in the Providence mine in the same county, at least 500 feet south of any yet worked in the mine. A rich ledge was struck last week on Emigrant hill, above Elizabethtown, Plumas Co. In the same county a new company has been formed to sink a shaft in the old channel which crosses the bed of Jamison creek. A shaft 140 feet deep was sunk there once before, but when they struck the washed boulders the water drove them out. This time, the company is composed of working miners, who have a good pump and will set at work in earnest. The lava beds at Oroville, Butte Co., which are worked entirely by Chinamen, are said to be yielding in the aggregate \$10,000 per week.

Our Patent Department.

As illustrative of the estimation in which the MINING AND SCIENTIFIC PRESS Patent Agency is held, and of the success attendant on properly directed efforts to obtain patents, we call the attention of our readers to the fact that of the seventeen patents granted last week to Pacific coast inventors, fifteen were obtained through our patent department. We give elsewhere in this issue an abbreviated description of these patents, which are of varied character. Our patent department has now been in operation so long that its conductors are thoroughly conversant with all the intricacies of patent business, and the patronage extended to it is sufficient guarantee of the estimation in which it is held by Pacific coast inventors. This position has been obtained by attention to the interests of clients, promptness in transaction of business, energy in "pushing" applications, skill in drawing up specifications, knowledge of the details of the patent office work, and upright dealings.

This department is organized in the best possible manner for quickness in obtaining patents, as active and reliable agents in Washington are employed to give personal attention to cases which are prepared here; and when necessary telegraphic instructions may be sent. The experience gained by many years' labor in this particular field has resulted in an accurate knowledge of mechanical details and familiarity with inventions of every class. As for a number of years by far the greater number of Pacific coast patents have been obtained through our agency, the managers are naturally well acquainted with what has been done here, and understand perfectly the requirements of Pacific coast inventors.

The Mechanics' Institute.

The annual meeting of the Mechanics' Institute was held on Saturday evening last. President Hallidie in his annual report stated that the alterations made in the building have involved considerable outlay, but have likewise largely increased the revenue from rentals, and provided room for valuable books. The very great value of the works of reference, among them being many sets of books which it would be impossible to replace, and which have taken years to complete and place on the shelves, has compelled the Trustees to recognize the fact that like all valuable property liable to removal, they must be carefully protected against careless handling, thoughtless abuse, and possible theft. Some of the most valuable books, despite the rules and precautions against removal, have been carried off and not returned. In every respect the accommodations for the requirements of the Society are inadequate, and for some time past the Trustees and members have felt the necessity of a more capacious building, containing rooms of sufficient dimensions for the library, the reading-rooms, lecture hall, class-rooms, museum, etc.

The report also discusses generally the depressed condition of business from the labor standpoint, and opposes Chinese immigration. The aim of the manufacturer is not so much to employ human beings for the sake of the number employed, as to employ those who in the individual capacity tend to the greater happiness of society and to the moral and intellectual advancement of the people.

We need some such man among us as Sir Titus Salt, of Saltaire, England, who died quite recently, and who by his patient perseverance, indomitable energy and true benevolence, built up a new industry and established in employment and homes a community possessing many of the best elements of promise and progress. For the benefit of San Francisco, if any of our capitalists are disposed to emulate the noble example of Sir Titus, a biographical sketch of the Yorkshire manufacturer is incorporated in the report. Salt, with proper discrimination, gave away hundreds of thousands of pounds in benefactions; he founded the alpaca manufacture in England; employed thousands of work people; built the considerable town that is named after him; remained autocrat of its control until his death; endowed it with baths, library, lecture halls, etc., and departed this life leaving a fortune of some millions sterling, all of which had been honorably amassed by industry.

During the past year there have been added to the library 2,310 volumes, as per the following classification: Science and art, 396; fiction, 1,080; general literature and essays, 174; biography, 74; history, 103; poetry and drama, 33; travel, 92; law and political economy, 12; theology and religion, 1; encyclopedias and dictionaries, 54; philosophy, 3; sundries, 9; bound newspapers, 46, and donations, 258. The total number of volumes on the shelves at this time is 29,516. During the year 799 ordinary members and 4 life members have joined the Institute. The financial condition shows a balance in favor of the society, of \$158,936.

The present revenue from rents is \$875 per month, and from membership dues \$862.10 per month; total, \$1,737.10. The current disbursements, including cost of alterations, are \$1,558.10 per month.

After the meeting the new board of directors organized as follows:—President, A. S. Hallidie; Vice President, P. B. Cornwall; Secretary, James Duffy; Treasurer, H. L. Davis; Corresponding Secretary, Ernest L. Ransome.

Nevada County Reunion.

Nevada county residents and ex-residents turned out in large numbers, on Saturday of last week, to celebrate their annual reunion. The gathering took place at Badger's Park, in Oakland. In the absence of Hon. Robert Watt, President, Hon. E. G. Waite, one of the Executive Committee, presided over the exercises, which were of the most interesting and enjoyable character. About one thousand persons were present, and the number would have been larger had it not been for the extreme heat which prevailed during that and several preceding days.

The literary exercises, which took place in the pavilion, were opened by a poem, written for the occasion by Mrs. Nellie Chapman, of Virginia City, formerly from Nevada county, and read by the author. This was followed by another poem, written by Mrs. E. K. Waters, but read by Miss Nellie Holbrook. Both poems were of a high literary character, eminently appropriate to the occasion, and were well read and received. The elocutionary effort of Miss Holbrook received much applause.

The oration of the occasion was pronounced by Hon. John Barber, in which he briefly reviewed the pioneer history of Nevada county, and paid an eloquent tribute to the worth and heroic death of the lamented Meredith. Blum's band was in attendance, and discoursed most excellent music. Dancing preceded the literary exercises for about an hour, but the extreme heat which prevailed prevented a very large participation in that portion of the exercises.

The company adjourned from the pavilion about one o'clock—the most of them to take lunch, *a la picnic*, in the grove, where tables were placed for the convenience of those who brought their own luncheon. A number of tables were also spread upon a platform near the center of the grove, to which invited guests and speakers were invited, and to which others had access who chose to purchase tickets at the low figure of 50 cents—thus making them practically open to all. When the speaking commenced, the canvas which had previously surrounded the tables was thrown down, and all were admitted to hear the speaking.

The tables were presided over by Judge A. C. Niles, who announced the regular toasts as follows:

First regular toast—"The Gravel Banks of Nevada"—they never repudiated legitimate drafts." This sentiment was most appropriately responded to by Hon. Wm. H. Sears, of San Francisco.

Second—"The Bar of Nevada County." Hon. Senator Sargent was called upon to respond. The Senator's remarks were fitting and appropriate. He paid a merited tribute to the uprightness, the learning and the eloquence of the bar of Nevada county. Among other incidents and facts presented was the statement illustrative of the intelligence, learning, and persevering energy of early Nevadans; that he once stood upon the floor of the Senate Chamber in Washington, and saw no less than five persons who were then members of that body who had formerly been residents of Nevada county.

Third—"Our Educational Institutions." This toast was responded to by Professor Martin Kellogg, of the State University at Berkeley, in his usual happy and effective manner.

Fourth—"The Ladies of Nevada County."—The audience missed the rich and racy speech which ought to have been heard in response to this toast by the necessary absence of A. B. Dibble, Esq., of Grass Valley, who was expected to reply, but was compelled to retire from the ground at an early hour.

Fifth—"The Pioneer Press of Nevada County." was responded to by W. B. Ewer, of the SCIENTIFIC PRESS of San Francisco, who started the first newspaper ever published in Nevada county. Numerous incidents connected with the establishment and continuance of the pioneer press of the county were rehearsed and listened to with much apparent interest by the many present, who well recollected the scenes and occurrences referred to, and which took place from twenty to twenty-five years ago—a long time back in the history of a California city.

The re-union throughout was a most pleasant and enjoyable affair, and will doubtless lead to a still more general attendance of future gatherings of old Nevadans. We understand that it is the intention to collect and publish in book form, a full report of the proceedings of this gathering, as well as the one held last year, in Nevada. Such publications will be of much historical interest and importance to the future historian who will some day write a history of California.

A "Great Register"

Was opened and received the signatures of a large number of old Nevadans, whose autographs it is proposed to thus hand down to posterity with record of date of arrival in the county, and address at time of signature.

The Executive Committee which had the re-union in charge, comprised Robert Watt, Chairman; Chas. C. Leavitt, Secretary; George D. Dornin, E. G. Waite and John M. Days.

The following gentlemen were elected as officers of the society for the ensuing year: President, Hon. John Garber; Vice President, Hon. A. C. Niles; Secretary and Treasurer, C. C.

GRASS VALLEY, NEVADA COUNTY, CAL. AND SURROUNDING COUNTRY IN THE YEAR 1853

Leavitt; Executive Committee, H. W. Sears, A. D. Dibble, H. H. Pearson, W. P. Maguire and A. W. Potter.

Our Illustration
Is from an original wood engraving prepared in this city from a drawing taken of Grass Valley as it appeared in the fall of 1853. Old residents will readily recall to mind many of the buildings shown, and recognize the general correctness of the view of the town as it appeared at that time, in the second or third year of its existence. The construction and appearance of the buildings furnishes a very correct idea of the architecture and general mode of building towns in those pioneer days of California life. The Congregational church and the Methodist Church South, are the only buildings shown in the engraving which our recollection can call to mind as now standing. This engraving has been carefully preserved by the writer and is the only relic left of the *Telegraph*, the pioneer paper of Grass Valley, the materials of which were destroyed by fire in the summer of 1862.
A similar engraving was also prepared about the same time of Nevada City, but the block has been lost. A print from each of these engravings was neatly framed and exhibited at the pavilion during the day by Mr. C. Voy. The pictures attracted much attention from those who were familiar with the two places a quarter of a century ago.

Pacific Coast Coinage.

Probably as good an indication of the result of mining operations on this coast, for the past year, as could possibly be shown, is the report of the United States branch mint in this city. During the fiscal year ending June 30th, 1877, (the mint now being closed for annual repairs), the amount coined was \$46,101,500, or \$10,112,000 in excess of last year, when the work was considered extraordinary. There were 28,529,000 pieces of different denominations coined, as follows:

GOLD.		
DENOMINATION.		VALUE.
Double eagles.....		\$32,400,000
Eagles.....		66,000
Half eagles.....		32,500
Quarter eagles.....		5,000
Total gold.....		\$32,552,500
SILVER.		
Trade dollars.....		\$3,042,000
Half dollars.....		2,825,000
Quarter dollars.....		2,270,000
Dimes.....		412,000
Total silver.....		\$13,549,000
Grand total.....		\$46,101,500

This statement shows the largest coinage of any mint in the world during the same space of time. Since the organization of the branch mint at San Francisco, in 1854, the total output has been \$430,532,553 gold, and \$26,049,712 silver, or a grand total of \$456,582,265. This is indeed a most remarkable showing, and must stand unparalleled in the history of coining operations. The three mints of the United States, in order to meet the demands upon them for subsidiary coins to displace paper fractions, have been run to their utmost capacity, and this has resulted in the extraordinary coinage as shown in the case of the San Francisco mint.

The following table will show the relative coinage of gold and silver at this mint for the past few years, and shows, also, that although the silver coinage has increased materially, the great bulk is still in gold, although the popular impression is to the contrary:

	GOLD.	SILVER.	TOTALS.
1876-7.....	\$32,552,500	\$13,549,000	\$46,101,500
1875-6.....	27,036,500	8,053,000	35,089,500
1874-5.....	26,200,000	4,327,000	30,527,000
1873-4.....	22,302,500	2,550,500	24,853,000
1872-3.....	16,907,000	94,500	17,001,500

These figures alone are sufficient argument in favor of mining as a business, and show, moreover, that although that interest is temporarily depressed at present, it has added wonderfully to the finances of the country during the past year. An interest that can produce in hard coin upwards of forty-six millions of dollars in a year is not to be put aside because a few men have made bad speculations in stock gambling. It must be recollected, moreover, that this is not all; as the Carson mint product is not counted here, nor is the bullion shipped east and coined there.

The San Francisco mint is now the most complete in the world. Many very great improvements have been added of late, and the capacity increased. The coin is now made better than ever before. The old process of passing the ingots through the rolling mills from nine to thirteen times in order to reduce them to the proper thickness for the die punch, caused such a hardening of the metal that they had to be annealed twice so as to soften them. Mr. Cicott now passes them under a diminished pressure from fourteen to eighteen times without annealing, and the strips are in better condition than those annealed and pressed by the former process. This has had the effect of lessening the labor in the annealing room, as there are less canisters used, and the coiner introduced a larger canister, which holds an entire melt, which is subjected to a slow fire for forty-five minutes. By these and other improvements Mr. Cicott, it is claimed, has been enabled to increase the capacity of the mint from thirty to forty per cent., and this, too, in the face of a greatly reduced appropriation.

FOR SALE OR LEASE.

Corey & Kingery Mine for Sale or Lease. This mine is a gold bearing quartz lead, situated on French Creek Siskiyou county, Cal., 7 miles south of Etna. Mine opened by tunnel and shaft 170 feet below surface; average width of lode, 18 inches. For further particulars call and examine our mine, or address us at Etna, Siskiyou county, California.
 H. C. COREY,
 D. B. KINGERY.

ARITHMETIC MADE EASY.

ROPP'S EASY CALCULATOR

Is a new publication that must prove of incalculable benefit to Farmers, Mechanics and Business Men. It is so rapid and original as to startle the most scholarly, and yet so simple and practical that the most illiterate in figures can instantaneously become his own accountant. It enables thousands to accomplish in a minute what they could not learn to calculate in many months. The first part contains an entirely new system of tables, which show at a glance the exact value of all kinds of Grain, Stock, Hay, Coal, Lumber, Merchandise, etc., from one pound up to a car load, and for any price that the market is likely to reach; the interest on any sum for any time at 6, 7, 8 and 10 per cent.; correct measurement of all kinds of Lumber, Saw Logs, Cisterns, Tanks, Granaries, Bins, Wagon Beds, Corn Cribbs; a Time, Wages and many other valuable tables. The second part is a practical arithmetic, and embodies a simple mechanical principle which enables any one familiar with the fundamental rules to become a lightning calculator; and by which over two-thirds of the figures and labor required by the ordinary methods, and fractions with their intricacies, are entirely avoided. The work is nicely printed on fine tinted paper, is well and elegantly bound in pocket-book shape and is accompanied by a Silicate Slate, Memorandum and Pocket for papers. It is by far the most complete, comprehensive and convenient pocket manual ever published.

Price, bound in Fine English Cloth, \$1.00.

Sent direct from the Eastern publisher, postpaid, on receipt of price, by P. O. order, registered letter, or receipted by express. Address

Steam Engines & Boilers.

NEW AND SECOND-HAND.

One Patent Straw-Burning, Portable Engine, (new,) fire box boiler, the best Portable Engine on the coast; built by Ransom, Sims & Head, Ipswich, England.

One Steam Fire Engine, second-hand, in excellent condition, with 200 feet leather hose, very cheap, just the thing for a small town. Button & Blake, builders, Waterford, N. Y.

One second-hand Stationary Engine, 14x30 inches, link motion, with or without hoist gear.

One second-hand Stationary Engine, 8x20 inch, with or without hoist gear.

One Upright Boiler, Horizontal Engine on wheels, Eastern make, 7x12.

One Upright Boiler, Horizontal Engine, San Francisco make, 6x12.

One small Stationary Engine, 3½x7 inch.
 One Steam Boiler, 40 inches diameter, 16 feet long.

One 8x10 Straw-Burning Portable Engine.

One Traction Engine, three wheels, rubber tires, double cylinder, 6x10 inch; Thompson's patent, D. D. Williamson, builder, New Jersey.

One Stationary Engine, 10x20, just had a thorough repair, almost as good as new.

One Stationary Engine, new, 12x24, independent cut-off.

One 6x12 Engine and Boiler, can be mounted if required. Very cheap.

Various other second-hand Engines and Boilers for sale cheap.

J. W. RILEY,

P. O. Box 2361.

San Francisco.

Buy the Best.

Before purchasing an American Watch, examine the different styles manufactured by the NEW YORK WATCH COMPANY, at Springfield, Mass. They are the latest and best improved manufacture. You can depend upon them for fine finish, durability and perfect time. They are sold at favorable prices—in fact, no higher than many of the inferior styles. Examine into the merits of this Watch before you buy any other. Our word for it, you will not regret it.

DEWEY & JORDAN, Agents,
 433 Montgomery St., S. F.

SUTTER CREEK, February 26th, 1875.

Messrs. DEWEY & Co.—I have received my Letters Patent through your agency. And, for your promptness accept my thanks. Yours,
 S. N. KNIGHT.

Superior Pianos for the People at Popular Cash Prices.

More than TEN THOUSAND prosperous families on this Coast need Ten Thousand GOLDEN PIANOS to make TEN THOUSAND HOMES MORE PLEASANT AND ATTRACTIVE.

Prices of good Pianos have long been too high. Our people could not afford to buy them. But many will find it not only pleasant but profitable to purchase

The Brilliant and Durable GOLDEN PIANO

Which we now offer the readers of this paper

At Greatly Reduced Popular Cash Prices.

We Guarantee them to be as represented, of superior tone, finish and durability.

Samples can be seen by calling at this office. We keep no expensive sales-rooms and attendants.

We shall sell none but superior and desirable instruments, but give our customers the benefit of prices far below any before offered on this side of the Continent.

Prices of the Golden Piano:

	The Installment Plan Prices.	Our Reduced Cash Price.
The Golden Piano, \$500	\$350	
(UPRIGHT—C.)		
The Golden Piano, \$375	\$300	
(SQUARE—No. 1.)		
The Golden Piano, \$500	\$350	
(SQUARE—No. 2.)		
The Golden Piano, \$600	\$400	
(SQUARE—No. 3.)		
The Golden Piano, \$800	\$450	
(SQUARE—No. 4.)		

We invite our readers who wish to look at Pianos for themselves or friends, for immediate or future purchase, to call and examine our samples.

Those who cannot call will be supplied with further descriptions and recommendations by sending to this office.

Metallurgy and Ores.

TULLOCH'S AUTOMATIC ORE FEEDER,

Awarded the Centennial Medal.

The TULLOCH AUTOMATIC ORE FEEDERS have been practically tested during the last year and a half in 40 mills, of from five to 80 stamps each, and have, in every case, given perfect satisfaction. The Tulloch machine is so constructed that the drop of the stamp feeds the ore in just such quantities as the stamps require. Each drop regulates the supply required for the next drop, whether it be more or less, and this is the true principle of an automatic feeder. The tray moves longitudinally, and a stationary scraper forces the material forward at each backward movement of the tray, thus insuring the perfect feeding of all classes of ore, whether it be dry or wet.

We append a few extracts from the many testimonials which we have received from mill men and practical mining men, of the effectiveness and positive action of the Tulloch Feeder. We do not depend solely upon these testimonials, as we are aware that testimonials are easily secured for almost any machine, but the high character of the parties certifying to those herewith given, will establish their value and genuineness.

Mr. Jos. G. Fair has 28 in use; says: I regard them superior to any Feeder with which I am acquainted; I consider no mill perfect without them. Mr. E. R. Burke, Sumner mine, Kern county, has 16; They never get tired; no man living can feed a battery as well; they save us in labor alone \$48 a day. Mr. Green, of the Phoenix mill (12), Amador, writes: The first machine we had is working away; is as good as ever; have not spent a dime on it; in use 14 months; you need fear no competition on wet ores. Mr. W. H. Armstrong, of Consolidated Virginia mill; We are running 60 stamps with your Feeders; they give unbounded satisfaction; they have not cost the company one dollar since starting up. Mr. H. C. Bidwell, Supt. Green Mountain and Gold Stripe companies, Plumas county, writes: From the start they have done splendidly; no trouble whatever; requiring but little attention; a boy can manage them; the saving in both labor and castings is fully one-half over the old style of feeding by hand. Mr. Preston writes: I have four of your Automatic Self Feeders, and my mill men each and all say they are the best they have ever used. They are an improvement on all I have ever seen, being simple in construction, and good for either wet or dry crushing; refer to over 40 mills using them; they are guaranteed to give perfect satisfaction. Send for circulars.

F. OGDEN, 413 California Street, S. F.

PATENTED

CAST STEEL SHOES AND DIES.

Guaranteed Cheaper than the Best Iron.

IMPORTANT NOTICE.

Reduction in Price from 16 Cents
to 12 Cents Per Pound.

Owing to our largely increased business, the present low price of iron from which our Steel is manufactured, and the improved facilities for casting and forging, we take great pleasure in announcing that from and after this date we will supply our IMPROVED CAST AND FORGED STEEL SHOES AND DIES FOR QUARTZ MILLS at twelve cents per pound, delivered at San Francisco or Sacramento, instead of sixteen cents, as heretofore.

We also furnish Steel Plates for Blake and other Ore Crushers, Steel Gut Gearing, etc., for Mills and Hoisting Works, Steel Pan Shoes, Battery Cams and Tappets, etc., etc.

Address all orders, with dimensions or drawings, to

GOLD, SILVER AND COPPER MINING.

Address, FRASER, CHALMERS & CO., Chicago, Ill.

Hoisting Engines, Diamond Pointed R. C. Drills. Manufactured by M. C. BULLOCK.

Continued from page 381.

from \$50 to \$5,000 per ton in silver. The ledge, which is situated near the Eagle mine, is called the Vandewater, and is owned by L. F. Dunn, L. A. Moore and V. Smith. A shaft has been sunk on it to the depth of 20 feet, at which depth the vein carries four feet of ore that assays on an average \$75 per ton. The course of the vein is nearly due north and south, and some of the ore shown resembles that produced by the Moonlight, which worked \$400 per ton. We are informed that old miners pronounce the Vandewater ore of the best prospects for a good mine ever discovered in the county.

OSCEOLA DISTRICT.

THE NEW CAMP.—Pioche Record, June 9: On Sunday evening Dr. S. L. Lee and Jim Mattson returned here. After their return an account was given of that camp, and what was doing. Dr. Lee showed some specimens of coarse gold that he had washed from three panfuls of dirt—the gold amounting to about one dollar—and also some specimens of gold quartz taken from the Golden Eagle ledge, owned by Jim Mattson. The ardor of most of our prospectors was considerably dampened when told that all the claims to the placer diggings had been located. Preparations are being made to receive the mill which is to run on Golden Eagle ore. The water to run the mill will be brought a distance of about five miles, from some small lakes on Jeff Davis peak, which are accessible, and there will be no difficulty in getting the water to Osceola. A small dam has been built, and a good one, but there is no necessity of running wild over it.

WHITE PINE DISTRICT.

THE JENNIE A.—White Pine News, June 9: Superintendent Ford, accompanied by Messrs. Kendall and Williams, of San Francisco, arrived here the fore part of the week, and have since been engaged in examining the Jennie A. mine. These gentlemen seem to be well pleased with the prospects of their property, and they have reason to be, for we learn the mine looks splendid. By late assays it has been discovered that the ore carries \$10 to \$15 per ton in gold. This, we believe, is the first instance in which gold has been found in the ores of this section.

Arizona.

MINERAL PARK.—Arizona Enterprise, June 6: The Mineral Park mill was closed down after a most successful run of about five months, and must have "panned out" during that time not less than \$50,000. I have no means of estimating the average working value of the rock consumed during the run, but have it from good authority that rock has been worked which went as high as \$2,380 per ton. This is the highest pulp value of any ore worked in the mill since it has been running. I believe that one or two lots of ore have been worked that brought the owners in debt to the company, but that was before it was generally known that it took rock worth at least \$100 per ton to pay the millage and percentage. Since then we have not heard of assays giving less than \$105 per ton, and I have no doubt that the average assays of ore worked during the last five months has reached \$300. The greatest quantity of ore from any one mine was about 300 tons, taken out of the Lone Star. The balance was in lots of from one to twenty tons, and it is likely that 25 or more mines were represented. We feel quite confident that the mill will be started again soon. In the meantime work is being done, and ore taken out on many a claim, and prospecting is developing new mines all the time.

HACKBERRY.—From Hackberry reports come in very favorably in the shape of silver bullion; five large bars came in last Sunday morning. Only about 10 days before that, as much arrived, and was shipped to San Francisco. Material is being provided for the new mill, and before many weeks the machinery will be in place and at work.

PIMA.—The people of the southern part of the Territory expect much from the results to be achieved by the Pima company, and are anxiously waiting developments. This is in the Pima range. It is 10 feet wide and has been developed to a depth of about 100 feet.

In Arivaca district, upon the McCafferty lode, several locations have been developed to a depth of 30 or 50 feet. This ledge and some 13 other locations in the same vicinity will supply ore for the Sierra Colorado mill, which is soon to be erected upon the Arivaca ranch. The miners in the vicinity are anxiously awaiting the arrival of this mill, and have a lot of ore which will run up from \$200 up into the thousands, awaiting reduction.

REPORTS bordering upon the marvelous come to us from the Aztec district, which is newly discovered, and is in the neighborhood of the Santa Rita. Some wonderfully rich ore has been found and the surface indications are said to be excellent.

The Santa Rita placers, the most extensive in the Territory, are still being worked. Something over 400 men are at work there, and some of them are doing very well. The great trouble with this, as with all other placer mines in Arizona, is the scarcity of water.

In Maynard district, work is still being prosecuted upon the Bean mine, and the tunnel is being pushed in rapidly by two shifts. We understand that the controlling interest in this mine has recently been sold to parties in San Francisco.

The Silver Glance mining company have been very successful with their operations at Montezuma. They went into possession of the mine about a year ago, and since that time have made 21 miles of road, and built their smelter, which has since operated very successfully. It is a 30-inch water jacket with a Baker blower, and is of 12 tons capacity. There is a Corliss engine, and it is a first-class outfit. They have also a small reverberatory furnace, used for reducing ferris to copper matte. The mine has been developed by means of a tunnel, which is now in 130 feet, and the mine has been opened by crosscuts and drifts on the surface about 3,000 feet. About 50 tons of bullion and copper matte have been made. The bullion is high grade.

Work is still going on upon the McCracken, which is now down to a depth of 525 feet. The ore-dumps are full, and there is ore enough out to supply the new 20-stamp mill.

In this county the Tip-Top, in Humburg district, makes a fine showing. Some of the ore taken out at a depth of 90 feet is marvelous—solid chunks of horn silver.

PECK DISTRICT.—Things are coming to look bright once more in the Peck district. There are some 30 men employed in the Peck mine, and tons of very rich ore are being taken out from the mine daily.

In Turkey Creek district, Hamilton & Co. are sinking on the Trinity, and taking out very rich rock.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

MINEBATH BELLE S. M. Co.—June 8th. Location: Look-out District, Inyo county. Directors—Wm. F. Cashman, Jas. B. Peck, J. H. Jacobs, Robt. Sheehy and Chas. M. Blair.

KING M. & SMELTING Co.—June 8th. Location: Nevada. Capital stock, \$10,000,000. Directors—John O. Earl, F. L. Weaver, A. R. Baldwin, Joseph Tyson and N. C. Fasset.

ALTA PETROLEUM Co.—June 11th. Object: To work and manufacture asphaltum, coal tar and all products of asphaltum and petroleum. Directors—C. E. Convis, T. E. Atkinson, Giles H. Gray, J. D. Hooker, Dorville Libbey, S. N. Putnam and Henry Kimball. Capital stock, \$500,000.

PAULADES G. & S. M. Co.—June 10th. Location: Nevada. Capital stock, \$1,000,000. Directors—T. J. Bell, T. B. Ludlum, J. J. Dunne, W. P. Willard and E. W. Sawyer.

PAULADES G. & S. M. Co.—June 13th. Location: Ward district, Nevada. Capital stock, \$700,000. Directors—T. J. Bell, T. B. Ludlum, J. J. Dunne, W. P. Willard and E. W. Sawyer.

EDWIN M. Co.—June 13th. Location: Butte county, Cal. Capital stock, \$2,500,000. Trustees—J. W. Wesson, Geo. McDonald, C. M. Claves, A. B. Paul and T. E. Wingard.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

ROTARY PLOW OR CULTIVATOR.—William Freeborn, San Francisco. This invention relates to an improved cultivator or rotary plow for digging and turning the soil, and it consists of a series of concave-convex flanges or mold boards, arranged spirally around a horizontal shaft in such a manner that when the shaft is rotated the mold-board will cut and turn the soil in furrow slices. The curve and overhang of the spiral are so arranged that while rotating the soil will be turned in the same manner as by an ordinary plow. Successive furrows of the same length are cut diagonally across a strip of ground in width equal to the length of the hub of the rotating mold-boards. This rotary plow can be mounted in any suitably constructed frame and can be operated by animal, steam or other power. The advantages gained by the use of this plow as claimed by the inventor are as follows: 1. Economy; as a much greater surface of ground can be plowed over in the same time with the same expenditure of power, than by the present mode. 2. Better work; this manner of plowing avoids sole friction and leaves the ground under the furrow in the same condition as it was previously. 3. Equal twisting and cracking of furrow slice and as complete inversion of the same as by the present mode. 4. The whole field can be plowed without leaving head lands in any part of it. 5. This plow can be operated more economically by steam than any other, as the motion of the revolving mold-boards is in the line of direction; consequently the lightest engine consistent with requisite steam capacity can be used. 6. In consequence of the compact form of this plow when operated by steam, harrowing and seeding can be done at the same time as the plowing.

OIL AND FILTER CUP.—Andrew J. Stevens, Sacramento. This invention relates to a novel construction for oil cups, such as are employed to supply lubricating material to machinery, and it consists in the employment of a double cup, in which the lubricant is first filtered and purified, and secondly passed to a receptacle, from whence by suitable adjustment it is allowed to flow in the necessary quantities to the part to be lubricated.

OYSTER KNIFE.—T. W. Temple, Los Angeles. The patent covers an improved implement for opening oyster shells, after they have been split or serrated by a splitting machine invented by the same patentee. It consists of a handle in which are secured two blades, one of which is fixed and the other adjustable. The implement is simple and easily handled and is quite effective as an oyster opener.

STUD FASTENING.—M. Zacharias, S. F. This improved fastening is intended more especially to fasten into minute holes in the shirt front, such as have heretofore been used in connection with a spiral fastening. This fastening is very simple and effective, as it can be inserted and fastened without trouble and without rumpling the shirt front.

WASHING MACHINE.—Daniel Best, Auburn, Oregon. The improvement in this washing machine consists in combining an endless rubbing belt with two or more pressing rollers which are arranged above the belt. This machine will wash articles of all sizes from the smallest pieces of lace to the largest blankets.

BELTING ROPE.—Hermann Royer, S. F. The object of this invention is to provide an improved article of belting rope, which shall be free from the fault of stretching too much or being too stiff to move freely around small pulleys, and a liability to crack and break off by use. Round rope, of various kinds, is largely employed for the purpose of driving groove pulleys, and it is very difficult to obtain an article which will work well and be durable. When these ropes are made of leather, which has undergone the ordinary process of chemical tanning, they are inferior in tensile strength from the effects of the tanning. When made of pure rawhide these ropes are too stiff to run well on small pulleys; they will stretch too much, and from their stiffness, will eventually cut and break, and wear out. This invention consists in making ropes of fulled or mechanically prepared rawhide, and it is done by first preparing the hide mechanically, by a method previously patented by the same inventor, or by any other means for rendering rawhide pliable without tanning or other chemical process. After the hide is made pliable it is cut around in long threads and these threads are cemented together and wound upon spools or bobbins, and twisted or plaited into rope. The rope made of this prepared rawhide possesses all the strength of the original hard rawhide, and it has the elasticity necessary for belts without the tendency to stretch. It is unaffected by time or atmospheric changes. The advantages are its pliancy and elasticity without the fault of continuous stretching, its greater adhesion to the groove pulleys, and the ease with which splices can be made without making unsightly enlargements at the point of junction.

FRUIT DRIER.—Russell B. Blowers, Woodland, Yolo county. This patent covers certain improvements on a former invention of the patentee. In the previous patent he claimed a heating chamber surrounded by drying rooms with doors and a draft chimney to produce a laterally and downward moving current of air for the purpose of drying fruit and other substances. The present improvements consist in the employment of reversible air currents and a mechanism by which this is accomplished, and also in a means for admitting large quantities of air and bringing them into contact with the heaters so that it will all be heated before passing into the chambers. In order to dry economically by artificial means, it is necessary that any apparatus built for the purpose should be able to dispose of large quantities of the material to be dried in a short time; and as the capacity of air for carrying off moisture is limited, it is necessary to pass it through the apparatus rapidly and in large volumes without the use of expensive blowers or other machinery for producing a draft. This is accomplished by Mr. Blowers by means of the draft chimney and passages described in the previous patent, and he has found that with certain additions the apparatus may be made useful in drying lumber, fish, hops, chicory and various other substances.

COMPRESSED COFFEE.—Frank Silver, S. F. This invention differs from other preparations in which a combination of coffee and sugar is used in this: that the inventor does not employ the sugar for the purpose of utilizing its sweet principle; but he puts it through a preparatory treatment which destroys the sweet principle and imparts to it a quality very nearly resembling coffee both in color and taste. Ground coffee soon loses its flavor, and as it is very inconvenient in many cases for persons to roast and grind coffee, as fast only as it is required for use, any process which will supply the market with a coffee fit for immediate use, and one which will not lose its flavor or deteriorate with age, will be of value, especially to travelers and persons living at a distance from market. Ground coffee can be easily preserved by being consolidated into blocks or cakes, if a suitable ingredient is employed to cement or conglomerate the grains together, and at the same time not affect the decoction after it is prepared for drinking. Melted sugar has been used for this purpose, but the deliquescent quality of such sugar caused the blocks or cakes to liquify and melt down. This invention overcomes this difficulty, by making the preparation of burnt sugar and coffee mixed in a certain manner and compressed in cakes or blocks.

CUBE SUGAR MACHINE.—Francis Westerman and Otto Mursch, S. F. The object of this invention is to provide an improvement in that class of apparatus which is designed for the conversion of granular sugar into solid cubes for market, and it consists in the employment of molds which have a reciprocating motion, alternately beneath a hopper containing the loose sugar, and beneath a series of stationary punches. At the end of each movement these molds are forced upwards, first into a mass of sugar, which has been cut off from the filled hopper by a slide, so that the molds are filled, and then beneath the stationary punches, which thus extract the sugar from the molds and leave it upon a surface for removal. These operations are carried out by means of suitable cams and levers. These molds can be easily removed bodily for cleaning and others substituted without delaying the work and the molds are easily washed ready for replacement, thus avoiding one of the most troublesome features of cylindrical or other shaped machines where the

molds are stationary and the punches movable; or where springs are used, as all the parts become speedily gummed up and rendered useless unless they can be easily cleaned without stopping the operation for any great length of time.

ORE ROASTING FURNACE.—H. G. Livermore, S. F. The improvements in this patent are especially useful in connection with furnaces which are intended to extract quicksilver from its ores. It consists in the employment of a secondary or supplemental fire, which heats the ore from below the floor over which it passes, and in the employment of the waste heat from the furnaces for drying the moisture out of the pulverized ore which is spread in thin layers upon pans over the condensers and furnace. A blast of hot air may also be introduced above the body of ore in the furnace at some point between the feed and discharge openings so as to assist in roasting the ore more effectually. As the construction of Mr. Livermore's furnace necessitates the pulverizing or breaking of all the ore into small pieces, it will only be necessary to provide machinery for this purpose; but most of the cinnabar mines produce from one-half to two-thirds and often more of the ore in this fine condition, so that the expense will be comparatively small, and the inventor is thus enabled to avoid all the expense of mechanical furnaces, or elevating devices for bringing the ore to the furnace, and even the vacuum or blast apparatus, generally necessary, can be dispensed with.

SULKY PLOW.—Frank A. Hill, San Leandro. Mr. Hill's latest improvement in sulky plows consists in mounting the crank axles upon which the bearing wheels of the plow are mounted, in reverse positions, so as to throw one of the wheels in advance of the other for convenience in turning the plow at the end of the furrow. This arrangement also provides a more convenient disposition of the levers by which the crank axles are adjusted. Mr. Hill also provides a novel arrangement for attaching the rear plow to the plow-beam where two plows are to be used, and detaching it therefrom when it is desired to use it as a single plow. These improvements render the sulky plow much more convenient and easily operated.

SCREW THREAD COUNTER.—Chas. C. Coleman, Honolulu, Hawaiian islands. The object of this invention is to provide a ready and convenient means for determining the number of threads or taps, dies, bolts, nuts, and other articles, and it consists of a series of plates riveted together and having their edges serrated to represent the different threads usual to screws. Either of these plates may be turned out from the others and by trying its serrated edge upon the threads of the screw a glance will show whether it is the gauge sought. With this mechanism the necessary counterpart for a bolt or nut is expeditiously determined.

CULTIVATOR.—John Jones, Stony Point, Sonoma Co. This invention relates more particularly to that class of plows or cultivators in which the plows or cultivator teeth are attached to the two diverging timbers of a V-shaped frame, which frame is mounted upon two rear wheels and a front swivel or steering wheel. The improvement consists in a novel combination of levers for enabling the driver to raise and lower the frame and plows without leaving his seat. The arrangement of levers is very simple and convenient, and the power of the driver is applied to the best possible advantage.

SASH LOCK AND FASTENER.—Thomas Stuart, S. F. This improvement consists in constructing a sash lock and fastener with two bolts, one of which serves to lock the two sashes together, while the other locks into suitable notches in the window casing. It also consists in providing bolt sockets in the sashes, which also serve as finger sockets to permit the introduction of the end of the finger for convenience in raising and lowering the sash. This fastener and lock will secure the sashes firmly together and to the casing at whatever position the sashes are moved to, corresponding with the position of the sockets.

AMERICAN MANUFACTURES IN ENGLAND.—The following significant paragraph is from a Birmingham letter in the London Times: "In addition to locks and hardware of various kinds, the Americans are now sending into this district large quantities of machine-made boots and shoes, which find a ready sale, owing to their cheapness and neatness of appearance." The New York Bulletin adds: "It will be the turn next, perhaps, of machine-made ready-made clothing, machine-made hats and caps, etc. There is scarcely any limit to American ingenuity in machine-work, and in times like these it is only ingenuity that can obtain a footing in the European manufacturing markets."

The California mining company, on Monday, paid \$77,914 to the county, and Consolidated Virginia \$14,476, being the bullion tax due for the quarter ending March 31st. The other mines also paid, the total aggregating \$97,921. The Consolidated Virginia shipped, on Monday, \$335,621, and the California, on the new month account, \$208,759, and has in the office \$160,000. The California mill reduced 8,500 tons of ore from the 1450-foot level of the Consolidated Virginia, producing \$629,856; netting \$109.40 per ton.

Free Reading Room in Oakland.

The public spirited people of Oakland have done a thing for the good of the young men which we think could be done in other towns to advantage. They have furnished and equipped a free reading room and it was opened formally on Friday evening of last week. Of the opening, the *Oakland Transcript* says: "Henry Vrooman, President of the Association, very greatly to his regret and that of the audience, was unable to be present. The substitute, Dr. Dio Lewis, unanimously selected as Chairman for the evening, worthily filled his place. Speeches were made by Rev. L. Hamilton, Charles N. Fox, and D. L. Emerson. By far the finest off-hand speech of the evening was made by Daniel Kilpatrick. Although an humble journeyman tailor, he fairly eclipsed the doctor, the lawyer, and the clergyman in his speech. It was witty, fitting, and pertinent to the occasion, and was rapturously applauded."

The Musical Club, at intervals during the evening, discoursed most delicious music. A solo by the wife of Prof. Ogilby, of the State University, was received with tumultuous applause. At the suggestion of Mr. A. T. Dewey, who, by the way, has been the grand moving spirit of this enterprise, blank notices were circulated among the audience, asking subscriptions for the permanent support of the enterprise.

In order that our readers in other parts of the State may know some of the objects of the enterprise we quote from a circular as follows:

The association is designed to promote greater unity of feeling and action in the community for the accomplishment of literary and other good works. It will endeavor to properly maintain a place where the young and the old, the rich and the poor, the representatives of every trade and calling may meet upon terms of social equality; a place to which strangers may come, and in which they can engage their unemployed hours pleasantly to themselves and profitably to each other.

The society differs, in some respects, from all other organizations, and its members hope to increase its strength and wisdom until enabled to introduce new benefits for the patrons of the institution. It will be a constant effort to make the work of the association such as will be an unfading honor to the fair fame of our city, at home and abroad.

In California, more perhaps than in older portions of the country, are needed, especially for the young, places of this character in which the attractions shall be even stronger than the temptations of other places of resort which are often the starting points of a career to ruin. Our aim is to refine and to improve. Our motto is to do as much good as possible with as little harm as possible.

Officers of the Association.

President, Henry Vrooman; First Vice President, W. H. Jordan; Second Vice President, Mrs. J. M. Selfridge; Secretary, J. R. Porter; Treasurer, Mrs. J. I. Spear. [Ex-officio members Board of Directors.]

Directors—L. L. Alexander, Mrs. C. H. Chamberlain, Mrs. C. M. Shepard, Mrs. Jos. McGillivray, Mrs. C. L. Pierson, Mrs. E. J. Grayson, Dr. Dio Lewis, G. W. Armes, A. I. Gladding, David Kilpatrick, A. W. Swett, A. T. Dewey, E. W. Playter.

Items of Interest from the Mines.

We give below items of interest from prominent mines, most of which are collated from letters of the respective Superintendents on file at the offices in this city:

The station at the 1900-foot level of the Ophir is now opened and they will soon commence drifting. Lots of water on the 1700-foot level.

The southeast drift on the 1150-foot level of the Utah has reached the east wall.

They have started drifting west from the upraise of the 1465-foot level of the Mexican.

In the Justice the south lateral drift, 1050-foot level, is found to contain a very fine character of quartz with metal more evenly disseminated throughout; this drift is being pushed ahead with all due diligence.

Chollar ore averages \$24 per ton. The south drift, 1100-foot level of the Overman, is in quartz showing small bunches of good ore.

Eureka (G. V.) cleaned up last week 200 ounces of amalgam.

In the Eureka Con. the ore body on the fifth level is still holding out strong. Have sunk winze in ore body to the depth of 50 feet and still in ore. In drifting on the sixth level cut through a streak of ore, from four to six feet in width, which assays well. Have also come upon ore in seventh level. The furnace is putting out over 10 tons of bullion daily, average assay value \$210.62 per ton; five tons of ore to make one of bullion. Shipment of bullion for the last eight days has been 80 tons. Will soon start up another furnace.

The strong flow of water in the Hale & Norcross continues.

At the C. & C. shaft they have lined the south compartment from the surface to the bottom to receive a downcast of air.

WOODWARD'S GARDENS embraces an Aquarium, Museum, Art Gallery, Conservatories, Tropical Houses, Menagerie, Seal Pond and Skating Rink.

Dine at the Palace Restaurant, 218 Sansome St., S. F.

And in accordance with law and an order of the Board of Directors, made on the thirtieth day of April, 1877, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at the salesroom of J. Middleton & Son, No. 310 Montgomery Street, San Francisco, Cal., on the twenty-fifth day of June, 1877, at the hour of two o'clock, P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

Office, No. 320 California Street, Room No. 5, San Francisco, Cal.

Consolidated Bonanza Gold and Silver Min-

ing Co.—Location of principal place of business, San Francisco, California. Location of works in Eagle and Washoe Valley Mining District, Ormsby county, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the fourth day of June, 1877, an assessment, No. 1, of 10 cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary at the office of the company, No. 19 First Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on Tuesday, the tenth day of July, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the thirty-first day of July, 1877, to pay the delinquent assessment together with costs of advertising and expenses of sale. By order of the Board of Directors.

WM. MARTIN, Secretary.

Office No. 19 First Street, San Francisco, Cal.

THE VICTOR ROCK DRILL.

This machine is so simple in its construction that any person can understand and run it. The DOUBLE GOUGE BIT, patented with this Drill only, is one of its specialties, as it feeds and cleans itself. The machine is a hand Drill and can be operated by two men, who will do the work of ten in the ordinary way. In a word, it is a labor-saving machine which has no parallel, and as such we offer it to the public. For State or Territorial rights, or machines, apply to

HUNT, DOUGLAS & STEWART Process,

Used in Connection With PURVINE

Wooden Amalgamating Pans and Settler.

This is a complete, perfect and economical adaptation of the humid method to the treatment of Gold or Silver ores, associated with

COPPER

And other base metals, or to ores free from base metals. It can be adapted to any first-class Gold or Silver mill, at a reasonable additional expense.

For further information, address

J. O. STEWART,

Georgetown, Colorado.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING and TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

A. J. SEVERANCE & CO.

Office, No. 320 Sansome street, Room 10.

HYATT'S LIFE BALSAM.

As a conqueror of Rheumatism, Gout, Neuralgia, and cure for Scrofula and all diseases arising from impurity of blood, the old and reliable Family Medicine, Hyatt's Life Balsam, stands unequalled, as proven by over 300,000 great cures during the past 30 years. It is a radical vegetable compound of Sarsaparilla, Dock, Guaiacum, etc., and a permanent cure. Sold by all druggists and country grocers. Take nothing else, and if they haven't it we will send by express, boxed, everywhere, at \$1 and \$1.25 per bottle; \$5 and \$6.50 half doz. HYATT & HYATT, 246 Grand street, New York.

Don't trifle with a poor watch when you can buy a good one of Dewey & Jordan, 433 Montgomery street, San Francisco, at prices according to the times.

Machinery.

The Ingersoll Rock Drill

Is Extensively Used in the East and

TAKES THE PLACE OF ALL OTHERS,

Wherever introduced, because it can be run with less power, labor and repairs, and do more work than any other Drill in the market. It has but few parts, is easily handled, being light, and has AUTOMATIC FEED, which saves labor. WE ASK FOR TRIAL AGAINST ANY COMPETITOR. For particular information regarding Drills or Air Compressors, send for circular to

J. B. REYNOLDS,

320 Sansome Street

(Room 10.)

THE O'HARRA CHLORIDIZING FURNACE

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing 20 Tons in 24 Hours by this Process:

One man.....	8 00
One ton.....	3 00
Wood—24 cords at \$3 per cord.....	6 25
Salt—1,600 lbs at 2 1/2 cents.....	40 00

Cost of 20 tons.....	\$52 25
Cost of one ton.....	2 61 1/2

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in Peavine District, Nev., and at the Exchequer mill, Alpine Co., Cal. For further information, apply to

TOLLES IMPROVED CONCENTRATING TABLES.

Improved Concentrating Tables.

The illustration on this page represents an improvement in concentrating tables for ores recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by J. U. Tolles, of Virginia City, Nevada, who has been using the apparatus very successfully in several places. In the engraving, *A* represents a flat inclined table provided with a surfacing of cloth or other suitable material of any kind, and with the ledges *b*, to prevent the material from passing over the ends. *B* represents a peculiarly constructed feed box extending along the upper edge of the table and provided in its front side with a row of discharge openings, *c*, of the form shown, each narrowing down to its lower end and of such a size as the nature of the material requires. *C* represents a receiving box or trough, extending along below the lower edge of the table. *D* represents a leaf or board hinged to the rear side of the trough or box *C*, in such a manner that it may be turned under the edge of the table to conduct the valuable material therefrom into the box, the refuse passing over the edge of the table and discharged upon the ground, or into the box in the rear of the box *C*. *E* represents a rotating tube or pipe suspended lengthwise above the upper edge of the table by endless belts *d*, passing over pulleys *e*, supported in the rigid frame *F*, or by brackets fastened to the frame and extending out the proper distance over the table, the tube resting and rotating upon them as shown in Fig. 2. The tube is provided from end to end with a row of perforations, and with a hand lever, *h*, at one end, and is connected by a hose *i*, to a tank, pump or reservoir, delivering water at a pressure of from eight to 12 feet of head, as the nature of the case requires.

In operating the machine the feed box is narrowed to about one inch at its further end, or has a strip of board set edgewise in the bottom, and running obliquely across the same from the rear to the front side, causing the material to gradually be brought to the front and discharged through the feed holes *c*, upon the table, thereby insuring an even distribution and steady flow of the material to be treated; a steady and copious supply of water is maintained in the box, and the ores, sands or tailings introduced therein. The water escaping through the openings, *c*, flows down in a thin light stream over the face of the table. The mineral particles are deposited upon and retained by cloth or other surfacing material on the face or bed of the table, while the light refuse matter is discharged over the lower edge and discharged outside of the box *C*. After the collection of a suitable amount of metal upon the

table, the supply of water, etc., to the feed box is stopped by the gate and turned upon the other table. Clear water is now supplied to the fine pipe, *E*, and allowed to run down over the table, (for a moment) washing off the remaining refuse sands, and at the proper time the hinged leaf *D*, is drawn (by the rod) under the edge of the table, the pipe being rotated or turned and the water thrown through the perforations upon the table in a row of fine jets, forming an almost continuous sheet or film. By means of the lever *h*, (which should be fastened on the pipe at right angles to the line of perforations), the tube is turned and the sheet of water swept over the table from the top to the bottom so as to drive all adhering particles therefrom and wash them down into the box *C*. After this operation the jets are stopped from the tube, the leaf

thrown back, and the gate shipped to the other feed box, the feed water coming back on the first table, the operation being repeated as often as it is seen the tables are charged with the sulphurets or other valuable metals.

By employing the proper kind of cloth, grooves, riffles, or copper plating, or all of them combined, and giving the tables the proper grade, and properly regulating the flow of water, the inventor finds that he can effect a very rapid and thorough separation without agitating the table, and without power of any kind except the manual labor requisite to change the feed from one table to another, and washing them off by means of the water used in the pipes; he also finds by the employment of the fixed table he can separate particles which cannot be retained in machines which vibrate. By use of the feed openings, *c*, of the form shown, the discharge of the sand, ore or other fine material is rendered very steady and gradual, as it will be carried through the narrower portion of the openings, while the lighter water will pass over the same through the upper large end of the openings, taking up the material very gradually and distributing it very evenly upon the table. It is obvious that the rotating tube may be sustained in any other manner, and that it may be connected in any suitable manner with the source of the water

The object in arranging the perforated pipe so that it can rotate is to permit a gradual change in the direction of the jets, so that their point of impact upon the table can be advanced from its upper to its lower edge, and thereby every portion of the surface subjected in turn to the direct impact of the jets, in order to effectually loosen and drive forward the particles therefrom.

The flow of water can be regulated by the valves operated by the cords. The gate shown in the feed trough, *G*, will throw the water into either feed trough as desired.

The plugs in the ends of the pipes, *E*, are for the purpose of freeing them of any obstructions.

Fig. 3 represents the most convenient form of erecting the tank or reservoir which supplies the tubes with water, it usually being placed directly overhead with water shed underneath.

Mr. Tolles with this apparatus does not profess to do what many others claim to do, but he is running many of them where everything else has failed. He has been running several of these tables on the Comstock for nearly two years and is now building more. By using the proper kind of sizing apparatus in connection with the tables, the inventor is doing some close work with them at a nominal expense of constructing, running and keeping in order. He states that any person using anything of like nature, or any portion of the same for like purposes, without first obtaining license for so doing, will be prosecuted for damages for such use. Persons at a distance can build and run them by first obtaining license and instructions from the inventor, John U. Tolles, at Eureka, Humboldt county, California, or W. S. Tolles, his authorized agent at Virginia, Nevada.

AVERILL MIXED PAINT,

Was awarded the Highest

MEDAL AND DIPLOMA

AT THE CENTENNIAL EXHIBITION FOR A READY MIXED PAINT

THIS CELEBRATED PAINT IS MANUFACTURED BY THE

CALIFORNIA PAINT COMPANY.

THIS PAINT IS MIXED READY FOR USE.

THE PUREST WHITE, AND OF ANY DESIRED SHADE OR COLOR.

It will not peel, crack, nor chalk off, and will last twice as long as the best white lead, prepared in the ordinary way. Is cheaper, handsomer, more durable and elastic than the best of any other paint.

Extract From the REPORT OF THE CENTENNIAL COMMISSIONERS.

"This Paint is quite different from paints in general use. * * * Work which has been done with it, some of it exposed for years to the moist atmosphere of the sea-shore, establishes its great durability. * * * It is mixed ready for use, easily applied, of great beauty, and economical."

Extract From the REPORT OF THE FRENCH (CENTENNIAL) COMMISSION.

"It possesses merits unattainable by the old method of combining paint. * * * It can be applied with great facility and perfect regularity; dries with a rich, glossy surface, and will not chalk or crack off. * * * It never separates, is always ready for use, and will not spoil when exposed to the air. * * * It can be applied by any one whether a practical painter or not."

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being

done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO.,
Patent Solicitors.

SAN FRANCISCO, SATURDAY, JUNE 23, 1877.

VOLUME XXXIV.
Number 25.

Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Science was held on Monday evening last, R. E. C. Stearns in the chair. From J. A. Hosmer a skull and stone mortar were presented. They were found on Anacapa island, at the base of an artificial shell mound, the mound one of a number, and the shells chiefly those of abalone and mussel. Fragments of flint were scattered around, evidently left there by arrow-makers. Fossils of leaves from Blue Tent, Nevada County. Mr. J. R. Scupham, presented two bottled specimens of the *Gordius*, or hair snake, which is not uncommonly found in railway station tanks. One of the specimens, Mr. Scupham said, illustrates the readiness with which a mistaken opinion may be formed on the growth of these filamentous creatures. The two specimens exhibited were placed in a bottle and kept there two or three days, when it was discovered that a long white substance had been developed, apparently a progeny of young *Gordius*. In a little while there was a further increase, and the parties brought the bottle to him for examination. The real history of the animal's development is, that it lays eggs in the water, and these eggs require to be taken up by some insect, such as the cricket or the spider. From the egg they pass into the larva state, and then the insect has to die before the *Gordius* can be developed and come to perfection. The chances are one in 200,000 that all this will not occur, so that 200,000 eggs fail for one that reaches maturity. The creature provides for this by depositing more than this number of eggs. He had examined the specimen with the microscope, and found that in a very small part there is a multitude of ova, probably upwards of 200,000.

Mr. Stearns read a sketch of the life of Col. Ezekiel Jewett, a soldier and scientist, who died at Santa Barbara last May, at the age of 86 years. Deceased served with General Scott in the Canadian campaign of the war of 1812, afterward under the flag of Chile in the revolution from the domination of Spain, and in latter years became a scientist of note and high repute in the field of geology and paleontology. He was also an eager student of conchology.

Mr. S. B. Christy, of the University of California, read some "Notes on the Mt. Diablo Coal Mines." It was valuable as giving an analysis of the various grades of coal in the Mt. Diablo field, and in those of Livermore and Washington Territory. In the Mt. Diablo beds coal is chiefly taken from two veins, the Clarke and the Black Diamond. These lie about 400 feet apart, though sometimes at a greater distance. They are nearly parallel and have a strike northeast and west, with a dip of from 20° to 30° to the north. As usual, they lie between beds of sandstone, which change into bituminous shale as they approach the veins. The roof frequently shows impressions of leaves. Between these larger beds are numerous thin streaks of coal, most of which disappear; but one of them, the so-called middle vein, increases in size to the east until nearly as large as the Clarke vein itself. At the Black Diamond mine the Clarke vein is three feet thick, and at the other mines from two feet to two feet six inches. The Black Diamond vein is eight feet thick, but only four feet are workable, the rest being bone. Difference in brightness, color and luster make it only a matter of eyesight to separate the two coals when mixed on the dump. It is said the Clarke coal takes fire more readily, whilst the other gives more heat. Both crumble readily and are sulphurous. The acid sulphates they contain render the coals unsuited for use in boilers. The ligneous qualities of the deposit were pointed out, and the results of analysis given in connection with specimens from Livermore and the north. The Livermore coal, it was stated, has too much water and ash in its composition to be valuable, while some of the coal north is of fine quality.

THERE is a flurry in New York over the fact that Judge Hilton, head of the house of A. T. Stewart & Co., and proprietor of the Grand Union Hotel at Saratoga, has excluded Joseph Seligman, the well-known banker, from the hotel because he is a Jew.

The Hydraulic Mining Season.

Nearly all the gravel mines will soon be compelled to shut down until the rains come in the fall, and in the meantime the claims will be put in shape for advantageous working when the water is more abundant. Although the water season has been pretty short this year, owing to the scarcity of snow in the mountains, the work done has generally been pretty successful. A good many claims have been compelled to run with less water than they could have used advantageously, but still a general view of the gravel mining field shows a successful season's work, but now the pleasant work of final cleaning up is being done in a good many places, though in others they are still piping away at the banks and utilizing the water as long as possible.

Probably more attention has been called to

Improved Steam Engine Cut-off.

We illustrate herewith a new and simple cut-off, which is positive in its action, has few parts, has no springs or other appliances requiring constant attention and delicate adjustment, and is controlled by the governor so as to cut off steam, we are informed, at from 1-16th to 7-10ths of the stroke. Fig. 1 is a horizontal section through valve chest and cylinder, and Fig. 2 a view of the cut-off mechanism, all of which, it will be noticed, is easily accessible.

The cut-off valve, A, Fig. 1, works on the back of the main slide valve, so that, when either end of the cut-off is down, the steam is shut off from that end of the slide, which moves freely under the cover of the cut-off valve. The shaft of the cut-off valve, it will be observed, is squared in order to admit of the firm attachment of the valve. Where the shaft passes

Fig. 1

Fig. 2

FISH'S VARIABLE CUT-OFF.

the gravel mines of California this year than ever before; and capitalists seem readier to invest in this class of property than they have been heretofore. The depression in stocks in the city no doubt has worked favorably to both the quartz and gravel mining interests of this State. People who have been investing in silver mines have begun to think that perhaps there is something nearer home worthy of their attention in gold mines, and a great many sales of California mines have lately been made. Some of the big gravel mines which have been doing "dead work" for a long time, such as the North Bloomfield, are now in a shape to pay right along and the success of claims of this character does much to draw attention to this sort of mining. There is no prettier work in the world than hydraulic mining when the gravel is good and water and fall plenty; but as the big enterprises need a great deal of money to develop them, poor men cannot always take hold of ground that they are sure will pay. Capitalists have been too shy of this kind of property heretofore, but now they are beginning to have their eyes opened and next year we will no doubt see considerable more money invested in the gravel mines of California.

through the steam chest it fits into a simple bushing, next to which and within the chest there is a collar. The pressure of steam on the chest then forces the shaft outward, making a steam-tight joint between the collar and inside end of the bushing. The use of a stuffing box is thus avoided, and friction is greatly reduced.

Outside the valve chest, and rigidly attached to the rock shaft, is the rock lever, B. In this are guides (dotted lines) for rack bars, C, upon which bars are formed stops, as shown in Fig. 2. D is the governor rod, which, by a short lever, is connected with a pinion which is loose upon the valve rock shaft, and which engages the rack bars, C. It will be evident that any motion communicated to the pinion from the governor will cause the rack bars to advance and recede, and in this way the stops will be moved either nearer together or further apart, in horizontal direction. E is a rod which connects with a bell crank, which is vibrated by an eccentric on the main shaft. This rod moves a sliding bar, F, upon which toes or stops are attached. Inspection of Fig. 2 will show that as this bar reciprocates, the beveled sides of its stops will come in contact with the stops on the rock lever, B. And as one or the other pair of

stops come in contact, the result will be, as the sliding bar continues its motion, that the rock lever will be pushed to the right or left; the valve shaft will thus be vibrated, and consequently the cut-off valve itself will be brought down upon one or the other end of the slide. Now it is clear that the time when this vibration of the cut-off shall occur depends upon the time, sooner or later, when the stops on the sliding bar come in contact with the stops on the rock lever; and if the horizontal distance between the latter is decreased, then this contact will occur sooner, and steam will be cut off earlier in the stroke; while, if it be increased, just the reverse will obtain.

But the distance between the stops on the rock bar depends upon the relative position of the rack bars, C. By slightly converging their guides toward the end of the rock bar, the contact of these stops with those on the sliding bar tends to give the same angular movement to the lever, whether the former are at the outer or inner end of their travel. Then the governor, as already explained, regulates the position of the rack bars, C, and thus controls the action of the device. The inventor points out that the lift of the cut-off valve is very small and need not be more than half the width of the induction port. The outside lap of the cut-off valve is so proportioned in relation to the steam ports in the main slide valve that, when one end of the cut-off valve is down on the back of the main slide, shutting steam off from that end of the cylinder, the pressure on the back of the cut-off valve is equal to the difference of the pressure of the steam in the steam chest and the expanding steam in the cylinder. When the piston has arrived at the end of its stroke the main slide valve has moved back half its stroke, plus the lap and lead, to admit steam to that end of the cylinder; at the same time the main slide has closed the cylinder port at the other end of the cylinder; and its induction port has traveled past the end of the cut-off valve, admitting live steam to the under side of the plate, thus putting the cut-off valve in equilibrium. Consequently the sliding bar, which gives motion to the rock shaft lever, through the toes in the bar and the stops in the lever, has no other resistance to overcome than simply the inertia of the valve, when called upon to move it so as to cut off the steam. The device, we are informed, can be applied cheaply to engines that are now built or running, and requires but slight alteration to existing patterns.

For further particulars address the inventor, Mr. J. Fish, Summit, Union county, N. J.

LADY BRYAN.—The prospects for resuming work at an early day in this famous old mine are now favorable. The new management have made arrangement with the creditors to fund the entire indebtedness, amounting to about \$100,000. This is to be done by issuing bonds to each creditor to the amount of each one's claim. These bonds are to bear interest at the rate of 10 per cent. a year, and a reserve or sinking fund of 25 per cent. of all moneys received from assessments or bullion is to be devoted to paying the interest and redeeming these bonds.

The Treasury Department has issued a circular saying that it will exact from Steamboat Inspectors strict fidelity to the true intent and meaning of the 78th rule and the statute on which it is founded. The duty is enjoined upon Inspectors of frequent visits to excursion steamers in order to have personal knowledge that the equipments are kept up to the original requirements.

A DISPATCH from St. Johns, New Brunswick, received as we go to press, states that a terrible fire is raging at that place. The loss is estimated at between \$10,000,000 and \$15,000,000. Several lives are also reported lost. St. Johns has been peculiarly unfortunate in this respect, having passed through several similar disasters.

JUSTICE WORKMEN.—There are at present 639 men employed at the Justice mine, on the Comstock. This makes the daily expense for labor \$2,556, and for the month of June the pay roll will amount to \$76,680.

CORRESPONDENCE.

The Water Supply of Philadelphia.

R. L. M. Camden, Jr., a California boy who recently graduated in the East, in a letter to his father in this city, gives the following interesting facts concerning the water supply of Philadelphia:

In one of your recent letters you requested me to give you some facts and figures about the works which supply this city with what Paul Danton called "heaven's beverage, pure, cold water;" and in compliance with your request, I have gathered up a few items relating to the works referred to, and now present them to you, and hope they may prove interesting, if not instructive.

Philadelphia is supplied with water by five principal works, all located within the built-up portions of the city. On the east side of the Schuylkill river there are the Fairmount, Spring Garden, Kensington and Roxborough water works, each with a capacity, respectively, of 35,000,000, 43,000,000, 15,000,000 and 13,000,000 gallons in 24 hours; and on the west side of the Schuylkill is the Belmont water works, with a capacity of 18,000,000 gallons in 24 hours. Hence, if each set of pumps were worked up to their full capacity, the city would receive 124,000,000 gallons each day; but the actual amount taken from the reservoirs and distributed through the city is on an average only 41,362,082 gallons per day, or say 15,097,160,069 gallons in a year. The number of gallons actually used in a day or year looks very large, and is, in fact, very large; but it must be remembered that fully a million of people, with all their varied occupations, are the recipients of this water, and that it is spread over 120 square miles of territory.

The water is supplied through about 600 miles of street service mains, and the length of the small pipes which conduct the water from the mains to the stores, houses, factories and other buildings, would reach well on to the Queen City of our Occident. Were all these pipes, large and small, which intersect and interlace the city in every direction, raised from their sunless beds, and hung up over the city, they would resemble the web of some gigantic monster which had been spun out to entrap or menace the puny mortals beneath.

Among a host of other purposes for which water is required and supplied, are 5,363 plugs, 6,000 bath-tubs, 20,000 wash-stands and about 100 public drinking fountains.

The water rents vary from \$3 per year for ordinary dwellings, to \$25 per year for large houses. Factories, and establishments requiring large quantities of water, are supplied at lower rates.

The entire assessment for 1876 amounted to \$1,025,278.50, which was at the rate of about one cent for every 147 gallons. And this, I believe, as low as water can be had in any city in our country.

For many years the Fairmount works possessed greater capacity than any other, but within the last three years the Spring Garden works have had their capacity increased, until they are now able to supply more water than the Fairmount works, and almost as much as the other three works put together.

The Spring Garden works now consist of four large engines, and I was courteously furnished with information concerning them by the engineer, Joshua Bartley, Esq. The engines used at these works have been frequently changed, and were numbered, as put up, thus giving to those now in use the numbers 4, 5, 6 and 7, which have a capacity, respectively, of 5,000,000, 8,000,000, 10,000,000 and 20,000,000 gallons per day. Two of these engines are Cornish, one of which is a side lever, designed by Fred. Graeff, Esq. The steam pressure carried by these engines is 40 and 45 pounds to the square inch.

The Fairmount water works formerly consisted of pumps driven by eight undershot water wheels, but these are now replaced by turbines, and the number of pumps increased. In fact, the old wheels, pumps and building, and the very foundations, have been all swept away by the ruthless hands of innovation and improvement, and the place so altered and changed that I should think even the sweet-faced Naiads would hardly recognize their former home. The place on which the long, low wheel-house stood, is now covered over with flagstones, and near the center is erected a sort of temple, dedicated, for aught I know, to the beautiful nymphs of the fountain.

And here I will say a word about the Centennial water works, though they have, for the most part, passed into the realm of the "have beens." They were situated just outside the exhibition grounds, and consisted of two Worthington duplex engines. They raised, during the exhibition, 383,865,497 gallons to an average height of 200 feet, being on an average of 2,181,053 gallons per day, which ought to have kept the crowd clean and supplied them with ample drink.

The water supplied by the works to the city has been often complained of, and justly so. The analysis of the Schuylkill water which is furnished the city, shows it to contain inorganic materials, 2,763 grains in the gallon; or-

ganic materials, 1.442; total solids, 4.207.

The water of the Delaware river contains inorganic materials, 3.479 grains to the gallon; organic materials, .756; total solids, 4.235.

At high water, the Schuylkill and Delaware both furnish good water, but at low water the former is so contaminated by sewers, the refuse of print works, and other abominations, that the proportions of organic materials is so enormously increased that the water is entirely unfit for drinking purposes. And yet, thirsty thousands have to gulp it down, and with, or by it, too often take in disease, which ends in laying the victims beneath the shades of Laurel hill, close by the fetid waters that sent them there.

And yet Schuylkill water, even at its worst, possesses one redeeming quality. The greater portion of the house service pipes in the city are lead, and if the water was pure, there would be, consequently, frequent cases of lead poisoning. But as the water contains, among other "solids," considerable quantities of the carbonate of lime, the lead pipe, in a very short time, becomes lined with carbonate of lead, which entirely prevents any ill effect arising from the use of the pipes.

Cinnabar Deposits.

EDITORS PRESS:—Having, through your agent, Mr. Joseph Dimmick, become a subscriber to the MINING AND SCIENTIFIC PRESS and also the RURAL PRESS, I feel more entitled to the position of a correspondent than heretofore, and undoubtedly shall use that privilege more or less, from time to time, as occasion might seem to justify. At this time I will say that my motive is to try and obtain some information regarding the cinnabar deposits of the Coast range of mountains and the character and peculiarities of the croppings. I have endeavored to obtain such information from mineralogical works, but the most that I have come in contact with have little or no knowledge of that mineral, being gotten up by parties having no experience in the practical mining or prospecting developments for that mineral. I believe I am safe in saying that if some one of our practical working mineralogists would get up some sort of an essay or treatise on cinnabar, embodying the principal characteristics and peculiarities of the croppings and paying ores of the principal mines in successful operation in this State, giving also a short outline of the quicksilver mines of the Old World, that it would supply a demand that has for several years been felt among prospectors for that mineral in this State. It would not necessitate a very large edition, and could be issued in pamphlet form and sold at a very good profit compared to some of the other works on mineralogy. The greater portion of such works that I have seen endeavor to get too many things in a short space and only give a dim outline of the character of each mineral, and a great many of them are of no practical value to the miner or prospector.

I would further state that I firmly believe that there are rich cinnabar deposits in this section of California; certain peculiarities of rock, differing from any I ever saw elsewhere before, being found here. Most men pronounce it a species of iron, but I have seen a great many specimens of iron ore from different localities and fail to detect the least resemblance to that mineral. I will give you a description of it as it is found on the surface. Color, light brownish-red, with a good deal of orange-yellow intermingled, and seams of clear, transparent, white quartz all through it. When freshly broken it gives off a brown red paint profusely, of a greasy feeling and very glossy when rubbed on the hands. It is of a bright, metallic luster and looks as though it had contained at some time some valuable material, which time and exposure had oxidized or evaporated, leaving a large quantity of worthless trash on the surrounding surface. Were the above croppings to be found anywhere in the gold belt of the Sierras it would have been prospected long since, but situated as it is in this part of California, among farmers and stock raisers, it is almost impossible to form a company to prospect it. It would not take a very large amount of money to test the ground, (say \$1,000,) but I have not the means to spare from my farm to justify me in making the venture on uncertainties. Judging from what little I have heard of the New Almaden mines, I am led to believe that the ground I have described has a very close resemblance to it. I would be much pleased to see in your paper some sketches of the New Almaden and New Idria quicksilver mines, also of other productive mines in this State, describing the croppings, etc., of the two former more particularly, they being among the most prominent.

Potter Valley, Mendocino Co.

Growth of Gold.

EDITORS PRESS:—In a recent issue of the PRESS, I read with much interest an article on the "growth of minerals," and observe that the subject has been discussed in the *Chemical News*, and before the Mineralogical Society of Great Britain. In this connection I would state that I have strong reasons for belief in the growth of gold, founded on my own observation. I am in possession of a specimen of gold-bearing quartz which illustrates, (to my satisfaction at

least), the growth of gold in this sample. Possibly it may be the decay of the cubes and prisms of sulphurets, but nevertheless the aggregation of gold is perceptible and unmistakable. The specimen can be identified by well known gentlemen in your city, among whom I may name Mr. F. Reichling, J. A. Mars, D. M. Hosmer, W. Aug. Knapp and Dr. Henry De Groot. Should your local scientists desire to investigate the subject, I will place the specimen in the custody of Henry G. Hanks, for that purpose.

W. A. SKIDMORE.
Grass Valley, Nevada County, June 11th, 1877.

Gravel Mining.

An Important Development in Nevada Co.

We have, says the Nevada Transcript, during the past four years, written much concerning the section of country known as the "Ridge," located in Nevada county, between the Middle and South Yuba rivers. It consists of a mountainous belt of country intersected by frequent canyons and gorges, and running in a southerly direction from the summit of the Sierra Nevada mountains. On it, from Eureka South to French Corral, mining has been successfully prosecuted, at different points along the line, for the last 20 years. The most important gravel mines of the State are located on that Ridge—among the number are the Milton and Sweetland Creek, the American, Badger Hill, the Eureka Lake company's Consolidated, North Bloomfield, the Blue Banks and others of importance, all of which are on an ancient river channel which traverses the Ridge from Snow Point to French Corral, a distance of somewhere in the neighborhood of 20 miles. The principal mines are surrounded by claims having less development upon them, but the ground is known to be equally as rich as that owned by the larger companies. The developments on the line of the channel have been made at points remote from each other, and where the channel cropped out on the surface and revealed its locality. Intervening between the points worked, a heavy deposit of earth, and in some places lava, is found above the channel, and its course, between such points, has therefore been a subject of conjecture. The theory has for a long time prevailed that the channel which runs from Laporte, Plumas county, via Forest City and other points in Sierra county, is that found on the San Juan ridge, in Nevada county, and that it crosses the Middle Yuba river and enters Nevada county at Snow Point, and follows the Ridge down to French Corral; but just where it runs between Snow Point and North Bloomfield has been a mystery. Between these points the surface of the Ridge is composed of a deep lava formation, which prevents the channel from cropping out at any point, except at Moore's, Orleans, and Woolsey's Flats. These locations are not on the Ridge proper, but are benches several hundred feet lower than the main Ridge.

Some years since, while engaged in mining in the State of Nevada, S. B. Hunt, a former resident of Moore's Flat, conceived the idea that the mines on those flats or benches, had been fed, or rather that the gravel found there was simply an overwash from the main channel under the high Ridge above. He also came to the conclusion that the same amount of money expended in testing his theory there would eventually result more profitably than would the same amount expended in Silver State mining enterprises. He therefore, in 1873, left Nevada and went to San Francisco. After a long time he succeeded in organizing a company, and in 1875 he incorporated. The capital stock was divided into 60,000 shares, of the par value of \$30 each. W. B. Cluff is the President, J. M. Buffington Secretary, and Mr. Hunt Superintendent. After a limited amount of capital was secured, operations were commenced in October, 1875, in sinking a shaft, and the erection of hoisting works, carpenter and blacksmith shops were started at the same time. The point selected on which to sink a shaft, was on a bench close up to the prospected Ridge above. The locality was in a heavy belt of timber, and everything had to be cleared off and roads cut to enable the works to be erected. Practical men who knew the country there, thought the enterprise was a very doubtful one, and that the projector was visionary in the extreme. The encouragement received consisted generally of undisguised sneers—no one believing that the channel run near the point selected. However, Mr. Hunt pushed ahead. The location of the Ridge in the rear of the shaft convinced him that the shaft would eventually strike a heavy body of water, so a tunnel was started in November of last year, and the facts soon warranted the correctness of his conclusions. At 110 feet in depth the eight-inch pump was found unable to cope with the water, and sinking had to be stopped. The tunnel, in order to reach a point beneath the shaft, will have to be run 1,728 feet. Over 200 feet of it had been completed when sinking stopped. By putting on three shifts of men a distance of 815 feet has since been run mostly through a rock that had to be blasted to be taken out. When that point was reached—which occurred on May 26th—the workmen struck through the rim rock into gravel, which there is but little doubt is the main channel, for which the Superintendent has all along been running. As soon as the news spread, the town was wild with excitement. The workmen suspended work, and the event was celebrated in true miner's fashion. The development proves that an old river

channel traverses the Ridge under the lava formation, and that from Snow Point to Bloomfield, a distance of nine miles, it lies untouched in all its native richness. It proves, as Mr. Hunt anticipated, that Orleans and Moore's Flat gravel were only outwashes from the main channel, and their richness indicates what the main channel contains. The tunnel will be pushed ahead until it reaches a point under the perpendicular shaft, which will be about 223 feet below the surface. It is expected the bottom of the channel lies about 170 feet below that, or that the deposit, from the surface to the bottom, is 393 feet. The ground will be drifted out, or that portion of it near the bedrock. Experience has shown that a majority of the gold in the channels in that section is within four feet of the bedrock. The deposit drifted out will be raised to the surface and placed in a dump house, which will hold from 4,000 to 5,000 tons. A sluice will be run through the center, and when the house is filled it will be washed through a sluice 1,000 feet or more in length. It is expected one day's washing will run off all the dirt raised during a week's work and that 500 inches of water will do it. The company own 214 acres of ground, all secured by good title. As soon as well opened it is expected 200 men will be employed in drifting and that they can take out about 600 tons of the gravel per day. It is believed that within the grounds of the company there is the junction of two channels, or that the Woolsey Flat channel is the one struck, and that it unites with the main channel further back in the Ridge. The amount expended by the company in building tunnels, shafts and other outlays, up to date, is but \$30,000. We regard it as the most economical outlay ever made, and from it there will flow greater results than was ever realized from a similar expenditure. It proves that a vast extent of the richest possible mining ground in our county has hitherto been untouched; that there is a field for the profitable investment of millions of dollars; that thousands of men can, in the near future, find remunerative and continuous labor in that territory, and that gold exists there in quantities past computation. The rim-rock of this channel can be traced from North Bloomfield via Snow Tent and Forest City to Laporte, in Plumas county. Hunt's discovery warrants early openings all along the line where work has not before been prosecuted. We feel that too much credit cannot be awarded to the gentleman, who has persevered under all manner of discouraging circumstances, until he has demonstrated to the world what the capabilities of Nevada county are as a field for mining.

Resting Springs District.

A correspondent of the Pioche Record, writing from Resting Springs, San Bernardino county, Cal., says: It is possible that some of the residents of your section may be curious to know what we have and what we are doing away down here on the ragged edge of San Bernardino county. After a residence of eight months in this district, and a thorough familiarity with all its developments and resources, I consider it one of the very largest things on this or any other coast. We have wood and water in abundance, a magnificent climate, inexhaustible beds of peat within six miles, and, as for the mines, I hardly know where to commence or how to say of them. Imagine two or three Eureka and a couple of old-fashioned Pioches condensed into one mining camp, and that camp situated in a wild, new region of country away down on the borders of Death valley, as isolated from the world as were the mutineers of the *Bounty* on Pitcairn's Island, and you may form a weak conception of our prospects. I will only speak of two out of 15 or 20 of our mines. The Gun-Sight, owned by Mr. J. B. Osborne, down 80 feet; an unbroken ledge the entire depth of eight feet in width; ore averaging \$600 per ton; under the management of John Taylor, formerly foreman of the American Flag, of your place, and of the Tehipia, a continuation of the Gun-Sight, with a solid ledge of magnificent smelting ore of a very high grade, some six feet in width. Then we have the Alexander, the Balance, the Noonday, and the Sherman, owned by Silas Pierson & Co., and a host of others, but we do not ask any one to believe us unless they choose. There has never been an effort made to induce immigration, and there is none being now made. Only wait a few short months, and you will see a stream of bullion rolling from Resting Springs district into the avenues of commerce that will astonish the mining world.

GRANITE.—There is a granite quarry near Rough and Ready, in this county, that turns out the finest building stone in the State. It is by far superior to the granite of the quarries at Rocklin and Penryn in Placer county, and is better than the stone of the same name that is in the northern part of this county. Persons who are posted in such matters inform us that the Rough and Ready granite is equal, if not superior to any found in New England. Some of these days the cities below will be calling on the Rough and Ready quarries for splendid building stone. That will surely be the case when samples of it are sent to the architects and builders of the larger cities. In the Masonic and Odd Fellows' hall of this place can be seen samples of the stone that have defied time and weather and that have experienced considerable heat from fire without being changed.—*Grass Valley Union*.

MECHANICAL PROGRESS.

System and Cleanliness in Machine Shops.

Order and cleanliness in machine shops and manufactories may be advocated for higher reasons, and yet none is more convincing than the method which shows the economic side of the question. A writer in the *Polytechnic Review* has some sharp points to make on this subject and we quote as follows: A workshop, however small, however few the number of hands, is never too small to have a system; want of system is the cause of great waste of time and material, besides constant worry and discontent. Step inside this building of fair dimensions, whose front is covered with big lettered signs, showing that it is devoted to the production of all kinds of machinery.

What do we find? The floor covered with litter, heaps of cuttings under ever lathe or machine, under every bench; on the floor new and old material of all kinds have been thrown in almost inextricable confusion; the machinery is encrusted with oil and dirt, except just those parts that meet the hand in working, and the speed cones and pulleys polished by the running belts, showing what might be and is not.

The cutting tools, the bolts and plates, and other gear used in these machines, lie around their bases; a new strata seems to be fast closing over some of them. Overhead is heard the harsh grating of some loose pulley; the belts have been thrown off others by some sensitive workman, who cannot bear the unpleasant noise in such cases; the belts dangle from the shafts, the running shaft keeping a stretch on them and wearing them all the time. About 30 men are employed in these works, yet there is no one whose special duty it is to look after the tools, to replace or repair them when lost or broken.

A man has to drill a three-quarter inch hole in a piece of plate; the time actually required would be about five or ten minutes if good order were kept on this case. The man commences by making a tour of the shop, for there are some drills lying around this machine, and some around that, and there is no one place where every drill not in use is sure to be found. His search is not crowned with immediate success; a three-quarter clearing drill (13-16ths) is the nearest he can procure; he has set his callipers and taken the size of it; he proceeds to grind it to three-quarters; having reduced it to the size, he finds it will not clear itself so high as he wishes; however, at last, by more grinding, he is satisfied with it, and is ready to commence—time lost, 20 minutes. He is hardly through drilling, when up comes a man looking for the three-quarter clearing drill he was using 25 minutes ago; he, finding it has been altered, takes it to the smith, and waits to have it flattened out, which, with the re-grinding, makes a further loss of 20 minutes—total loss, forty minutes on the drilling of a three-quarter hole, for which the boss could scarcely charge more than 10 cents.

Another has a brass to plane; no tool for brass seems to be visible; he has probably trodden it down too deep in the thick red dust of the flooring to be distinguishable. However, he soon grinds off the top of a tool for cutting wrought iron; that is easy enough; but when that tool is wanted again to work in the material it was made for, 1-16th of an inch must be ground off its facets to restore the original angle—waste of time and steel.

If a workman should happen to drop a small pin, washer or key, he makes another, because among the debris around he knows it is as much lost as though when it fell the earth had gaped to receive it.

WEIGHT OF A LIFE IN COAL.—We see in the English discussions concerning loss of life in coal mining the following statements: The real cause of this yearly sacrifice of lives is the use of gunpowder in fiery seams. There is a want of precaution amongst miners in employing this explosive, and until they can be brought to understand what their negligence may bring about, "drilling-out shots" and other forbidden acts will continue to be done when deputies are out of sight. Mr. Wynne, in his report for 1875, says that in his district falls of coal and roof have caused 14 accidents, by which 14 lives have been lost, and, compared with the loss of the previous year, 23 lives, this is a very clear proof that making managers responsible for the absolute safety of the working places of the mines has had a very salutary effect. In the year 1868, a death occurred for every 103,429 tons of coal raised in England. In 1875, 108,918 tons of coal were raised per life lost; in 1868, 104,566,959 tons of coal were raised in Great Britain, involving a total loss of 1,011 lives, and in 1875, 133,306,485 tons, with a total of 1,224 lives lost, but more men were employed and more mineral raised.

BETTER TIMES IN NEW YORK.—It is stated as an evidence of the improvement in the times, that while four months ago there were 50,000 idle mechanics in New York city, there are now not more than 15,000 men out of employment. The president of the Trades Assembly, it is said, regards the condition of the workmen as better than it has been any time for three years past.

Important Improvement in Submarine Telegraphy.

A Paris letter in the *Boston Advertiser* thus describes Tommasi's invention, which is expected to effect a revolution in the methods of ocean telegraphy: The transatlantic cable requires the use of very feeble currents, as the only means of avoiding combustion or oxidation of the wires, and this feebleness of current necessitates the use of a compass, placed perpendicularly in a dark room opposite a blackboard, upon which a strong ray of light permits the operator to follow the movements of the needle and take down the dispatches as they arrive. Not only is this system fatiguing and slow, but it leaves the sender and receiver of a dispatch quite at the mercy of the telegraph operator, whose slightest inattention may result in an error over which there is no control. Constant accidents of this kind have abundantly proved the necessity of some new improvement, which leads us to hope the Marquis Tommasi's invention will be a source of universal satisfaction. The present cables, wires and batteries can be employed, and the current be reduced to one-sixth its present force; the dark room is done away with, and every guarantee and security of control given, as the dispatches arrive printed as well from Europe to America as from New York to Washington. The whole system depends upon the extreme sensibility and obedience of the magnet needle, which, forming part of a condenser, is perfectly under the control of the manipulator, who can direct the needle from right to left or from left to right. A magnetized regulator placed above the needle recalls it automatically to its normal direction after each shock. On each side of the needle is placed a flexible fine steel blade, which it touches when itself moved by the electric shock, and this movement is again communicated to a second battery of any amount of force necessary for printing the dispatches received. These second batteries are placed at both extremities of the line, and serve not only to print the dispatches but to control the operator's exactness, and as they are independent of the cable their power can in no manner injure the cable wires.

FLUX FOR WELDING STEEL.—An intelligent reader of the *Manufacturer and Builder*, who has had extensive experience in welding steel, and steel to iron, communicates the following formula and manipulation of the heated metals to be welded. He says: "To one part of flour of sulphur add two parts of sal ammoniac and 10 parts of borax. After having pulverized these ingredients, mingle the mass thoroughly in an iron kettle, put it over the fire, and continue a steady heat until every particle is melted. As soon as all the spume has disappeared from the surface, the flux should be poured out into another vessel and allowed to cool. Now reduce it to a fine powder, and it will be ready for use. When two pieces of steel are to be welded, the ends should first be heated to redness and all rust and scales be removed by filing or grinding, after which let the metal be heated in a clear and steady fire of charcoal until a welding heat is attained, when the heated steel will appear of a bright yellow. Great care must be exercised lest the surface of the steel be raised to a degree of heat above the welding point, which is always ruinous to good steel. Now sprinkle some of the flux on the heated bars, remove all scales, return the parts to the fire, bring them carefully to a welding heat, and unite the clean, smooth surfaces beneath the hammer. A skillful smith who has had but a limited experience in welding, will be able to perform a satisfactory job with little difficulty when welding steel to steel, or steel to iron."

CAR HEATING.—A new French combustible compound has a base of carbonized tan or wood bark, and this is mixed with a small quantity of nitrate of lead or spirits of niter, slaked lime or loam being added as agglutivative matter. It ignites easily, burns gradually and continuously in this state, and still slower by adding a small quantity of wood charcoal dust. Neither smoke nor odor are perceptible. A small quantity burned in a foot-warmer or chafing-pan, with a limited supply of air, will not be entirely consumed for about 16 hours, and during that time will develop heat enough to warm a compartment of an ordinary carriage. The dangerous railroad stove may be succeeded by an improvement on some such mode of heating as this. It may be that steam pipes, supplied with either live or exhaust steam, and connected with flexible gutta percha pipes, might be much better, but it is certain that some general provision of safety from this source of danger to life and property is needed.

NEW HORSE-SHOE.—Mr. Yates, of Manchester, England, has invented a horse-shoe composed of three thicknesses of cow-hide, compressed into a steel mold and then subjected to a chemical preparation. It lasts longer and weighs only one-fourth as much as the common shoe; it never splits the hoof and has no injurious influence on the foot. It requires no calks; even on asphalt the horse never slips. It is so elastic that the horse's step is lighter and surer. It adheres so closely to the foot that neither dust nor water can penetrate between the shoe and the hoof.

SCIENTIFIC PROGRESS.

Transparent Gold.

In the course of a lecture on gold, delivered before the Franklin Institute, as reported by the Secretary, Mr. A. E. Outerbridge, Jr., of the Assay Department of the Mint in Philadelphia, gave an account of some experiments he had made, with a view of ascertaining how thin a film of gold was necessary to produce a fine gold color.

The plan adopted was as follows: From a sheet of copper rolled down to a thickness of 5-1,000ths of an inch he cut a strip two and one-half by four inches. This strip, containing 20 square inches of surface, after being carefully cleaned and burnished, was weighed on a delicate assay balance. Sufficient gold to produce a fine gold color was then deposited on it by means of the battery; the strip was then dried without rubbing, and re-weighed, and found to have gained 1-10th of a grain, thus showing that one grain of gold can, by this method, be made to cover 200 square inches, as compared to 75 square inches by beating.

By calculation, based on the weight of a cubic inch of pure gold, the thickness of the deposited film was ascertained to be 1-980,400th of an inch, as against 1-367,650th for the beaten film.

An examination under the microscope showed the film to be continuous and not deposited in spots, the whole surface presenting the appearance of pure gold.

Not being satisfied, however, with this proof, and desiring to examine the film by transmitted light, Mr. Outerbridge has since tried several methods for separating the film from the copper, and the following one has proved entirely successful: The gold plating was removed from one side of the copper strip, and by immersing small pieces in weak nitric acid, for several days, the copper was entirely dissolved, leaving the films of gold intact, floating on the surface of the liquid. These were collected on strips of glass, to which they adhered on drying. When viewed with transmitted light with the microscope, it was seen to be of the characteristic bright green color, and very transparent. Viewing it by means of reflected light its true gold color is seen.

Mr. Outerbridge has continued his experiments, and, by the same processes, has succeeded in producing continuous films, which he determined to be only the 1-2,798,000th of an inch in thickness, or 10,584 times thinner than an ordinary sheet of printing paper, or 60 times less than a single undulation of green light. The weight of gold covering 20 square inches is, in this case, 35-1,000ths of a grain; one grain being sufficient to cover nearly four square feet of copper.

How to Prepare Botanical Specimens.

The following hints on this subject in the *English Mechanic* are clear and practical, and on some points the best that we remember to have seen:

Small plants should have the roots; and, if possible, obtain a specimen of each at different seasons—the young plant, in flower, and when the seed or fruit is nearly ripe. Get a quire of good thick blotting-paper and a couple of large boards and paper on which to mount your specimens. Let the boards be about the same size as the blotting-paper. Demy paper of good quality is the best size for mounting. Arrange your plants between the sheets of blotting-paper—some plants require several thicknesses—and see that the leaves, etc., are properly disposed on the paper, as you will not be able to alter them when they are dry. It is a good plan to interpose a few sheets of card-board, as it prevents one plant from spoiling another. When your drying-paper is filled, put the whole between your boards and subject to pressure; take them out every 24 hours, and dry the paper, correcting any displacement as you go on; when dry they are ready for mounting. Don't gum or paste them to the paper, but make short slits with a penknife under the stalks about one-eighth of an inch long. Take a piece of paper, as broad as the slit is long, fold the paper, and pass it over the stalk and through the hole at the back, and gum the ends on the back. I have seen every (I think) method of mounting, and this is certainly the neatest and cleanest. After this they must be painted with the following preservative solution: Corrosive sublimate, 20 grains; camphor, 20 grains; rectified spirit of wine, one ounce. This is a deadly poison, and should be handled very cautiously. Each sheet should have a neat label in the corner stating date and place of collection, and name of collector, also general habitat, specific and generic names, with natural order, etc. Without these particulars they will (as a collection), be perfectly valueless.

GLACIAL ACTION.—The last English Arctic expedition promises to confirm the views of glacialists respecting the origin of the Parallel Roads of Glen Roy, in Scotland. In Greenland nearly every valley shows similar terraces, which have been found in fresh-water lakes, kept in place by barriers of pack-ice. That represents perfectly the condition of things when the Ben Nevis glacier dammed the valley of the glen, producing an extensive lake.

Heat.

In resuming his lectures at the Royal Institution, London, Prof. Tyndall, having caused a ball of lead to fall from the roof of the theater on to a stone, drew the ball up again and let it down gently with a string and pulley. The heat generated by the collision in the first instance was the exact equivalent of the heat produced in his finger and thumb and in the string in the second instance. The outlay of the muscular force expended in drawing up the ball was made obvious by causing the ball to be drawn up again by a small engine worked by compressed heat. The exact equivalent of the heat evolved by a quantity of coal, completely consumed by consumption with oxygen, sufficient to lift a weight of 50 tons to a height of 100 feet above the earth, would be produced by the collision of that mass with the earth when allowed to fall. Given the velocity of a body, the heat generated by the destruction of that velocity could be easily calculated, and some time ago he was led to the conclusion that the stoppage of a rifle bullet would produce sufficient heat to fuse the metal. This conclusion was proved in the Franco-German war, when bullets which had been stopped by contact with a bone, showed on being extracted undoubted marks, in many cases, of a fusion. The same thing had also been illustrated incidentally in the experiments with gun cotton at Stowmarket. The old notion of heat was that it was a substance which could be squeezed out of matter as water was squeezed out of a sponge. A bullet squeezed in a hydraulic press acquired heat, which was rendered obvious in the galvanometer by the thermo-electric pile. Even as late as the time of Faraday, it was conceived that heat was something for which some bodies had a greater capacity than others. If compressed air from one vessel was allowed to pass into a vessel in which the pressure was much less, it would have been said that the motion of the air gave to the comparatively empty vessel a greater capacity for heat. The heat thus produced was shown by means of the galvanometer and thermo-electric pile; but the reason for that heat was, said Prof. Tyndall, quite differently understood now. The coefficient of the expansion of gases was next described with some minuteness; and, continuing the illustration of what used to be termed "capacity for heat," the lecturer said the explanation of different metals, when subjected to the same degree of heat, not possessing in themselves the same amount of heat, was that heat had two operations—one, the production of tremors (which was heat), the other the weakening of molecular attraction. Thus, if lead and iron were exposed to the same high temperature the lead would be much hotter than the iron, because in the former case less internal molecular work was performed, and more heat was expended in the production of tremors; while in the latter case more heat was used up in internal work, and less in the production of tremors. The same degree of heat was in operation, but the apparent results were different, and hence grew up the very natural notion that different bodies had different capacities for heat.

IN AFRICA.—News, says *Nature*, has been again received at Munich, after a long time, from the African traveler, Dr. Erwin v. Bary. He had safely returned to Ghat from his journey into the Valley Mihero. He is the first European who has visited the hot springs of Sebarbar and seen the crocodile-pond. Interesting geological and geognostic results, with a collection of many hitherto unknown plants, have been gained from this journey. It was very dangerous, owing to the war of the Asgar with the Hogar of Tuareg, and the traveler was in constant risk of attack. The sheikh of Tuareg, Jehenuchen, 102 years old, has lost two sons; so he is not easily propitiated. The murderer of the Dutch traveler, Alexandrine Tinne, whose unhappy fate excited European sympathy, goes about freely in Ghat. Dr. v. Bary will endeavor, notwithstanding the danger, to penetrate further into the country of the Tuareg, in order to prosecute his geological and botanical inquiries.

WOODRUFF SCIENTIFIC EXPEDITION.—We have received a copy of a pamphlet describing an enterprise which bears the above name. The plan is to charter a steam vessel and carry a load of professors and students around the world on a two-years' cruise of scientific study and observation. The plans are all laid and the ship will sail from New York city October 1st, 1877. Among the professors who will embark we notice Prof. B. G. Wilder, of Cornell; Prof. W. G. Farlow, of Harvard; Prof. S. I. Smith, of Yale, and half a dozen others. The enterprise is under the management of Mr. James Woodruff and Gen. Daniel Macanley, of Indianapolis, Indiana. We believe that applications for students' places in the floating university are still acceptable and full information can be gained by addressing the managers at the place named.

JURASSIC FAUNA.—Dr. Herr shows in a recent publication that along the shores of the Amoor, in Siberia, is the finest development known of Jurassic plants, amounting to 83 species. Like those from Yorkshire and Spitzbergen, the conifers, *Salisburia*, and tropical forms predominate. Of existing forms we recognize *Asplenium*, *Thyrsopteris* and *Dicksonia*.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

OLIVE.—Amador Ledger, June 17: The clean-up last week did not result so favorably as was expected. From what we can gather, it was sufficient to cover expenses. The rock is now being taken from a depth of 80 feet, and the Bonanza mill is still running on the ore.

TALMANS CLEAN-UP.—The clean-up made this week panned out splendidly, much better than any previous run, except the first, which averaged nearly \$15 per ton.

FROM PLUMCOTT.—The Phoenix company will this season put up reduction works to work their sulphurets, which amount to one and a half tons per day. We also learn from Supt. Green that last month the clean-up for 15 days' run exceeded by 100 lbs. any run made by 50 stamps. When the mill is closed down, both shafts will be sunk from 100 to 200 feet deeper, and we hope that we shall not lose any of our citizens for want of employment. Two breaks occurred on the ditch last week; one carried away 40 feet of the embankment. The breaks are now caused by floating timbers, which jam and cause breaks. From 30 to 40 timbers are now delivered daily at the mine through the ditch.

BUTTE.

GOLD.—Oroville Mercury, June 16: The dry season has not entirely cut off our gold crop. Thursday night of last week there came some \$70,000 in dust into the express office, to be sent below for coinage. The best part of the story is, that most of it came from new claims where the low water permitted the miner to open them up. This is but the first installment. We expect they will be quite frequent during the coming season.

CALAVERAS.

OWIN MINES.—Calaveras Citizen, June 16: Until recently the mining operations in the Owin mine have been confined to the south of the shaft. A short time since prospecting was commenced to the north. A drift was commenced on a level 1300 feet deep. When in a distance of about 70 feet ore was struck immensely rich. The drift is now in about 170 feet, and still holds rich. The milling capacity of the mine is 40 stamps; only 23 are being worked, putting through between 50 and 60 tons per day.

THE WATER SUPPLY.—Calaveras Chronicle, June 16: The water famine is approaching. We understand that there is only about 400 inches of water in the ditch, and it is decreasing rapidly. Another week or two of warm weather will cut off the supply altogether, unless the water company can make arrangements for the contents of the Sandy Gulch ditch, for which we understand they are negotiating. All the hydraulics are making haste to finish cleaning up while there is water enough left to "wash down" their dunes.

CONSOLIDATION.—We understand that the Good Hope and San Bruno mines, at Mosquito, are to be consolidated under the control of a San Francisco company. The two mines are on the same ledge, and the plan is to connect them with a tunnel, which, when completed, would admit of the employment of any number of hands.

URSA COXNEY TRAIL.—Times continue exceptionally brisk in the upper country, especially at West Point and vicinity. The mills are all in active operation, and a good deal of money is being taken out. A large amount of capital is being invested, and the developments made are flattering and encouraging. Champion, still crushing and sinking. Rock sufficient to keep the mill employed until middle of August is already mined. The ledge is widening as the shaft goes down. The crushing of rock from the Granite is concluded, and the Supt. has gone below to arrange for the purchase of the mine. The ledge is 18 feet wide, the rock averaging \$7.50 per ton. The new mill at the Zacatero will be ready to start up next Monday, and there is any amount of rock in the vicinity waiting to be crushed. At Railroad, Clark's mill is kept running on rock from the Sundermiller mine. Operations have been temporarily suspended at the Chapman mine in consequence of the inability of the pump to keep the shaft free of water. A new pump will be put in as soon as practicable. At Mosquito Garland's mill will be started up next Monday on rock from Gass & Co.'s mine. Lamson has also a crushing out and will commence hauling to the mill immediately.

COLUSA.

MANZANITA.—Cor. Lower Lake Bulletin, June 12: The Manzanita (gold and quicksilver), is doing well under the management of Mr. George Senn, the enterprising Superintendent. Mr. Senn deserves much credit for his energetic effort to develop it into one of great worth, which it has already proved itself to be. The mine is turning out considerable quantities of very rich ore in gold, and the tailings pay well in quicksilver—being reduced by a process recently adopted. I have heard it asserted that the company intend very soon to increase their milling capacity, which, when put in operation, will insure employment for a considerably larger force, by which the laboring class in this section will be very materially benefited.

THE BUCKEYE (quicksilver), is in successful operation, employing a large number of men; only a small number are Chinese. Mr. H. Caswell, the Superintendent, has displayed great skill in re-opening the mine, which was greatly damaged by a cave during the winter of 1875-6, and which almost entirely cut off communication with the best bodies of ore. The facilities for extracting the ore are at present greater than ever before. The company are now constructing a fine-ore furnace, which the Superintendent thinks, when finished, will at least double the present production—the best ore being contained in the "fine dirt," of which they have now on hand a large quantity.

INYO.

MODOC.—Coso Mining News, June 16: If the accustomed car-load of bullion is not received in San Francisco for two or three days the present month, parties interested in the Modoc need not become frightened in the least, for they have only shut down for a day or two to make repairs to the engine and furnaces, which had become somewhat demoralized after so long and hot a siege. Probably will be running with accustomed regularity before this issue of the News is read in San Francisco.

BULLION SHIPMENTS.—Inyo Independent, June 12: The season of Rex Montis bullion shipments has opened. Superintendent Holt having shipped fine bullion to the value of \$2,800 during the past two weeks. With our knowledge of the value of the ore, it is not far from probable that Rex Montis will prove to be for the present season the most productive five-stamp mill on the coast.

PIUTE DISTRICT.—A pack train of 14 mules passed through town during the week, from Lone Pine, bound to the Johnson mill in Piute district, near Bishop, where they are to be employed in transferring from the mine to the mill about 200 tons of ore on the dump at the mine. The mill has been thoroughly reconstructed, and it is very probable that when the works start up this time it will be to some effect.

LITIGATION.—The Hidalgo mine in Darwin, which is included among the properties of the Santa Rita furnace company, seems about to be involved in serious litigation. Thomas Sheridan enters a complaint in the United States Circuit Court praying judgment against Tinoco, Fortune, et al, for possession of the mine, \$50,000 damages and costs of suit.

THE ECLIPSE.—Superintendent Nelson of the Eclipse has gone upon a flying visit to San Francisco, on business pertaining to some suits brought against the company, wherein the mill and personal property were attached. Bonds were promptly given releasing the property, and

Mr. Nelson has gone to get funds to pay off the debts, or at least such as he thinks are just.

LAKE.

UNCLE SAM.—Lower Lake Bulletin, June 10: From H. R. Callahan, Superintendent of the above-named quicksilver mine, situated on the southeast slope of Uncle Sam mountain, and about 10 miles from Lower Lake, we learn that work will be resumed immediately on the mine—a force of 10 men having already been engaged. Ten tons of ore will be shipped next week via Lower Lake to Sulphur Bank to be treated to test its percentage. Five tons are already in the dump, the other five will be taken out during the week. Mr. Callahan informs us that the prospect is excellent, and that it is the intention of the owners to give the mine a thorough test.

NEVADA.

GOLD DIRT.—Nevada Weekly Gazette, June 16: The North Bloomfield gravel company shipped by Wells, Fargo & Co., on Sunday morning last, over \$400,000 worth of gold dust, the proceeds of the last 15 or 20 days' run. The mine is just beginning to be opened so as to allow of profitable work. Next year the proceeds ought to be double that of this year. What a glorious thing it would be if the money taken out of the county could be kept here. Millions of dollars may be extracted from the ground yearly, but very little sticks to the county. Capitalists are needed to develop the resources of the county, but it would be better if local capitalists should do it, for then we would have more ready cash in circulation than any place in the world.

In the town of Eureka South is located the Blackhawk ledge, which is a set of rich wash and the rock from it is heavily charged with sulphurates. It is owned by A. Cochran, who is unable to put up machinery upon it, and would dispose of a liberal share of it for such purpose.

We saw some rock yesterday from the Black and Young ledge, located about one mile from Eureka South in this county, in a place called Rocky Glen, which shows gold very liberally, and it is thought will pan out first-rate. It is owned by John Dillbert. He has taken out a lot which is being worked at the mill.

ALASKA MINE.—Grass Valley Union, June 16: The Alaska is proving itself to be a pretty good mine. A clean-up was completed yesterday and the showing is good. Fifty-five loads of rock were milled, and gold to the value of \$5,000 was the result. This does not include sulphurates. The Alaska company have a strong and well defined ledge, which pays by mill process \$34 to the ton. That sort of affairs must be gratifying to the stockholders. Many Sacramento men are in that lucky list. The Alaska is superintended by Mr. Dodsword. It is confidently expected that a nice little dividend will be declared in July.

GRASS VALLEY NEW.—A fine ledge was struck in the shaft of the Grass Valley New mine on last Friday. The ledge is two feet in thickness and the rock has a fine appearance. Good judges pronounce it to be a good millable ore. The Grass Valley New is located near the Nevada road about a mile from Grass Valley. It has generally been facetiously termed the Gimlet, but we guess that name will now be dropped.

OAKLAND.—Active and regular work on this mine will begin this week. A water wheel which will drive a pump and enable the mine to be worked 200 feet in depth is to be put up, and by that time the owners confidently anticipate having gold enough on hand taken from the mine, to put up machinery of any capacity that may be required. The ore that has been taken out so far certainly justifies the anticipation.

GOOD PROSPECT.—Mr. Silvester is having his cellar under his store enlarged, and of course a good bit of dirt has to come out. The other day a friend of ours tried that dirt with a pan and found it pretty rich with gold. Had all the dirt been taken out and hauled through a sluice, gold enough to help materially to pay for the cellar enlargement would have been realized. Grass Valley's streets are paved with gold-bearing rock and its houses are built on gold-bearing earth and rock.

GOLD.—Nevada Transcript, June 16: A gentleman who claims to know, informs us that about \$100,000 in gold bars have been shipped to San Francisco from this city during the past week. Most of it came from Bridgeport and Bloomfield townships. Our mines are not quite played out.

BULLION.—On Wednesday afternoon the San Juan stage brought over a large amount of bullion from the Ridge. Sim Johnson, the express driver, had a little more than he could carry across the sidewalk to the wagon. He is a pretty stout man and we should judge there must have been in the neighborhood of \$30,000 in the express box.

PLACER.

THE SEASON.—Dutch Flat Forum, June 15: Since our last issue we have been having hot weather, which has caused the snow on the mountains above to disappear and we fear, hasten the close of the washing season. The various camps on the river have been working with unusual vigor, the Superintendents apparently realizing the importance of improving the remaining time.

The Star and Union have been off since the 1st inst., pending the driving of a powder drift into the point of gravel at the head of its rock cut, which was completed, the blast exploded on Monday and washing resumed on Tuesday. This claim has done well this season, notwithstanding the fact that the fine gravel has been removed. There still remains from three to six feet of the lower strata next to the bedrock, which we understand it is the intention to work off after the water falls.

The Baker claim continues washed on the gravel loosened by the blasts that were exploded in the latter part of April. Thus far only the top gravel has been removed, and it will take about three weeks yet to work off the bottom. At the largest one of these blasts was in a drifted ground, the result is looked for with considerable interest.

The Franklin is lying off running a powder drift. The Polar Star and Southern Cross are again running smoothly, using a large head of water, which is alternated between the two, one using it while the other is removing boulders. The Pacific is off owing to a scarcity of water. The Elmore Hill claim continues washing, but expects to put pieces worth from \$1 to \$7. They claim, however, not to be into their best ground yet. They are working gradually up the ravine, and expect soon to reach a piece of virgin ground that they think is good.

A. T. MOLIN is sinking away on a ledge near the old Calf Pasture, a mile or two north of Auburn, and though he keeps very quiet it is generally understood that he has a good mine. Only a week or two ago he crushed out 25 or 30 pounds of rock, which yielded him a little over \$4 per pound. Indeed it is understood he is realizing big wages from what he pounds out in a hand mortar between regular working hours, to say nothing about the good milling ore that he is taking out every day.

PLUMAS.

ANOTHER STRIKE.—A week or two ago we spoke of a fine prospect in a new ledge discovered between Soda creek and Long valley, or the head of Rush creek. It is owned by Geo. W. Williams, and the developments being made indicate that there is a first-class mine. The rock shows more free gold than any quartz in that section.

MIDDLE FORK.—The waters are fast receding to summer standard, and in a short time the Middle Fork will be way below the usual summer flow. Many old miners are now looking up and refreshing their memories about rich places in the river years ago, with a view of trying it once more, as this will be the most favorable year that has happened for a decade, if not the driest ever known. Mr. Swan is working a high bar, and has five or six men at work. His prospects are promising. Mr. Culver, of Hardscrabble, has leased his claims for the season, to Geo. Cass & Co. The Jackson Brothers, of the same locality,

are at work. Mr. Mason will enlarge his Long valley ditch this season. Mr. Hanson worked his claim for a short time this spring, with but little over half a head of water, and that too, in our most cold and stormy days. The result was entirely satisfactory, and will justify any outlay for improvements. If those San Francisco men, who are laboring to revive their defunct stock boards, would advise their capitalists to come to Plumas county and stop one month, and then invest on merit, and work the ground for the profits, in one or two years we would show the "cloud-hoppers" of any county in the State, who would have the largest purse.

SIERRA.

THAT BOMB.—Mountain Messenger, June 16: The Pioche mining company commenced boring on Wednesday last, and made 17 feet the first day. The machinery worked as well as could be expected, for a starter. Work will progress more rapidly when everything is in running order.

OREGON CREEK.—The Bald Mountain company has purchased the creek claims of Treloar and Lee, at Forest city, and will hereafter dump their tailings into the creek instead of running them through a mile of dunes. This will enable the company to work to much better advantage than ever before. The consideration is said to be \$11,000.

MONTICRISTO QUARTZ CO. are still engaged in pushing forward their bedrock tunnel, at Monte Cristo. They are in 220 feet, and have about 70 more to run before tapping the ledge, which will be accomplished early in August. Another when used to 30 feet below the creek, the quartz ledge, and the quartz looks splendid. San Francisco, Oakland and Stockton capitalists are interested in this mine.

TRINITY.

PAID WELL.—Trinity Journal, June 16: The Weaverly ditch and hydraulic mining company finished cleaning up in the Ward mine, on Oregon mountain, last week. Dust was taken out to the amount of \$4,300, which added to the result of a previous clean-up makes over \$8,000 as the result of the season's work. Superintendent Lovelidge tells us that the whole run of water for the season was only 300 hours, the average product of the mine therefore being at the rate of over \$25 a day. It is a pity that more water is not taken to that mine. There is enough rich ground there to pay for the construction of a long ditch.

"LUCK."—Miners are somewhat superstitious. One of our old chums used to swear "by Jolly" that the gold moved out of a claim if a certain unlucky devil happened to come there to work, or even looked over the bank. Another who used to 30 feet below the creek, the quartz ledge, and the quartz looks splendid. San Francisco, Oakland and Stockton capitalists are interested in this mine. It is a pity that more water is not taken to that mine. There is enough rich ground there to pay for the construction of a long ditch.

Nevada.

WASHOE DISTRICT.

CONR. VIRGINIA.—Gold Hill News, June 20: Daily yield 500 tons of ore of the same rich quality as that that heretofore extracted and milled. The ore stops on the 1500, 1550 and 1650-ft levels are both looking and yielding well at every point. The southeast drift from the ore stops on the 1650-ft level is still showing good ore. The east drift from the deep winze on the same level is also in fine ore. The ventilation of the 1650-ft level has been greatly improved by a strong current of air that passes from the 1550-ft level on forward through the shaft through the Consolidated shaft. The ore breasts and stops on the 1400-ft level are yielding splendid ore, and are showing rich as they are opened up further to the northward. Sinking the C. & C. shaft has been resumed.

CALIFORNIA.—Daily yield, 550 tons of ore. The ore stops on the 1600, 1500 and 1550-ft levels are showing splendidly at all points, and yielding rich ore. The north drift from the deep winze on the 1650-ft level is steadily advancing, and will connect with No. 4 winze in a day or two more. The large winze below the 1650-ft level in cross-cut No. 5 is being sunk below the 1650-ft level, and will not be stopped until it has reached the 1840-ft level, and been connected with a drift that is to be run in the meantime from the Ophir workings. Winzes Nos. 3 and 4 below the 1600-ft level are each making excellent progress, the bottom of both still in rich ore. A drift west has been started at a depth of 60 feet in winze No. 4. This drift has penetrated a distance of 16 feet, the face being still in rich ore. Sinking the joint double winze below the 1650-ft level is making excellent progress, the bottom still in rich ore. The yield of bullion for this month is far in advance of the yield at the same date in May, so that the payment of the usual dividend of \$2 per share is already assured.

YELLOW JACKET.—The main drift east at the 2200-ft level was in 107 feet this morning, and still continues in hard, dry, bird-eye porphyry. Even this apparently barren rock shows small spots and bunches of black sulphurates of silver sprinkled through it. The south drift at the same level is in 112 feet to-day and shows small stringers of quartz running diagonally across the drift in a southeasterly direction. No water is met with as yet in either drift, although it might be expected at almost any depth in drifting about at that depth. The new working shaft to the eastward is to-day down to the depth of 755 feet.

SILVER HILL.—The north and south drifts on the 650-ft level are being pushed forward with all possible energy, the prospect of finding paying bodies of ore growing better every day.

GOLD & CURRY. The pumps at the 1500-ft level are doing splendid work. The plug has been withdrawn, and the flow of water from the face of the main east drift on the 1700-ft level is being gradually drawn off and the face of the drift again advanced. As soon as the water is sufficiently drained the other cross-cuts will be forwarded in every portion of the mine and the value of the east ore vein determined in a very short time.

LEVATHAN.—Cross-cut No. 3, from the south drift at the 600-ft level, has been extended at least 30 feet through good ledge matter. Fine stringers and bunches of quartz are being constantly run through.

SOLID SILVER.—Work is resumed in this mine, which is situated on the north end of the Comstock range, in Cedar hill. From the main tunnel or adit, which is 1,200 feet in length, running north into the hill, following the ledge, cross-cutting is being done, both east and west, in excellent ore indications.

ALPHA CON.—The north drift on the 2000-ft level has penetrated to the Exchequer line, so that cross-cutting the ore vein in that portion of the mine is next in order. **BEST & BELCHER.**—The mine was never in as cool and fine a condition for rapid developments on the 1700-ft level as it is to-day. In a day or two more the east cross-cuts in the 1700-ft level will have drawn the head of water, and enabled the starting up of all of the prospecting drifts in that portion of the mine.

BELCHER.—Daily yield, 80 tons of ore, keeping the Santiago mill running, and making a reserve on which it is the intention to start up the Kelsey mill in a very few days. The east cross-cut from the south drift on the 1600-ft level is showing some good ore.

UTAH.—The south drift on the 1150-ft level is being pushed vigorously forward, the face still in quartz of a fine character. This drift will be driven forward until it connects with the north drift from the Sierra Nevada on the 1200-ft level.

BULLION.—Sinking the main incline below the 1500-ft level is making the best of progress. The north and south drifts on the 1600-ft level are each steadily advancing, the face of either drift in a fine character of ledge material.

OPHIR.—A small Cameron pump has been put in at the south winze below the 1700-ft level, as it was found that the flow of water could not be kept down without it. The bottom of this winze is still in very favorable quartz and ore.

IMPERIAL CON.—Sinking the south winze near the Yellow Jacket line is making the usual fair rate of progress, the bottom being in very favorable quartz and ledge matter.

MEXICAN.—The joint winze on the Ophir line is making the best of progress, the bottom following the foot wall of the ledge and showing some very fine quartz and ore. The east cross-cut on the same level is in very soft, favorable material.

ATLANTIC CON.—The main tunnel is being pushed vigorously ahead, the face in quartz of a fine character. The progress made is excellent, and the tunnel will in all probability strike the ledge at a depth of 50 feet below the present workings in running a distance of 50 feet further.

SIERRA NEVADA.—The south drift on the 1700-ft level is showing a very encouraging improvement. The winze now being sunk below the 1500-ft level, in the southern portion of the mine, is also showing some quartz.

JUSTICE.—Daily yield 450 tons of ore, keeping the mills all steadily running up to their full working capacities. The ore stops from the 400 down to the 700-ft levels are all yielding the regular amount of paying ore. The winze below the 800-ft level continues in excellent ore. The ledge and ore on the 1000-ft level is showing splendidly and promises a rich harvest.

JULIA.—The main south drift on the 1500-ft level is showing better ore than for some time past, and the indications are that instead of having passed through the best portion of the quartz and ore body on that level, that this drift is but just reaching its outskirts.

ALTA.—The shaft has reached a depth of 1050 feet, at which point it is the intention to open a station and run a drift to the ledge.

OVERMAN.—The main south drift on the 1300-ft level is making splendid progress, the face in fine quartz and ledge matter.

HALE & NORCROSS.—The water is reduced to a point 100 feet below the 1000-ft level.

LADY WASHINGTON.—The back wages due to the workmen at the time of suspending operations have been paid in full, and everything is being put in order with a view to resuming work in the mine as early as possible.

NORTON CON. VIRGINIA.—The extraction of the water has proven more of an undertaking than was at first expected.

CHOLLAR POTOMI.—Daily yield, 110 tons of ore, the average assay value of which is \$24.50 per ton.

UNION CON.—The north drift from the bottom of the winze below the 1300-ft level is making good headway, the face in ledge matter of a lively character.

SUTRO TUNNEL.—The header is running in very favorable working material, which drills and blasts well. It is principally ledge matter, requiring careful timbering. Streaks of low grade ore are quite frequently met with.

CALIFORNIA.—The north drift on the 1600-ft level is being pushed forward with all the vigor possible.

GROWN DIST.—The south drift from the main east drift on the 2000-ft level, now running in connection with the combination Belcher air and drain shaft, is being pushed ahead with speed.

SAVAGE.—The pumps are doing splendid work, and are kept running at the top of their speed. The water is now down 98 feet below the 1900-ft level, measuring the distance by the incline slope of the mine.

AYTON.—The men at the mine have received their pay in full, and preparations are being made to start the entire mine into full operation again.

CORNUCOPIA DISTRICT.

THE MINES.—Cor. Silver State, June 18: I do not know of anything new to say about the mines, only that those who think they know say that the present developments in them indicate greater prospects than have been seen ever before. There are a good many men employed, although the bullion shipments appear to be light, but will increase shortly. Some new locations have been made lately in this district, one, a new discovery, running across the Leopard, has been located by Phil Sullivan and others, which prospects well at the depth of 20 feet, as far as they are down at present. Another location has been made north of town which shows well on top. I had thought I could give you some items of interest from Mountain City when I saw Mr. Plummer of that place. He was here a few days ago, and speaks very encouragingly of that locality, but says that it will take time and money to develop it. He is going to stay there, being fully convinced that he will see the day when it will excel the days of its glory. He would not advise broken men to come there, unless for the parties who are working claims are not now prepared to employ everybody that comes along.

ELY DISTRICT.

ALPS MINING CO.—Pioche Record, June 16: Work progressing vigorously on the Washington & Creole and Maizeppa mines; a large force being employed working and extracting ore, of which 50 tons were shipped to the Concord mill during the week, and 50 tons more will be shipped either today or Sunday. Everything about the mines is looking well, and as the company will get well to work by the 1st of July they expect to make a good showing.

RAYMOND & ELY.—There is good progress being made all through the mine and the lower level is looking very well. The mill at Bullionville started 15 stamps to work on Monday. None of the ore from the lower level has yet been worked, as for the present they are confining themselves to ore from the upper levels.

HIGHLAND FURNACE.—The Highland furnace closed down on Wednesday evening on account of one of the smelters becoming sick from being leaded, and there being no one to supply his place. During the run 245 bars were run off, making about nine tons of bullion. The furnace started again on Monday, there being plenty of ore and other material on hand. The ore worked on this run was from Bristol district.

EUREKA DISTRICT.

THE K. K. MINE.—Eureka Sentinel, June 15: The mine has been under the management of Superintendent Arlington since last July, during which time he has done over \$40,000 worth of prospecting and dead work. The mine was started in September and has run continuously since that time with the exception of occasional stoppages for repairs. He has shipped to date 1,100 tons of bullion, worth on an average about \$300 per ton. This has returned a net yield, including ore and coal on hand, of about \$40,000. Counting the dead work that was necessary to be done, it will thus be seen that the mine has produced, over and above working expenses, something like \$80,000 since last September. These figures are only approximately correct, but they only serve to show that the K. K. is a most valuable property. Still better results may be anticipated when the seventh level shall have been fully opened.

PROSPECT MOUNTAIN.—The Oregonian mine is situated on the southwest slope of Prospect mountain and contains 1,000 feet. It is opened by a shaft and tunnel. The shaft is about 60 feet deep, and contains ore of a high grade. The tunnel is about 100 feet in length, and is designed to tap the lode 100 feet below the bottom of the shaft. There is ore at the end of the tunnel. The core mine is situated below the Matamoros on the west side of Prospect mountain. It is opened by two shafts. No. 1 is inclined and is 20 feet deep, and contains ore assaying in silver \$30 and in gold \$35. Shaft No. 2 contains ore of a high grade, as shaft No. 1. The Handy Andy mine is between the Matamoros and Williams mines. It is an old location opened by four shafts and a tunnel. The tunnel 35 feet in length—is being run, and is designed to tap the lode 100 feet below the surface.

THE HAMBURG DUMPS at the furnace are full of ore, necessitating a partial suspension of work until the furnaces can catch up. A new development has been made in the north shaft, Friday No. 2, a body of high grade ore having been met with in a winze on the 400-ft level. The mine never looked better at present.

Arizona.

PECK.—Arizona Enterprise, June 13: The increase made in the force on the Peck mine has made everything

The Tea Plant.

The culture of the tea plant and the production of first-class sewing circle material may be said to be one of the California problems. We have credit in all the encyclopedias with the ability to produce good plants, but putting the production upon a practical and profitable basis is another question and is, we believe, as far from satisfactory demonstration as it was when our first experiments were made. We chose the tea plant for illustration this week because its cultivation may still be considered as among our far-off possibilities, and because, as the illustration is a good one, the publishing of it may be of interest to our amateur students of botany, and for the information of readers generally. So far as the introduction of the plant as an element of agricultural production is concerned we have again the oft repeated assertion that the Asiatic fields are showing signs of decadence. Whether the report be true or not we have no present means of judging, but it may serve as a stimulus toward the determination of our latent resources. We have no reason to believe, from the present quality and price of labor in this State, that we can produce tea profitably, and yet why is there not the same field for the introduction of labor-saving machinery in production of tea as in other complex operations which have already yielded to the achievements of inventors? It is, however, chiefly with the intention of interesting readers who are not familiar with the appearance of the tea plant that we use it as an illustration.

Our engraving gives an excellent exhibition of the analysis of the plant botanically. As we read the studies of the botanist, it is now generally agreed that there is not sufficient reason to give the tea plant a genus of its own, but it must be classified as a species of the genus *Camellia*, and its name is *Camellia thea*. The tea plant differs from the other species of *Camellia* grown in this country, according to one authority, by having "longer, narrower, thinner, more serrate and less shiny leaves. Its flowers are axillary and nodding, and though only about an inch across, closely resemble those of a single *Camellia*. The sepals and petals are usually five, the stamens numerous, a portion forming by their united bases a cup, within which are numerous separate stamens. The fruit or pod is usually three-celled, with a single large seed in each cell." These points are well shown in the engraving. At the lower left hand corner are shown the tripartite pistil, the cross section of the three-celled ovary, and the three-celled seed-pod, when fully grown. At the right lower corner are sections of the seed, with and without its covering, and one seed split to show the position of the germ.

Such, in brief, is the plant which has given China a name throughout the world. Of the growth of it in China we have the following interesting description in the words of a traveler:

In the black tea districts of China, as in the green, large quantities of young plants are yearly raised from seeds. These seeds are gathered at maturity, in October, mixed immediately after and packed in sand and earth, in which they are kept during the winter months. In this manner they are preserved fresh until spring, when they are thickly sown in some corner of the farm, whence they are afterwards transplanted. Sometimes they are sown in rows where they are destined to grow, and consequently do not require to be removed. When about a year old the plants are usually from nine inches to a foot in height and are ready for transplanting. They are set in rows about four feet apart, in bunches or hills, three or four feet asunder along the rows, with five or six plants to each bunch. In some cases, however, when the soil is poor, as in many parts of Woo-e-shan, they are planted very close in the rows and appear like hedges when fully grown.

The young plantations are always made in the spring and are well watered by the rains which fall at the change of the monsoon in April and May. The damp, moist weather at this season enables the plants to establish themselves in their new quarters, and they afterwards require but little care, except in keeping the ground free from weeds.

When the winters are very severe, the natives tie straw bands round the young tender shrubs to protect them from the cold, and to prevent them from cracking or bursting from frost or snow.

A tea plantation, when seen at a distance, looks like a little shrubby of evergreens. As the traveler threads his way among the rocky scenery of Woo-e-shan, these plantations, which are constantly seen dotting the hillsides, afford a pleasing contrast to the strange and often barren surface by their rich dark-green leaves. When young, they are allowed to grow unmo-lested for two or three years, or until they are well established and producing strong and vigorous shoots. The practice of plucking the leaves is very prejudicial to this shrub, and the natives always take care that the plant shall be in a vigorous and healthy condition before this operation is commenced. Even when the plantations are in full bearing they never take many leaves from the weaker plants, in order that their growth may not be checked. For, under the best mode of treatment and on the most congenial soil, they ultimately become stunted and unhealthy and are never profitable when old. Hence, in well managed tea districts, the natives annually remove old plantations and supply their places with fresh ones.

The Gum Arabic Tree.

We have many acacia trees in this State, and they grow well in some localities, while in others they are destroyed by a scale insect. We are not aware of the species of all the acacia trees in the State, nor do we know whether any one has the "Egyptian Gum Arabic Tree" (*Acacia Vera* L.). If not, the introduction of it would seem to be a matter of interest, and possibly the foundation of a promising industry. The locality in which the experiment might be tried would have great influence upon the result, for the tree is represented to be fastidious grower. It is said to be doing well in Florida, and Mr. Benjamin Hall gives the Florida *Agriculturist* the following interesting account of the tree: "This semi-tropical tree, or, more properly, shrub, rarely exceeds fifteen feet in height, and is remarkable for its peculiar, crooked shaped trunk. Its foliage is of a pale green color, and may be said to be the most beautiful of the acacia family. It puts forth its flowers in March, and its seeds, which grow in a hard, coriaceous pod, somewhat resembling the *Acacia jombosia*, and its seeds those of the lupine, which

hotter, incisions are generally made through the bark to assist the exudation of the gum. The gum when new emits a faint smell, and when stowed in the warehouse, it may be heard to crack spontaneously for several weeks, and this cracking is the surest criterion of new gum, as it never does so when old. Several kinds of gum, yielded by different trees, are occasionally to be met with, but that which is commonly substituted for it is brought from the island of Senegal, on the coast of Africa, and is called "Gum Senegal." This tree is remarkably sensitive to sudden changes of the weather, and its leaflets are open only to the rays of the sun. There are several trees growing successfully on the Indian river, and appear to be adapted to this soil and climate. This tree is possessed of much merit, and is worthy of culture, both for ornament and profit. It is propagated by its seeds, which can be obtained by mail, at letter postage rates, through the American Consul, resident in Cairo, or Alexandria, in Egypt."

SINGULAR FORMATIONS.—The character of the bed-rock at and near Point Bar, on Trinity river, is very different from the general run of river mines. In a general way deep places in

THE CHINESE TEA PLANT.

yields a reddish dye, used by tanners in the preparation of leather. This tree, which affords the finest gum arabic of commerce, is native of the sandy deserts of Arabia, Egypt, and the western parts of Asia; it also grows abundantly in Barbary and other parts of Africa, particularly on the Atlas mountains. In Cairo and Alexandria in Egypt, many streets are adorned with this tree, which is set on either side. In Morocco, where this tree is called "Attelep," large quantities of this gum are collected for export. The trunk of this tree is covered with a smooth, gray bark, while that of the branches is of a yellowish green or purple tinge. At the base of the leaves there are two opposite awl-shaped spines, growing nearly erect, and having a slight glandular swelling below. The wood is hard, and takes a good polish. The gum exudes spontaneously from the bark of the trunk and branches of the tree in a soft or nearly fluid state, and hardens by exposure to the air or to the heat of the sun. The more sickly the tree, the more gum it yields, and the hotter the weather the more prolific it is. A wet winter and a cool or mild summer are unfavorable to the crop. The gum begins to flow in Egypt in December, in Florida in March, immediately after or near the time of the flowering of the tree. Afterwards, as the weather becomes

the bed-rock, unless they are regular channels or crevices, pay nothing; the pay dirt not extending below the level of the surrounding rock, but continuing along in the gravel at that level. At and near Point Bar, the reverse is the case, the best and richest pay having been always found in deep depressions of the bed-rock. On Point Bar itself some four or five of these deep places have been found, filled with big boulders and blue gravel, rich in gold. The deep places are from thirty to a hundred yards long, fifteen to thirty yards in width and of a varying depth. One in the river, a short distance below the old store and garden, was twenty feet deeper than the water in the channel, and looked like a long, deep hole in the bed-rock, as in fact it was. Hughes & Wallace have found two such depressions in their claim opposite Garden Bar, one mile below, both of which prospect well; and so far as worked have paid well. It is the only place along the river that we know of, where anything like a "pothole" pays anything below the level of the surrounding rock.—*Trinity Journal*.

THEY have the leaching process in full blast at Leeds, Utah. They now leach only two tons in a day, but will soon be able to treat five tons per day.

THE ENGINEER.

The Canadian Pacific Railway.

We have heard but little lately of this great enterprise to which the Dominion of Canada is committed, but some interesting information as to the progress and position of the railway is afforded in a report just issued by Mr. Sandford Fleming, the chief engineer of the undertaking. The surveys or examinations made by Mr. Sandford Fleming and his associates have not all been of the same character, but they have varied according to circumstances. They may be subdivided under six heads: First, explorations; secondly, exploratory surveys; thirdly, revised surveys; fourthly, trial locations; fifthly, location surveys; and sixthly, revised locations. At the commencement of the survey, all the sources of information open to inquiry with regard to the passes through the Rocky mountains were consulted; and after careful examination, it appeared that two passes known as the Howse and the Yellow Head possessed advantages which, taken in conjunction with the approaches to them, called for further examination. It was evident that the obstacles which intervened between the passes and the coast of British Columbia were of a serious character, and that the selection of the pass through the main Rocky mountain range depended on the discovery of a practicable line across the whole mountain region. After various examinations, the Yellow Head pass was preferentially selected, and it was found that it was possible to reach the coast by the course and outlet of the rivers Thompson and Fraser, the line terminating at an excellent harbor on Burrard inlet. It was ascertained that portions of the route through the Rocky mountain region would be expensive, but that the engineering features which govern the cost of working a railway and transporting goods promised to be much more favorable on the Canadian line than on the American route.

Ten routes have been opened for consideration by Mr. Sandford Fleming and his assistants. These routes terminate on the coast of the main land at seven distinct harbors, but they all converge on Yellow Head Pass. The line has been "located" with sufficient accuracy to admit of the construction of an overland telegraph. Upwards of 1,000 men have been employed in the surveys directed by Mr. Fleming, and the routes explored amount in the aggregate to nearly 46,000 miles. Of this aggregate, eleven thousand five hundred miles were laboriously measured yard by yard, through mountain, prairie, and forest, with spirit level, chain, and the usual appliances. Mr. Fleming is obliged to admit that, although several routes are available from the Rocky mountains to the Pacific coast, it cannot be claimed for any one of them that it is free from constructive difficulties.

PROGRESS ON THE BROOKLYN BRIDGE.—The work of laying two of the four great cables of the Brooklyn bridge is now in progress. The steel billets out of which the wire of these cables is manufactured, says the *American Manufacturer*, are from the works of Messrs. Anderson & Passavant, of Pittsburg, and, as delivered, are drawn to a fourth inch in thickness. The work of preparing the wire from these billets is done at a manufactory in Brooklyn. Before being galvanized this wire measures 165-1000 of an inch in diameter. Before being sent to the bridge it is galvanized and receives two coats of oil, increasing the diameter to from 168-1000 to 173-1000, weighing in coils of from 800 to 1,200 feet, not less than 60 pounds. On the anchorage the wire receives another coat of oil, and is wound on to drums in lengths of about 10 miles, the wires being spliced, and from them is paid out and brought to the New York anchorage by means of the carriers. The cables, of which there will be four, when complete will consist of 19 strands of 330 wires each. It is thought that one strand for each cable can be completed in one month, at which rate it will take nineteen months to finish the cables. The cables will measure about 15½ inches in diameter, and weigh some 800 tons each.

IMPROVEMENTS IN THE OHIO RIVER.—It appears that measures are being taken by the proper officials to secure to the United States government a title to needful grounds on the river, for the construction of an experimental dam at the head of Davis island. The *American Manufacturer* says this is intended to test the suitability and efficiency of the proposed lock and dam system for the improvement of the navigation of the Ohio river. Such a dam will not only afford the required test, but will subserve the very important end of raising the water in our harbor, so as to facilitate, at all times, navigable communication between its various parts, and present to the fleet transporters water-room and depth for making up their tows, and having them always in readiness to depart on the flood tides. At these periods a channel four hundred feet in breadth will be opened in the dam, giving ample room for the easy descent of the tow-boats with their long and wide-spaced convoys.

WHAT IS AN ENGINEER?—At the last meeting of the English Society of Engineers the President, Mr. Vaughn Pendred, stated in his address that in the highest sense of the term an engineer is a man who cannot only invent or de-

wise but execute; in a subsidiary sense every man who can construct is an engineer. Such an admirable definition, says the *Mining Journal*, can offend no one, for it will include not only the Telfords, but the Stevensons, and the builders of such elegant bridges as that which recently doubled up in Germany, but also the entire manufacturing population of the world, from Sir Joseph Whitworth to the itinerant tinker; it will account, too, for the freedom with which the title of engineer is assumed by men of all classes and possessing various degrees of knowledge, and should have the effect of largely increasing the number of members of that useful society of which Mr. Pendred is the able representative. Admitting that every man who can construct is an engineer, there will be less difficulty in accepting the President's gratifying assurance that the whole army of engineers, civil and mechanical, has operated from the earliest ages to the present moment in the achievement of a great work, no less a work than the civilization of mankind, and that he is enunciating a great truth in declaring that engineers have done more to raise men to the high level which they now occupy than even the philosopher or the statesman; that engineers are the great civilizers of mankind, and that nearly all that is good, or pleasant, or worth having in modern life—happy engineers—results from their labors.

CROOKED RAILWAYS.—We read of something abroad which has been hinted at in our own country. The crooked nature of the railway from Galatz westward parallel with the Danube is a peculiarity which there is nothing in the surface of the land to account for. A correspondent of *Le Temps* explains that in following out on the map the capricious zigzags which the principal Roumanian railway describes, a circumstance which becomes more complicated in the eyes of the traveler by reason of a number of curves of a utility more than questionable, one asks himself the reason of this extraordinary antipathy for straight lines, which has placed under the cannon of the Turks an important point in the line of communication so valuable, since it would have been both more direct and safer to have one line run ten good leagues distance in the interior. Here is the singular explanation they give, such as it is. The Roumanian railway was undertaken by Strousberg. It was a memorable impudence, to speak with prudence. One of the stipulations of the contract was that there should be a certain subvention per mile, and this was accorded before the line was laid out. The contractor accordingly lengthened his line with curves to the utmost possible extent.

GRANITE RAILWAYS.—A French engineer has proposed to establish tramways with granite tracks in lieu of rails, in Finisterre. He is of opinion that this system is far preferable to the ordinary railroads. There already exists a vast network of what are in truth tramways with granite rails, worked by horse traction, in northern Italy. In the streets of the principal towns, and sometimes on the roads, tracks of granite are laid in the highways. The surface of these tracks being flat and perfectly smooth, the wheels of the vehicles glide over them with the least possible friction. The conductor of each vehicle takes care so to guide it that the wheels always remain on the granite. The author of the project maintains that there is nothing to prevent the granite lines from being used by carriages driven by steam power, in like manner as though drawn by horses. At the same time it is not proposed to adopt the train system on granite tracks; each carriage will be provided with its own steam power, will move by itself, and be guided by means of a mechanism specially devised for the purpose.—*Pull Mall Gazette*.

THE INTERIOR SEA IN ALGERIA.—From the recently published report by Rondaire on his mission to the Chotts, between Biskia and the Gulf of Gabes, in North Africa, *apropos* of the project of making an interior sea, the *English Mechanic* learns that some 25,000,000 to 30,000,000 cubic meters of sand would have to be displaced directly. The probable expense is put at 25,000,000 to 30,000,000 francs. The water of the Mediterranean would be depended on to effect the deepening of the trench, to the extent of 110,000,000 cubic meters.

THE WATER ROUTES FROM CHICAGO TO NEW YORK.—Erie canal-men have reduced their charge to four cents per bushel on corn from Buffalo to New York; the lake vessels are carrying from Chicago to Buffalo for two cents, and, adding the elevator charges at the latter place and the insurance, the total cost of sending a bushel of corn from Chicago to New York is now about seven and a half cents, the rate being about 16½ cents per bushel. Last year the canal rate alone was nine cents on corn, which was a large reduction from former charges.

AN EASTERN ENGINEER COMING.—The *Railway Age* announces that Major Lyman Bridges, of Chicago, well known as an engineer and bridge builder of high repute, is about to take a tour of observation through California and several of the Territories, and has kindly consented to favor the *Railway Age* with a series of communications upon railway matters in those regions. Major Bridges's familiarity with railway construction in this country and Europe will make his letters of special interest to readers.

USEFUL INFORMATION.

Poisons in White Rubber.

We have lately alluded to the dangerous qualities in this substance. The subject is worth further description and we quote from the *Manufacturer and Builder* as follows: Rubber is at present largely adulterated so as to make it cheaper. The overshoes and boots made of this material are adulterated with finely-ground burned potter's clay, of which it can stand as much as 65 per cent, without losing its fitness for the purpose. The adulteration is harmless, only the material is not so strong, and the shoes or boots, instead of lasting several seasons, as the old-fashioned little or non-adulterated material, scarcely last one season, as they tear very easily and holes soon wear in them. While the pure rubber is stronger than the best leather, the adulterated rubber is less strong than the worst leather.

Rubber hose and sheet rubber are usually adulterated with soapstone. This gives a lighter color to the material, while the burnt clay adulteration leaves it dark-colored, which is preferred for shoes. But some adulterations are hurtful, being poisonous in their nature. Such is the adulteration with zinc-white, which makes the rubber very light-colored, and is used in the rubber for nursing-bottles and children's toys. The effects of zinc poisoning on the system are scarcely less alarming than lead poisoning. Some time ago a little child in Pennsylvania died from chewing a paper collar, which, like many paper collars, was prepared with zinc-white; and cases are now on record where children have become sick from keeping rubber toys in their mouths. So many cases of zinc poisoning from the white nipples of nursing-bottles have already occurred, that the use of zinc in them has been mostly abandoned. These rubber nipples, or dolls, when laid in vinegar, become covered with an incrustation of zinc acetate. In one case, in 0.73 gram of a doll 0.45 gram of zinc oxide was found, (over 60 per cent.) In subjecting such rubber objects to a red heat, 62 per cent. of ashes remained, while the ashes were yellow while hot and became white on cooling, which is the characteristic behavior of zinc oxide, called zinc-white. In another case, in a doll warranted harmless, 58 per cent. of ashes was obtained, mostly all zinc oxide.

Several chemical journals are now calling attention to these facts, and it is to be hoped that it will effect an amelioration in the consciences of the manufacturers.

TO DISCOVER COTTON IN WOOLEN FABRICS. The *Journal of Chemistry* says: Ravel out the suspected cotton fiber from the wool and apply flame. The cotton will burn with a flash, the wool will curl up, carbonize, and emit a burned, disagreeable smell. Even to the naked eye the cotton is noticeably different from the filaments of wool, and under the microscope this difference comes out strongly. The cotton is a flattened, more or less twisted band, having a very striking resemblance to hair, which, in reality, it is; since, in the condition of elongated cells, it lines the inner surface of the pod. The wool may be recognized at once by the zigzag transverse markings on its fibers. The surface of wool is covered with these furrowed and twisted fine cross lines, of which there are 2,000 to 4,000 in an inch. On this structure depends its felting property. Finally, a simple and very striking chemical test may be applied. The mixed goods are unraveled, a little of the cotton fiber put into one dish and the wool into another, and a drop of strong nitric acid added. The cotton will be little or not at all affected; the wool, on the contrary, will be changed to a bright yellow. The color is due to the development of a picrate.

LIQUID WATERPROOF SHOE POLISH.—The following is said to be a good formula for the purpose: Dissolve 1 oz. of india rubber in 1 pint of oil of turpentine by the aid of a water bath, preventing loss; dissolve 15 ozs. of pure beeswax, 2 ozs. of Burgundy pitch, and 1 oz. of gum olibanum in 4 pints of oil of turpentine; then rub 2 ozs. of the finest lamp-black with 1 pint of oil of turpentine to a smooth mixture, and mix the three solutions. Add now ½ pint of copal varnish and afterwards 5 pints of lime water in quantities of 4 ozs. at a time, stirring after each addition, and continuing the stirring after the whole of it is added for some time afterwards. The mixture must always be well stirred up before any is taken out for use.

COPPERING IRON AND STEEL, DRY WAY.—In cases where it is desired to give a stout coating of copper, brass or bronze to wrought or cast-iron goods, and a uniform thickness is not essential, a sufficient quantity of the metal is set to melt in a crucible. Its upper surface receives a layer of Gaudoin's flux, a mixture of cryolite and phosphoric acid, and the article, heated to the temperature of the bath, is placed in it. If the article is heavy, it will be well to heat it gradually and thoroughly, both to avoid unequal expansion and to obviate the danger of the coating peeling off in consequence of unequal contraction.

KETTLES.—The old notion that a three-legged tea-kettle boils soonest, is correct, because the legs conduct heat more rapidly than the plain surface alone.

Durability of Timber.

The durability of timber is almost incredible. The following are a few examples for illustration, selected for the *Railway Age*, from various sources, and vouched for by scientific men.

The piles of a bridge built by Trajan, after having been driven more than 1,600 years, were found to be petrified four inches, the rest of the wood being in its ordinary condition.

The elm piles under the piers of London bridge have been in use more than 700 years, and are not yet materially decayed.

Beneath the foundation of Savoy place, London, oak, elm, beech and chestnut piles and planks were found in a state of perfect preservation, after having been there for 650 years.

While taking down the old walls of Tunbridge castle, Kent, there was found in the middle of a thick stone wall a timber curb, which had been enclosed for 700 years.

Some timber of an old bridge was discovered while digging for the foundations of a house at Ditton park, Windsor, which ancient records incline us to believe were placed there prior to the year 1396.

The durability of timber out of ground is even greater still. The roof of the basilica of St. Paul, at Rome, was framed in the year 816, and now, after more than 1,000 years, it is still sound, and the original cypress-wood doors of the same building, after being in use more than 600 years, were, when replaced by others of brass, perfectly free from rot or decay, the wood retaining its original odor. The timber dome of St. Mark, at Venice, is still good, though more than 850 years old. The roof of the Jacobin convent, at Paris, which is of fir, was executed more than 450 years ago.

The age of our country's settlement does not enable us to refer to examples of like antiquity; but no good reason appears to exist why timber may not be as durable in America as in Europe. Many old white-pine cornices here exist, which, having been kept properly painted, have been exposed to the storms of more than 150 years. The wood is still sound, and the arisies are as good as when they were made; while freestone, in the same neighborhood, has decayed badly in less than 50 years.

THE COST OF FEEDING PARIS.—The cost of the daily dinner of the Parisians has been calculated by one of the French papers as follows: Bread, about 275,000 francs; wine, 250,000 francs; beer and cider, 15,000 francs; water, for cooking and drinking purposes, 6,500 francs; sausages, pig's feet, etc., 8,000 francs; pates and crabs, 5,000 francs; oysters, 4,500 francs; eggs, 17,500 francs; butter, 11,000 francs; beef, 230,000 francs; veal, 20,000 francs; mutton, 35,000 francs; pork, 33,000 francs; poultry, 24,000 francs; fresh water fish, 2,000 francs; sea fish, 16,000 francs; vegetables, 200,000 francs; entremets, fine and ordinary pastry, 50,000 francs; cheese, 4,000 francs; fruits and preserves, 12,000 francs; brandy, liqueurs, etc., 50,000 francs. This gives a total of 1,268,500 francs, or about \$255,000, with the addition of 5,000 francs, estimated cost of toothpicks, making altogether an average cost of 25 cents per head as the daily cost of the nourishment imbibed by the Parisians.

PRIMING FOR VARNISH.—Mr. W. R. Lake has patented, in England, an invention for preparing wood for varnishing, which consists of a mixture of "finely powdered flint, quartz or felspar, which are non-absorbents of moisture, is mixed with a suitable liquid, as oil or varnish, colored and applied to the wood by rubbing into its pores with a cloth pad."

GOOD HEALTH.

Do Not Check Perspiration.

Nearly every one knows it is dangerous to check perspiration quickly, and yet many forget to practice the truth they know. The weather has been unusually hot, and the heat may return. Let the following be a hint for behavior. *Hall's Journal* says checked perspiration is the fruitful cause of sickness, disease and death to multitudes every year. If a tea-kettle of water is boiling on the fire, the steam is seen issuing from the spout, carrying the extra heat away with it, but if the lid be fastened down and the spout be plugged, a destructive explosion follows in a very short time.

Heat is constantly generated within the human body, by the chemical disorganization, the combustion, of the food we eat. There are 7,000,000 of tubes or pores on the surface of the body, which in health are constantly open, conveying from the system by what is called insensible perspiration this internal heat, which, having answered its purpose, is passed off like the jets of steam which are thrown from the escape-pipe, in puffs, of any ordinary steam engine; but this insensible perspiration carries with it, in a dissolved form, very much of the waste matter of the system, to the extent of a pound or two or more every 24 hours. It must be apparent, then, that if the pores of the skin are closed, if the multitude of valves, which are placed over the whole surface of the human body, are shut down, great harm results. The great practical lesson which we wish to impress upon the mind of the reader is this:

When you are perspiring freely, keep in motion until you get to a good fire, or to some place where you are perfectly sheltered from any draft of air whatever.

Cooling off suddenly when heated sends many of our youth to an early tomb. It is often a matter of surprise that so many farmers' boys and girls die of consumption. It is thought that abundant exercise in the open air is directly opposed to that disease. So it is; but judgment and knowledge of the laws of health are essential to the preservation of health under any circumstances. When over-heated cool off slowly; never in a strong draft of air. Gentle fanning, especially if the face is wet with cold water, will soon produce a delightful coolness, which leaves no disagreeable results.

Pure Milk for Infants.

The ills which the innocents have suffered through the drinking of impure milk form one of the most startling chapters of modern hygienic literature. It is wise when we know the evil exists to guard against its coming to our loved ones. Prof. James Law, of Cornell University, writes on the subject to the *New York Tribune* many useful suggestions:

The milk must be obtained from a sound, healthy cow, as it is unquestionably tainted in some cases before it leaves the udder.

Few people have any idea of the perfect cleanliness necessary to the preservation of milk. An ordinary washing with water, though uncomfortable for the hands, or even with soapuds, is utterly insufficient. There should first be the thorough cleansing of the dish, and then a rinsing with water at a boiling temperature, which must be poured out, and the vessel dried by simply inverting it over a drawer or table, but without the possibility of contact of its interior with any solid body. If dried with a towel, or if hand or finger, or, indeed, any solid body, is brought in contact with its interior after it has been scalded, organic matter, bacteria, and other germs may be deposited which will precipitate decomposition in the milk placed in it. But if the vessel is first carefully cleansed from all organic matter that may cover and protect such germs, then rinsed out with boiling water, set aside to drip, and finally filled with milk, having had nothing touch its inner surface from the contact with the boiling water until now, such vessel will not communicate to the milk any decomposing element. Every vessel, from the pail which receives the milk as drawn from the udder, to the bottle from which the baby sucks its supply, must be treated in the same way. In the case of babies' bottles, it is best to keep two, to be used alternately, the one with its tubes and the teat being thoroughly washed with soda, and then immersed in a dish of pure water until wanted, when it may be taken out and scalded before the milk is put in.

As regards temperature and antiferments. None of the chemical antiseptics are entirely unobjectionable. Boiling of the milk renders it more indigestible, and tends to produce costiveness. The only unobjectionable method is to secure perfect purity of dishes and milk, and to keep the latter at a low temperature. A sufficient degree of cold may be obtained in any house, with no expense and little trouble, by simply enveloping the dish in which the milk is kept in a wet towel, from which evaporation will go on constantly. A tin can with cover, enveloped in a wet cloth, will not only be kept very cold, but will be protected against the access of germs which would superinduce decay. I have in this way kept milk for the baby, perfectly sweet and good, in the warm rooms of a boarding house, in midsummer, while the landlord failed to keep the same milk sweet for half the time, though in a cellar and abundantly surrounded with ice. The great superiority of the wet-cloth preservation consists in its filtration from the air of all germs of decomposition which would otherwise gain access to the milk.

EAU DE COLOGNE AS AN ANÆSTHETIC.—At a recent meeting of the Nice Society of Medicine, Dr. Hughes presented some observations upon the anæsthetic influence of Eau de Cologne, which he had recently noticed. In one instance, that of a young lady afflicted with tubercular consumption, and with whom injections of morphine and the use of chloral had failed to produce the desired repose, a friend suggested a trial of Eau de Cologne, which she had already used with success in similar circumstances on some twenty different occasions. An immediate experiment was made, by placing a handkerchief well moistened with cologne under the nostrils of the invalid, who, in the space of seven minutes, sank into a profound slumber. The same experiment was repeated in other cases, with excellent results.

FORCE-GIVING FOOD IN SUMMER.—Brown bread, oatmeal and fruits are all force-giving, but to a less extent than fats, yet sufficiently so for the requirements of the season, and those persons much who have very muscular work to do may use more freely force-giving foods in hot weather than those whose labor is sedentary and light. From experiments which we have seen tried, over and over again, however, we are satisfied that even farmers, in the hottest days of summer, who are obliged to work in the harvest field can do more work, suffer less with heat, and incur less risk of sunstroke by following the rules we have laid down, than by using a highly carbonized diet of oils and fats.—*Dr. Holbrook*.

Four insertions are rated in a month.
SUBSCRIPTION IN ADVANCE—Postage paid—one year, \$4; six months, \$2.25; three months, \$1.25. Remittances by registered letters or P. O. orders at our risk.

WRITE for the MINING AND SCIENTIFIC PRESS. We invite not only professional men, but practical miners and mechanics to contribute to our columns. All communications will be kindly treated. Authors, as well as readers, will be benefited by corresponding.

ADDRESS all letters to the firm, and not to individual members, or others, who may at any time be absent.

Our latest forms go to press on Thursday evening.

SAN FRANCISCO:

Saturday Morning, June 23, 1877.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Academy of Sciences; The Hydraulic Mining Season; Improved Steam Engine Cut-off, 393. Alluvial Mining; The Black Hills; The Coming Industrial Exhibition, 400. The Monnier Process at the Providence Mine; Notices of Recent Patents, 401. Another Indian Uprising; The Early History of the Eastern Slope, 404. Items of Interest from the Mines, 405.

ILLUSTRATIONS.—Fish's Variable Cut-off, 393. The Chinese Tea Plant, 398. Ground Plan of the Providence Reduction Works, 401.

CORRESPONDENCE.—The Water Supply of Philadelphia; Cinnabar Deposits; Growth of Gold, 394.

MECHANICAL PROGRESS.—System and Cleanliness in Machine Shops; Weight of a Life in Coal; Better Times in New York; Important Improvement in Submarine Telegraphy; Flux for Welding Steel; Car Heating; New Horse-shoe, 395.

SCIENTIFIC PROGRESS.—Transparent Gold; How to Prepare Botanical Specimens; Glacial Action; Heat; In Africa; Woodruff Scientific Expedition; Jurassic Fauna, 395.

MINING STOCK MARKET.—Sales at the San Francisco, Pacific and California Stock Boards; Notices of Assessments, Meetings and Dividends; Review of the Stock Market for the Week, 396.

MINING SUMMARY from the various counties in California, Nevada, Utah, Oregon, Montana and Arizona, 397-404.

GENERAL NEWS ITEMS on page 405 and other pages.

THE ENGINEER.—The Canadian Pacific Railway; Progress on the Brooklyn Bridge; Improvements in the Ohio River; What is an Engineer? Crooked Railways; Granite Railways; The Interior Sea in Algeria; The Water Routes from Chicago to New York; An Eastern Engineer Coming, 398.

USEFUL INFORMATION.—Poisons in White Rubber; To Discover Cotton in Woolen Fabrics; Liquid Waterproof Shoe Polish; Coppering Iron and Steel, Dry Way; Kettles; Durability of Timber; The Cost of Feeding Paris Priming for Varnish, 399.

GOOD HEALTH.—Do Not Check Perspiration; Pure Milk for Infants; Eau de Cologne as an Anesthetic; Force-Giving Food in Summer, 399.

MISCELLANEOUS.—Gravel Mining; Resting Springs District; Granite, 394. The Tea Plant; The Gum Arabic Tree; Singular Formations, 398. San Andrea Mines; Bullionville; Deep Mining Shafts in Europe; Hydraulic Machinery at the Uphir Mine; Lake Superior Ship Canal; Cubical Contents of a Ton; Through the Pyreness; Arizona as a Mining Country; Utah Smelters, 402.

The Week.

The principal feature of the week in connection with the mining interests, has been the very sharp advance in mining stocks and the equally sharp decline which followed. This little spurt has been quite disastrous to small buyers, who, after a couple of days' rise, went in only in time to have their margins cleaned out in the fall. This fluctuating in prices so suddenly only proves that something more than mere rumor is needed to sustain the market at present.

The various hydraulic mines throughout California are beginning to think of final clean-ups for the season, as the water is giving out pretty fast. The remainder of the summer must be passed in preparing for the fall rains and getting the claims in order. Of course many mines are still washing, but this will not continue much longer. There is nothing special to chronicle in connection with the quartz-mining interest, other than what we have mentioned in our "Mining Summary." In a general way, the most exciting news of the week is that of the uprising of the Indians and massacre of settlers in Idaho. In the first conflict with the troops the Indians have had the best of it. If the dispatches state the truth our troops are not to be praised for bravery, as they broke ranks and retreated in spite of all the officers could do to prevent them. Captain Theller and Captain Trumble were both killed, as were a number of troops. The Indians are well armed. The War Department seems to be taking unusually active measures for the concentration of troops, and will doubtless close this "war" quicker than those carried on against the Modocs or the Apaches.

Alluvial Mining.

The deposits of auriferous gravel in the State of California are even more immense than was supposed a few years ago, and they are now being mined in every direction. New deposits are being found and opened, and new channels discovered. In another column will be found the details of the latest discovery of this kind, in Nevada county. Not content, however, with mining the beds of the ancient pliocene rivers, our progressive miners are devising all sorts of plans to get the gold out of the present river beds in places where the flow of water prevents their working the bed by wingdam and flume. True, this year, owing to the dryness of last winter and the consequent small flow of water, the upper parts of some of the big rivers are now being worked in this way; but means are also being arranged to get out the gold where the flow of water is heavy and continuous.

One way now being tried is to sink shafts on the banks and drift under the river bed and get the gravel out that way. The Yuba River mine, worked in this way, struck pretty rich gravel a few weeks since and the projectors think the enterprise is success, and they will have many followers. A similar scheme, however, tried in the Feather river last year has been abandoned.

Another method now being tried is with the "mining machine," at work in the Feather river, near Oroville. This machine—a sort of boat—takes up the debris from the bottom of the river and discharges it into a flume. It is claimed that this machine is a perfect success, and others are now being built and contracted for. The machines cost about \$10,000 each, and while they are highly praised by one of the local papers where they are at work, another one condemns them.

Still another plan for working river beds, only applicable, however, to particular localities of favorable geographical features, is being tried on the South Yuba river. In this as in other rivers in this State, vast amounts of rich gravel and tailings pass down every year, from the gravel claims discharging into it, so that the bottom is very rich. The Nevada *Gazette* describes a method of working the bed, without having to put up an expensive flume, which is liable to be washed away at any time. A point has been selected at the old Hoyt road crossing, where the river makes a horseshoe bend around a projecting point, and here it is proposed to construct a tunnel large enough to take the entire stream at all moderate stages of water. This tunnel will be flumed and paved in the usual way, and also have undercurrents at its lower end. By having proper head gates at the entrance of the tunnel the flume is made perfectly secure from damages or loss by high water, and the flow through it can be regulated to suit the capacity of the flume at all times. The tunnel will be one thousand feet in length, twelve feet wide and eight feet high, with a grade of three inches to the box. The location has been carefully planned and surveyed, so as to secure every advantage which a work of such importance, and requiring such a large outlay of capital, should have. The head of the tunnel will tap the river eight feet below its bed, while its mouth will be above the highest water mark. The proprietors of this enterprise have gone quietly to work without display, buildings have been erected, materials hauled upon the ground, and the tunnel is now progressing through hard granite, at the rate of five feet a week, with one shift at work. In a short time three shifts will be at work and it is expected that at least fifteen feet per week will be made until the work is completed.

COAL AT PALISADE.—The recently discovered coal mine at Palisade is developing into a fine vein. Messrs. Ferguson & Young are busily engaged sinking a shaft and have attained a depth of 20 feet. The vein grows larger and better-defined as developments are made, and the company are very sanguine of the future importance of the mine. Quite a quantity of the article has been brought to Palisade and submitted to various tests, all of which have proved that it is of a superior quality. Johnny Bell tried it in his engine and claims it is better than the Rocky mountain product. Prof. Price examined a specimen and pronounced it a first-class article of coal. The benefits that will accrue to Palisade in the event that it proves to be a permanent and large deposit can hardly be estimated. The great want of the Central Pacific railroad is coal, as at present they are at the mercy of the Union Pacific and draw their supplies from that source. Any discovery that would render them independent would immediately command a large price, and we have no doubt but they are watching the developments at Palisade, ready to become purchasers at the right time.—*Eureka Sentinel*.

AT FOREST CITY, Rev. W. P. Koutz will deliver the 4th of July oration. A handsomely executed poster, from the office of the Downieville *Messenger*, gives an interesting programme of exercises, which will doubtless be enthusiastically carried out, in that patriotic altitude of the high Sierras.

The Black Hills.

We had a conversation this week with Mr. Murry Dunham, of Oakland, who has just returned from the Black hills, and elicited from him some interesting facts concerning that region. He says the region is one about which two entirely different accounts may be given and yet both be true, which is probably the reason why so many contradictory stories are current. One thing, however, admits of no contradiction, which is, that the place is the worst one for a poor man that can be conceived. If he depends on his labor alone he cannot possibly make a living. Any man is foolish to go there thinking that he will be able to get a living by working for other people in case he does not strike a rich claim. There are lots of men there now willing and glad to get a chance to work for their board. Provisions and tools are very high. No credit whatever is given. The richest man in the country could not get trusted for 10 cents' worth of grub. Nothing but hard cash will satisfy the people in there, most of whom, who have anything to sell, are Eastern men who have had no experience in mining camps and are the "closest" people that ever lived.

All the placers except Deadwood and a very small portion of Whitewood gulch are very deep; these gulches are deep, too, but have plenty of fall. The water is very scarce. French creek has only between 10 inches and a foot fall to the mile, and the diggings are from 25 to 40 feet deep. If a man had means to drift out the gravel he might make it pay, but it would take a good deal of money, pumps, etc. They have never found anything very rich in French creek, although the original town of the hills was started there, on rim-rock prospects. The streams there do not seem to rise in the hills as they do here at all. The hills are broken and stand alone. The streams run through the plains toward the Cheyenne and other large streams that eventually empty into the Missouri.

As to quartz, there is plenty of it in the hills, and nearly every man you meet has a rich "ledge," but wants to sell it. Mr. Dunham does not think, however, that there is a regular true fissure vein in the country. The quartz is simply in deposits which seem to extend over the whole region. One can sink almost anywhere from two to five feet and he is sure to find it, more or less rich. If the prospectors do not find free gold in the quartz they consider it of no value, and try again. The probability is that they will find better claims than those already located when they begin to examine the quartz more carefully. There are seven quartz mills in the hills and one arastra; Mr. Dunham met on the road the machinery for 15 more mills, which will be put up immediately.

In most of any of the quartz mines two men can get out ore enough to keep a 20-stamp mill running, as the deposits are all surface, so that few miners can find work getting out quartz. They strip off the top dirt and put in a giant powder cartridge so as to break out the rock easily. These quartz deposits seem to be from four to 15 feet deep.

The hills seem to be right down in a pot-hole about 3,000 feet below Cheyenne, and the streams all run through on a level with the plains. Mr. Dunham thinks that Deadwood will fizzle out soon and the town of Troy, formerly Gayville, will be the center of population of the hills. Deadwood, however, has got a pretty good start.

In Mr. Dunham's opinion the Black hills country is the best prospected one he ever saw. There are so many men there with nothing else to do that they keep at it right along, and have gone over every foot of ground where they thought it likely they might find something. They will tell a stranger that if they could only get down to the old channel of French creek and have pumps at work that they could get out any amount of gold. In trying this Mr. Dunham put down a shaft eight and one-half by nine and one-half feet on the rim rock on both sides. Then they went to the center and sunk a shaft 10 by 15 feet, 17½ feet deep, cleaned up the bedrock and never got a color. The papers have told a good many yarns about men making \$40 a day on French creek, in places where they have really not found a color. There are perhaps 300 inches of water running in the bedrock, but none at all on the surface. The gold seems to be all on the rim rock and on the bars and not much at that. They do not really amount to much more than "China diggings."

Castle, Battle and Spring Creeks are all places of great expectations, which Mr. Dunham thinks will never be realized. In Farmer's gulch and Foster's gulch there are some claims that are paying; there they are drifting out the gravel. The famous claim formerly owned by Mr. Wheeler is washed from the surface, but all the others are drifted out and the gravel hoisted. All of this has to be timbered, as there is not gravel enough to hold, and when clay is struck the ground slides. Although there have never been so many people in the hills as supposed, Mr. Dunham thinks that there are more there now than the country can support. There will be a great deal of suffering there this winter, as almost every man you meet is broke, and it is difficult to see how they are going to get away. They can do nothing, even if there were lands to cultivate, as the grasshoppers are seen by the millions every-

where. A good many men have gone to the Big Horn and Yellowstone on prospecting trips. Mr. Dunham says that if the rush continues there will be 5,000 people in the Big Horn region this fall. In the Black hills, within a space of 25 square miles, there have been as many as 40,000 people, so that it has been pretty well prospected. Most of the people were from the East and Colorado. The climate is horrible, with thunder, lightning and rain seemingly all the time. It is colder at Cheyenne, however, than in the hills. Between that town and the hills there are 200 miles of plains where there is no shelter or timber, and in the winter these plains are pretty hard places to cross on foot. It is called 290 miles from Cheyenne to Deadwood, but all those who walk it call the distance the longest kind of 400 miles, so it is pretty hard to get out of the hills after once getting in.

The people are still going in, however, and on the road our informant met between 3,000 and 4,000 Chinamen on their way in. These fellows all get on in the mines some way. They apparently have no work, but are never seen to beg, and must help each other.

The Indians have probably killed a great many more of the prospectors than is supposed, and those traveling in small parties have fared pretty rough. There is many a fellow packing his blankets out who rode in on the stage not long since, but there are many more who cannot get away and have nothing to do while there. The country is a pretty big one for quartz, but a miner with the best sort of a claim might as well have none, unless he has the money to get a mill; the hills will need capital just as other mining localities need it to be developed. The class of people there now, generally have no knowledge of mining, although there are, of course, exceptions to this statement. The country in the hills themselves is heavily timbered, and the timber is very thick where it occurs at all.

Mr. Dunham thinks that the quartz interests of the hills will be very large, but that the placers will never amount to much. The quartz seems a big body all over the hills and some of it is very rich indeed. Free gold is to be found almost everywhere, and everybody owns claims, which, however, are not much use to them in making a living.

The Coming Industrial Exhibition.

We are assured by Mr. Culver, Secretary of the Twelfth Industrial Exhibition under the auspices of the Mechanics' Institute, that the coming fair promises to be the most successful ever held in this city. Already there have been more applications for space than ever before, and the number of exhibitors will be largely in excess of any previous fair. There will be a number of very fine exhibits in different classes which will eclipse former efforts.

The exhibition will open on August 7th, and be continued for one month. The Pavilion will be open for the reception of articles on and after July 16th. The Board of Directors have purchased the large engine which furnished power last year, and will continue to use it for that purpose; of course no charge will be made for power. The engine will be in operation for one week previous to the opening, and exhibitors of machinery will be required to have their machines in running order on that day.

This year premiums are to be awarded for the first degree only, as no second-class premiums will be given. It will be understood that while one class may be considered superior in merit to another class, yet the awards made will be for the best in that class to which the article receiving the award belongs. A copy of the award of the jury, certified to by the proper officers, will, in all cases, be given when demanded, and no fee charged. In cases where cash constitutes the premium, the awards will vary in accordance with the value of the exhibit.

A very good feature, if carried out, will be that of experimental tests and trials with mechanical devices competing for awards. These trials always excite considerable interest, and put the competitors in a position in which they must show true merit, or "take a back seat." As only one premium is given, as stated above, the article in any special class winning the medal will be the best in its class. Therefore, as an advertising proposition alone, it behooves manufacturers and agents to begin to get ready their machinery as soon as possible, so as to have everything in first-class order.

The dull times in business which have been felt lately among us have not been at all detrimental to the interests of the coming exhibition; in fact, the reverse has been the case. In many instances previously people have failed to exhibit, giving as an excuse that they did not have the time to spare to arrange any display. Of late, however, business generally has been so dull that there has been plenty of time for preparation, and as it is known there is always a good attendance of visitors at the fair, those likely to exhibit know they can have no better opportunity of bringing their names and wares before the community. Accordingly a much better and longer display than usual is expected.

Messrs. Dewey & Co. have been awarded the privilege of publishing the *Fair Daily* again this year, and are preparing to get up a first-class paper, devoted to the interests of the Twelfth Industrial Exhibition. The experience of this firm in this particular field warrants the assertion that the *Fair Daily* will as usual be favorably received by exhibitors and visitors.

The Monnier Process at the Providence Mine.

In the MINING AND SCIENTIFIC PRESS of Sept. 4th, 1875, we gave the details of the Monnier process, as applied to copper ores. Since then it has been for some time at work on gold ores, at the Providence mine, in Nevada county, in this State. Our correspondent, Mr. J. W. A. Wright, who is at present in Nevada county in the interest of the PRESS, last week examined this process carefully, and sends us the following notes concerning it, which will be read with interest:

Perhaps no mining enterprise in California is watched with more interest, at present, than that now connected with the well-known Providence quartz and sulphuret mine, on Deer creek, near Nevada City. Experts call it "a new departure" in the mining interests of the Pacific States.

This valuable mine is owned by

Messrs. Walrath & Hunter.

During the last six months they have been preparing for the introduction on this coast of this new method of reducing ores, and for more than a week past their works have been in successful operation. This is the method of reducing refractory ores by roasting and lixiviation, as invented and patented by Alfred Monnier.

Being kindly afforded every facility to investigate this method of extracting the precious metals, so entirely new to our coast, I shall try, by aid of the Professor's explanations, and the accompanying diagram I have made of the ground plan of the works, to give your readers some idea what this method is, how it differs from and what its advantages are over the usual method.

These works are on a steep hillside. Going from A, the highest point, to B, the lowest, you descend from floor to floor some 20 feet. The shaft and hoisting works are about 100 feet to left of point 1. The order of arrangement of cylinder, tanks, arastras, etc., will naturally vary according to the surface to be built upon.

1. Lump ore from mine. 2. Sulphate of soda. 3. Rockbreaker and crusher. 4. Elevators which carry crushed ore and soda to 5. Receptacle of same, whence through 5, they are conducted into 6, revolving cylinder, where the mixture is roasted. 7. Fire-box of cylinder. 8. Lixivating tanks. 9. Reservoir for lixiviating tanks. 10. Reservoir for strong solution. 11. Feeder for evaporator. 12. Evaporator. 13. Crystallizing tank. 14. Arastras. 15. Feeder for copper plate in 16, amalgamating trough. P. Roasted and lixiviating ore ready for arastras. S2. Sulphate of soda taken from crystallizing tank. b, point where iron car receives roasted ore. t, tramway over which car passes to lixiviators.

What are known among miners as "Refractory Ores."

Are those containing a large proportion of metallic sulphurets. The method long in vogue in what are called the "sulphuret works" of our mining regions, is that of chlorination, where common salt, manganese and sulphuric acid are used, and must be purchased for the purpose. The Monnier method for the treatment of metallic sulphurets may be correctly distinguished from the former as the method of sulphatization—a term suggested by Prof. Monnier—since its chemical processes consist in changing into sulphates the sulphurets of different metals contained in the quartzose ore.

The Messrs. Walrath and Hunter have been working their mine about six years, reducing the ore by the common method of chlorination. Their shaft is down something more than 800 feet, with the usual drifts every 100 feet. Some 20 men are now at work in the different drifts and the ore brought up daily is a very fine quality of sulphurets. The chemical compounds it contains, besides the pure silica of the quartz, are sulphurets of silver, copper, iron, zinc, and lead, containing gold, also small quantities of arsenic and antimony. That portion of the ore which is reduced by

The Monnier Method

Is treated as follows:

The crude dry ore in lumps (1) is mixed with sulphate of soda (5) and passed by the shovelful into the rock breaker and thence between Cornish rollers (2). The proportion of the mixture is 20 lbs. soda to 80 lbs. ore. Through one elevator (3) the crushed mixture passes to a wire sieve with 24 holes to the linear inch, i. e., 576 to the square inch. From this sieve the coarser particles return by a chute to the rock breaker, the finer pass through it into a second elevator (3) which conducts the finely pulverized and dry material into a large box (4) whence it is passed regularly through a small chamber of brick and iron into the huge revolving cylinder (6) which is five feet in diameter by 40 feet long.

The Roasting

Is here accomplished. This cylinder is revolved very slowly by water power. Its upper end (a) is raised six inches above the level of the lower end (b). This elevation can be increased, according to the proportion of sulphur in the ore. The cylinder has now been revolving without intermission for a month. Its slow motion causes the roasting mixture to gravitate gradually towards the lowest level, and some 12 hours are required for the crushed sulphurets to pass from the upper to the lower end of this revolving cylinder. It thus contains at one time about seven and one-half tons of the ore, since about

15 tons are reduced by this method every 24 hours.

An intensely heated draft of air passes steadily from the fire-box (7) into the lower end of the cylinder. The mixture is thus heated to a high degree, until at the lower end (b) the ore reaches a dark red heat. This roasting within the cylinder gradually transforms the sulphurets into sulphates and the gold is set free. Chemically this is explained by the sulphur becoming oxidized and

Forming Sulphuric Acid.

This combines with the soda, forming a bisulphate of soda the decomposition of which reduces successfully the sulphurets of iron, etc. A considerable quantity of sulphurous acid is also formed and escapes from the cylinder. The resulting sulphates being soluble in water, you can look with safety from the upper end of the cylinder through its entire length, and see myriads of brilliant scintillations flying to and fro, and falling like so many meteors in miniature. These are caused by the union of sulphur with the oxygen from the atmospheric air. The degree of heat required is maintained by consuming in the fire box half a cord of mountain cedar each 24 hours. The red hot ore passes at b into an iron wheelbarrow, which is trundled by one man along a tramway (t), passing over five huge wooden tanks (8), made on the Monnier plan and partly filled with water at its natural temperature. Here

The Process of Lixiviation

Begins. The man who handles the wheelbarrow takes the roasted ore from it by the shovelful and drops it into any one of the lixiviating tanks. Quite a detonation follows as each shov-

We will now return and see what becomes of The Residue of Insoluble Matter

Left in the lixiviating tanks. It consists of silica, pure gold and sesquioxide of iron, also a small amount of silver with sulphate of lead. When the liquid has been drained from it, it is shoveled out on the platform (P), from which it is passed into the arastras (14). After mixing with water and thorough grinding it runs into the feeders (15)—which act also as reducers of the remaining sulphate of silver—and thence through wooden spigots and troughs into the broad, shallow and long troughs (16), provided from point to point with boxes or catchers of peculiar construction. The bottoms of these troughs and boxes are covered with amalgamated copper plates. Here

The Gold

Is so free it is immediately taken up by the quicksilver, and with the remaining silver is secured in the form of an amalgam, while the residuum, containing oxide of iron, passes outside of the building to a large wooden tank. From that the oxide is collected in a still larger tank, where it settles and is collected and dried. Mixed with oil this

Oxide of Iron

Makes the purest of metallic paints—its natural color reddish brown—and is the very best that can be used on all iron structures. By combining different ingredients with it various colors can be produced. It makes a first-class fire-proof roof paint.

Advantages of Sulphatization

We shall close this description by stating some advantages of sulphatization over chlorination, as is proved at the Providence mine.

GROUND PLAN OF PROVIDENCE REDUCTION WORKS.

elful is thrown in. This is continued until each tank receives its allowance.

By a set of rubber tubes, connection is kept up between the liquid in three of the tanks at a time, thus forming a battery.

When the water in any of the five tanks holds in solution the largest possible amount of sulphates of silver, copper and soda, it is sent by a tube into small tanks filled with cement copper by which the silver is precipitated. Thence the remaining liquid is run into a reservoir (10). This is done in what is called

The Silver Room.

Any weaker solution is passed into another reservoir (9), to be used again in lixiviating, till it attains sufficient strength.

From the reservoir (10), the solution is conducted by a wooden pump and trough into a tank under tank 11. Thence it is raised by a wooden pump into the latter tank, which serves as a feeder for the evaporator (12). This huge evaporator is filled through a wooden trough from tank 11, and the liquid in it is kept at boiling heat by the hot air passed into it from the revolving cylinder and the fire-box.

After a certain time allowed for evaporation, the remaining liquid is passed by rubber syphons from the evaporator into the crystallizing tank (13). This tank now contains only sulphates of copper and soda in solution. As the liquid cools, the sulphate of soda crystallizes and is drawn out by an iron hoe with a long iron handle into a pile (s2), to be used over again to repeat the process *ad infinitum*. The amount lost is scarcely appreciable.

The Copper

In solution is then precipitated by iron. All the round tanks are about the same size, having a capacity of some 700 cubic feet. The five used for lixiviating each hold 25 tons of ore, besides the water needed to dissolve the sulphates of silver, copper and soda.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

QUICKSILVER CONDENSER.—Richard F. Knox, S. F. This condenser is constructed in two parts. The base is cast in one piece and its floor is made in the form of a V, so as to form a middle channel and inclined sides. The base is supported on suitable legs or supports, the length of which are regulated by the pitch of the inclined floor. The upper part of the condenser is made of sheet copper, a metal which will not be affected as readily as iron by the sulphurous acid which accompanies, to a greater or less extent, the quicksilver fumes produced from the raw ores, and which soon destroys iron condensers. Either the iron base or copper upper portion can be removed when necessary and thus produce a considerable saving in the cost of condensers. The thinness of sheet copper also renders the condenser more effective, because it allows the heat to pass off more readily than through a thick iron condenser. The upper part of the condenser is made square and provided with a pan top for holding water, described and claimed in a patent issued to Knox & Osborne, June 14th, 1870. In addition to the pan top for holding water, Mr. Knox makes a well or hollow partition across the condenser near the opening through which the fumes pass out of the chamber, and this partition extends down inside of the chamber to within a short distance of the bottom, so that the fumes must pass under it before they can pass out through the exit opening. This water partition or well communicates with the pan top, so that it is kept filled with water, and as the water in it becomes heated it will rise to the surface of the pan and flow off while the cool water takes its place. This partition enables the inventor to draw off the coolest vapors first, as the vapor in the condenser will settle to the bottom as it becomes reduced in temperature, and will thus first pass under the partition.

BEE-HIVE.—Thos. A. Atkinson, Merced, Merced Co. This invention relates to an improvement in bee-hives, which is more especially useful in preventing the ravages of the bee-moth, and which the inventor calls the moth exterminator or trap. It is a well-known fact that this moth can go wherever the bee can go and a moth-proof bee-hive is an impossibility. They may, however, be trapped and destroyed by the apiarian, and this this invention is designed to effect, by providing artificial hiding places into which the worms will pass at the proper season for the purpose of forming their cocoons and entering the chrysalis state and they may easily be collected and destroyed from these receptacles. The worms which may be concealed in the hive early in the spring are comparatively harmless, but if left to themselves thus will enter the cocoon, emerge as moths and lay thousands of eggs, which are hatched nearly simultaneously, so that before the bee owner is aware of it the bees are destroyed. It is the habit of the worms found in the hives in the early spring to let themselves down from the combs and after reaching the floor to seek cracks and hiding places, both to escape the bees and in order to enter the chrysalis state. It will therefore be seen that when they reach the inclined floor of this hive they will find no place to hide until they reach certain grooves in the entrance blocks. Into these grooves they pass at once and thence down tubes provided for the purpose, into a trough from which they cannot escape, but may be removed and destroyed. This hive is economical and easy of access.

DOOR-LOCK.—C. H. Covell, Stockton. This invention relates to such door-locks as are secured to doors by being fitted in a recess in the side of the door stile, and principally on the inside of the door. These locks as heretofore constructed require the recess to extend from the edge of the door stile, next to the casing, almost entirely across the stile, and this recess must be deep enough to admit the full thickness of the lock so that its outer face will be flush with the side of the stile. Only a narrow thickness of wood was left between the lock and the opposite side of the door, almost cutting the stile in two, and materially weakening the door at that point. And, again, the screws which fastened the lock in the recess were screwed into this narrow thickness of wood, which furnished a slight hold, so that the constant jamming to which the lock was subjected soon rendered it useless. This invention provides such a construction of the lock, that a portion of the wood next to the casing is left to its full thickness, and the screws which fasten the lock in place are screwed into the stile where it has the full thickness of the wood to enter. Other improvements also provided relating to a keyhole guard.

ENGINE VALVES.—Eugene O'Neill, San Francisco. The invention relates to certain improvement, in valves for engines and pumps, and it consists in a novel construction of valve having upper and lower seats in pairs and provided with inner and outer steam and water passages for each pair of seats, so that by a small lift of the valve a large area for the admission of steam or water is exposed,

The engineers who made geological explorations and soundings for the submarine tunnel between France and England, report that the tunnel is perfectly practicable, as there is a continuous bed of chalk between the two shores.

San Andreas Mines.

Within a circle of a few miles of this place are some quartz veins which we firmly believe within the near future will develop into paying properties. The Thorn mine, if it were located in Arizona or some other distant section, would be eagerly gobbled up by capitalists and with good reason, as it presents all the evidences of a rich lead. All that is needed, judging from the prospects is the expenditure of capital to make it a profitable investment. The Thorpe mine always paid for working it, and the only bar to its proving a bonanza was that the proprietor being possessed of but small means was unable to put proper machinery on it, and the abundance of water drove him out. Several thousand dollars have been gouged out of the Comet lead near town, and there is little doubt that a proper mode of working these leads—as well as a number of others, such as Gottschalk's mine, the Portuguese claim, the Jackson claim, all situated near this place, and all carrying free gold in a well defined ledge—would prove remunerative. The two investments which capitalists have made in quartz in this immediate vicinity have been subject to influences which were not calculated to make any mine pay. In one case they took as Superintendent a kid-gloved miner, and after expending considerable money in a stylish way gave up the mine without having really tested its merits at all. This was the Hudson gold mining company, limited—certainly very limited if a knowledge of the principles of quartz mining is referred to. Then another company, "The Everlasting," composed of men who ought to have been possessed of some sense, hired a lumberman—or rather a man who was known as a good hand in a lumber yard—to superintend their investment. It didn't pay; singular, but true, the mine *must* have been worthless. We assert that the prospects of a half dozen leads in this vicinity would justify a company in buying them, and with the aid of a practical, working miner as Superintendent—one who knows the difference between the hanging and foot wall and can tell when men have done a day's work—reaping the reward which the investment of a comparatively small amount of money and as much common sense will surely give.—*Calaveras Citizen.*

Bullionville.

Being among the picnickers on Thursday, on their trip to Bullionville, we took occasion of visiting the Raymond & Ely mill, now in charge of John Cahill. We found that the 18 pans were running day and night to their full capacity on tailings, the eight settlers also being busily employed. Amalgam was being turned out in pretty large quantities, the retorts being made ready to convert it into bullion. The tailings are being worked now to much better advantage than they have heretofore been, and the daily manipulation of them will make the process of working come easier as they are handled and tested. The battery of the mill is now being fixed ready to start crushing ore. Ore is accumulating at the mine and will be sent down pretty rapidly when the battery gets to work.

Near the Raymond & Ely mill Hugh White has his concentrating works concentrating tailings from the Magnet mill. He is at present only able to work a few hands, owing to the Raymond & Ely mill being unable to pump a sufficient amount of water, having to use so much for the mill. To remedy this defect Mr. White has sent to Salt Lake city for a pump, by means of which he will be enabled to secure a large supply of water. The pump is expected to arrive there this evening. The furnace is at a stand still and it is not known when it will start to work, although it is expected daily.

The business portion of Bullionville looks much better since our last visit to that burg, and the business men are not now complaining.—*Pioche Record.*

DEEP MINING SHAFTS IN EUROPE.—Twenty years ago the deepest mining shaft in the world reached only about 2,000 feet below the surface. The very deepest, we believe, was a metalliferous mine in Hanover, which has been carried down to the depth of 2,290 feet. The deepest perpendicular shaft to-day is the Adalbert shaft in a silver-lead mine in Przibram, in Bohemia, which has reached a depth of 3,280 feet. The attainment of that depth was made the occasion of a three-days' festival, and still further noticed by the striking off of a large number of commemorative silver medals of the value of a florin each. There is no record of the beginning of work on this mine, although its written history goes back to 1527. Quite recently an elegant commemorative volume has been written and printed, which is most interesting to those who have a taste for either the actualities or antiquities of mining industry. There are two other localities, however, where a greater depth has been reached than at the Adalbert shaft, but not in a perpendicular line. These are: first, the Rocksalt bore-hole, near Spereberg, not far from Berlin, which, a few years ago, had been bored to a depth of 4,175 feet; second, the coal mine of Viéville, in Belgium, where the miners, by shaft sinking, together with boring, have reached a depth of 3,542 feet. Turning from these two mines, no shaft, in unbroken, perpendicular line, has as yet exceeded the depth of 3,280 feet.

Hydraulic Machinery at the Ophir Mine.

In a recent article the Gold Hill *News* says: The Ophir has the finest incline machinery on the lode, and probably in the world. It consists of a double-cylinder engine of 500-horse power, each cylinder working by a double-gear attachment to an end of the conical reel, upon which in a continuous groove runs the round, tapering, steel-wire cable which descends into the depths. This cable is 3,600 feet in length, two inches in diameter at the larger end and one and three-fourths at the smaller, and weighs 21,850 pounds, and cost \$6,700.

The engine is driven by an extra set of boilers, and is so arranged that either one of the cylinders can be used separately. The convenience of this has been demonstrated. The engineer on duty recently found that, for some reason, the throttle-valve of one of the cylinders would not work, and the engine could not be stopped. It was a moment of awful peril. The giraffe was fast approaching the head of the incline, and in a moment more would be run crashing into the sheaves, carrying death at least to the tender, and no one knew how many more men who might be thereon. Then would come the snapping of the cable as a thread, the fall of the giraffe down the incline, and the dashing to pieces of the miners in the bottom. It was indeed a terrible time, but the engineer, with that readiness of action and presence of mind which never forsakes a competent man when on duty, reversed the engine and thus prevented the disaster. It was then discovered that a coil of wire had in some way found place in the valve, preventing it from closing. While the damage done to the valve is being repaired the other cylinder to the engine is doing the work of both, and trundles the immense conical cylinder with apparently as much ease as both did previously.

Besides the foregoing cylinders to work the incline, the Ophir has two hydraulic engines worked by water from the mine, under a pressure of 400 feet head, which increases the force by 268-horse power. These look like immense battery guns placed for action. They work only in raising the giraffe. In lowering it the water used is, by the weight of the giraffe and cable, pumped back into the tank on the hill, where it is ready to be used again, and so on, over and over. In this way the power for the hydraulics is maintained without cost, subsequent to that of the original construction. These are the engines which are first mentioned as being overhauled preparatory to being put in use.

And now that we are upon the subject of hydraulics, it may not be amiss to mention another power derived from that source, and in constant use at the Ophir. Another hydraulic engine, but of a different kind, has been constructed to raise ore from the level of the works 47 feet, to the top of the ore house erected beside the track of the Virginia and Truckee railroad. Here, again, the motive power costs nothing, as the water is transferred from the engine directly to the boilers, and is none the worse for having once done duty.

The arrangements for protection against fire are perfect. A 10-inch lap-welded main connects with a tank 400 feet above, on the hill, and capable of containing 100,000 gallons of water. Hydrants connect with these mains, and two and one-half inch hose leads all over the exterior of the buildings, while one and one-half inch hose protects the inside. The Ophir buildings cover nearly 40,000 square feet of ground. These, with the machinery they contain, are valued at \$600,000.

LAKE SUPERIOR SHIP CANAL.—The troubles of this unfortunate corporation do not seem to be entirely ended yet. The sale of the canal, its franchises, lands, etc., was made under foreclosure proceedings on the 11th of May. The property, says the *Detroit Post*, was bid in by trustees for about \$377,000 (a sum not sufficient to pay the preferred bonds in full), who proceeded to organize a new company, to whom it was transferred. All parties of record consenting thereto, the sale was confirmed by Judge Brown several days since. At the time of the sale a representative of some of the New York bondholders was on the ground and filed with the master making the sale a written protest against the proceeding, alleging that there was a ring, a conspiracy; that an appeal was pending, that the sale had been insufficiently advertised, and that capitalists stood ready to buy the property in due time at something like its value. This protest was ignored, and this protestant came before Judge Swayne and asked that the confirmation of the sale be set aside. There was much talk about fraud, rings, extraordinary haste in confirming the report of sale, etc. Judge Swayne took the matter under advisement.

CUBICAL CONTENTS OF A TON.—Few persons have any idea as to the amount of coal that can be stowed in a given space; we therefore give an example of the manner in which it may be figured up. A shed or room 15 feet high, 18 feet wide and 300 feet long will hold 200 tons of anthracite coal, and perhaps 10 tons less of Cumberland. Thus 15x18x30=8,100, divided by 40, average cubic contents of a ton of anthracite=202½.

THROUGH THE PYRENEES.—A tunnel through the Pyrenees will complete the railroad communication between France and Spain by January 1st, 1878. It will save twelve hours of diligence riding.

Arizona as a Mining Country.

It is only very recently that Arizona has been admitted to be a mining country. It is true that we have heard for many years stories bounding on the marvelous, about golden bullets, caves studded with chunks of gold, and other wonderful stories of a mineral wealth which, so far as then known, only existed in the realms of romance.

For many years, even after Arizona began to emerge from being a land of savages, and became the home of hardy pioneers, who came at the peril of their lives to settle and civilize this wild region, the first search of the prospector was for gold. No inkling of the great future of Arizona, as a silver mining country, had yet dawned upon the people.

After a few years, however, silver ledges began to be discovered, and in a few years more it began to be discovered that upon the silver mines of Arizona her future greatness would to the greatest extent depend.

For a long time but little development had been made to prove the permanency of the great silver-bearing ledges, but to-day, with the McCrackin down to a depth of over 525 feet, the Hackberry, 430 feet; the Peck, 300 feet; the Silver King, 240; the Lone Star, 250 feet, and the Yellow Jacket over 200 feet, all of these mines actually producing, and producing largely in excess of the expense of working them, we can point to these as mines, not developed, of course, to the same extent as the Comstock mines, but still sufficiently developed to prove this a mining country. No mining man can doubt the permanency of the Hackberry, the McCrackin, the Arnold, the Peck, the Richmond, the Silver Prince, the Black Warrior, and many other ledges which might be named.

The wonderful rich ledges in the Globe district, Humburg district, Peak district and elsewhere, are something new to mining men, so far as the vast number of places in which they are found are concerned, and there are a number of new discoveries in which, like the Zalida, marvelously rich ore is found near the surface, and which it remains for time and muscle to prove.

There is no field for the mining capitalist who wishes to invest in legitimate mining enterprises, at all to be compared to Arizona. The field is larger. From the Wallapai mountains on the north, to the borders of Sonora on the south, from the Castle Dome on the west to the White mountains on the east, is one vast mining district, a net-work of mineral bearing veins.

We would say to the mining men of San Francisco and elsewhere, come and see for yourself. You will find the trip well worth the journey.

Another great opportunity for the investment of capital is in the erection of reduction works, which are ridiculously scarce in Arizona. Ore can be had in any quantity and the miners are willing to pay a liberal price for the reduction of ores.

For any kind of enterprise connected with mining, the opportunity for the investment of capital is better in Arizona than in any other country.—*Arizona Enterprise.*

Utah Smelters.

Sandy, which is some day in the near future destined to become an important mineral center, suffers from the decline in the price of lead quite as seriously as any of the camps. The Flag-staff, however, is running the four stacks at full blast, as usual, and is running through 135 tons of ore every 24 hours, employing 100 men worked on eight hour shifts. Everything is well appointed. The flux is hoisted from the crusher on a tramway by means of a friction gear so arranged that heavy car-loads of lime rock and iron can be sent up to the upper floor without any assistance except one man who loads and dumps the car. After several months' test, Mr. Gist speaks very highly of the Bruckner rotary roaster, and he says he works the Last Chance ores with ease, although very refractory. Since December last the smelter has shipped 350 car-loads of bullion, and the pay roll shows that this concern has dispersed among laborers \$9,000 per month.

The Mingo is now running two stacks, chiefly on ores from Bingham. Mr. Knap intends putting up a single hearth roasting furnace, with a capacity of 10 tons every 24 hours. The bullion is shipped to the Pennsylvania Lead Company, who speak in the highest terms of Utah lead.

The old Telegraph smelter, on Jordan, is still running on ores from the company's mines. The Germania, Morgan and Wasatch, together with the other smelters of the Territory feel the low price in lead. In fact, to be brief, the decline fell like a wet blanket over Zion, her mines and mining men, and they feel sick.—*Salt Lake Tribune.*

One of the buildings at the International exhibition, at Philadelphia, erected and used by the United States Government on the exhibition grounds, having been torn down on Friday last without authority from the Government, the affair will probably lead to difficulties with the Finance Board of the exhibition, as it is charged the building was destroyed by order of that Board. The matter was placed in the hands of the Attorney General, with a request that he proceed against the Board to recover damages; also to have the offenders punished.

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

Really Important.

Dr. Noon's combined Electro-Magnetic Sudatorium
baths cleanse the system from Lead, Arsenical, Mercurial
and other poisons. Will cure Rheumatism, Torpid,
Liver and Chronic Disorders. Our system is the most ef-
fectual in the world, combining with all needed medi-
cines, Hydrogen-Oxygen Inhalations, Electric and Hydro-
pathic treatment, all skillfully used as necessary. Often
cures where others fail, and always in less time.

Dr. Noon has had much special, practical experience in
the treatment of the disorders incidental to mining life.
Consultations free.

Buy the Best.

Before purchasing an American
Watch, examine the different styles
manufactured by the NEW YORK
WATCH COMPANY, at Springfield,
Mass. They are the latest and
best improved manufacture. You
can depend upon them for fine finish,
durability and perfect time. They
are sold at favorable prices—in
fact, no higher than many of the
inferior styles. Examine into the
merits of this Watch before you
buy any other. Our word for it,
you will not regret it.

Newspaper Fileholders.

Dewey's new elastic fileholders (black walnut), size of
the PRESS, Harper's Weekly and Scientific American, for
50 cents. Larger sizes to suit any newspaper, 75
cents. By mail, postpaid, 10 cents extra. Cash with all
orders. Patent allowed. Address, Dewey & Co., Pub-
lishers, San Francisco.

Superior Pianos for the People at Popular Cash Prices.

More than TEN THOU-
SAND prosperous families
on this Coast need Ten Thou-
sand GOLDEN PIANOS to
make TEN THOUSAND
HOMES MORE PLEAS-
ANT AND ATTRACT-
IVE.

Prices of good Pianos
have long been too high.
Our people could not afford
to buy them. But many will
find it not only pleasant but
profitable to purchase

The Brilliant and Durable GOLDEN PIANO

Which we now offer the
readers of this paper

At Greatly Reduced Pop- ular Cash Prices.

We Guarantee them to be
as represented, of superior
tone, finish and durability.

Samples can be seen by
calling at this office. We
keep no expensive sales-
rooms and attendants.

We shall sell none but
superior and desirable instru-
ments, but give our custom-
ers the benefit of prices far
below any before offered on
this side of the Continent.

Prices of the Golden Piano:

The Install- ment Plan Prices.	Our Reduc- ed Cash Price.
The Golden Piano, \$500	\$350
(UPRIGHT—C.)	
The Golden Piano, \$375	\$300
(SQUARE—No. 1.)	
The Golden Piano, \$500	\$350
(SQUARE—No. 2.)	
The Golden Piano, \$600	\$400
(SQUARE—No. 3.)	
The Golden Piano, \$800	\$450
(SQUARE—No. 4.)	

We invite our readers who
wish to look at Pianos for
themselves or friends, for
immediate or future pur-
chase, to call and examine
our samples.

Those who cannot call
will be given further infor-
mation by consulting our
agents or sending to this
office.

Steam Engines & Boilers, NEW AND SECOND-HAND.

One Patent Straw-Burning, Portable En-
gine, (new,) fire box boiler, the best
Portable Engine on the coast; built
by Ransom, Sims & Head, Ipswich,
England.

One Steam Fire Engine, second-hand,
in excellent condition, with 200 feet
leather hose, very cheap, just the thing
for a small town. Button & Blake,
builders, Waterford, N. Y.

One second-hand Stationary Engine, 14x30
inches, link motion, with or without
hoist gear.

One second-hand Stationary Engine, 8x20
inch, with or without hoist gear.

One Upright Boiler, Horizontal Engine
on wheels, Eastern make, 7x12.

One Upright Boiler, Horizontal Engine,
San Francisco make, 6x12.

One small Stationary Engine, 3½x7 inch.
One Steam Boiler, 40 inches diameter, 16
feet long.

One 8x10 Straw-Burning Portable Engine.

One Traction Engine, three wheels, rub-
ber tires, double cylinder, 6x10 inch;
Thompson's patent, D. D. Williamson,
builder, New Jersey.

One Stationary Engine, 10x20, just had a
thorough repair, almost as good as new.

One Stationary Engine, new, 12x24, independ-
ent cut-off.

One 6x12 Engine and Boiler, can be mounted if
required. Very cheap.

Various other second-hand Engines and
Boilers for sale cheap.

ARITHMETIC MADE EASY.

ROPP'S

EASY CALCULATOR

Is a new publication that must prove of incalculable
benefit to Farmers, Mechanics and Business Men. It is
so rapid and original as to startle the most scholarly,
and yet so simple and practical that the most illiterate
in figures can instantaneously become his own account-
ant. It enables thousands to accomplish in a minute
what they could not learn to calculate in many months.

The first part contains an entirely new system of tables,
which show at a glance the exact value of all kinds of
Grain, Stock, Hay, Coal, Lumber, Merchandise, etc.,
from one pound up to a car load, and for any price that
the market is likely to reach; the interest on any sum for
any time at 6, 7, 8 and 10 per cent.; correct measurement
of all kinds of Lumber, Saw Logs, Cisterns, Tanks, Gran-
aries, Bins, Wagon Beds, Corn Cribbs; a Time, Wages
and many other valuable tables.

The second part is a practical arithmetic, and embodies
a simple mechanical principle which enables any one
familiar with the fundamental rules to become a light-
ning calculator; and by which over two-thirds of the fig-
ures and labor required by the ordinary methods, and
fractions with their intricacies, are entirely avoided.

The work is nicely printed on fine tinted paper, is well
and elegantly bound in pocket-book shape and is accom-
panied by a Silicate Slate, Memorandum and Pocket for
papers. It is by far the most complete, comprehensive
and convenient pocket manual ever published.

Price, bound in Fine English Cloth, \$1.00.

Sent direct from the Eastern publisher, postpaid, on
receipt of price, by P. O. order, registered letter, or
received by express. Address

Metallurgy and Ores.

JOHN TAYLOR & CO.,

Importers of and Dealers in

ASSAYERS' MATERIALS,
Chemical Apparatus and Chemicals, Drug-
gists' Glassware and Sundries, etc.

512 & 518 Washington St., San Francisco.

We would call the special attention of Assayers, Chem-
ists, Mining Companies, Milling Companies, Prospectors,
etc., to our large and well adapted stock of

ASSAYERS' MATERIALS

—AND—

Chemical Apparatus,

Having been engaged in furnishing these supplies since
the first discovery of mines on the Pacific Coast.

Our Gold and Silver Tables, showing the value per
ounce Troy at different degrees of fineness, and valuable
tables for computation of assays in grains and grammes,
will be sent free upon application.

JOHN TAYLOR & CO.

THOS. PRICE'S

Assay Office and Chemical
Laboratory,

524 Sacramento St., S. F.

Deposits of bullion received, melted into bars, and re-
turns made in from 24 to 48 hours.

Bullion can be forwarded to this Office from any part of
the interior by Express, and returns made in the same
manner.

Careful Analysis made of Ores, Metals, Soils, Waters,
Industrial Products, Etc. Mines examined and reported
upon. Consultations on Chemical and Metallurgical
questions.

Nevada Metallurgical Works,

21 First Street, 3 doors from Market, S. F.

Ores worked by any process.

Ores sampled.

ASSAYING in all its branches.

Analysis of Ores, Minerals, Waters, etc.

WORKING TESTS MADE.

Plans furnished for the most suitable process
for working Ores.

Special attention paid to Examinations of
Mines; plans and reports furnished.

E. HUHN,

C. A. LUCKHARDT,

Mining Engineers and Metallurgists

LEOPOLD KUH,

(Formerly of the U. S. Branch Mint, S. F.)

Assayer and Metallurgical Chemist,

No. 611 COMMERCIAL STREET,

(Between Montgomery and Kearny.)

SAN FRANCISCO, CAL.

INSTRUCTIONS IN ASSAYING,

Chemical Analysis, Determination of Minerals, and use
of the Blow-pipe.

HENRY G. HANKS

Will receive a few pupils at his new laboratory, No. 617
Montgomery Street, up-stairs. TERMS MODERATE.

STRONG & CO.,

Assayers and Metallurgists,

10 STEVENSON STREET, S. F.

PACIFIC MACHINERY DEPOT.

H. P. GREGORY & CO.

Cor. California & Market Streets, S. F., Cal.

Importers of and Dealers in

MACHINERY of all Descriptions.

SOLE AGENTS FOR PACIFIC COAST FOR

J. A. Fay & Co.'s Woodworking Machinery,
Bement & Sons' Machinists' Tools,
Blake's Patent Steam Pumps,
N. Y. Belting & Packing Co.'s Rubber Goods,
Sturtevant Blowers and Exhaust Fans,
Tanite Co.'s Emery Wheels and Machinery
Payne's Vertical Engines and Boilers,
Judson's Standard Governors,
Dreyfus' Self Oilers,
Gould Manufacturing Co.'s Hand Pumps,
Platt's Patent Fuse Lighters,
Lovejoy's Planer Knives.

A FULL LINE OF

Belting, Packing, Hose, and Other
Mill and Mining Supplies on Hand.

Send for Illustrated Catalogue.

Continued from page 397.

look better in Peck district. The north tunnel is in a depth of about 250 feet. Its face is in high grade ore, and the pay streak is about two feet wide. Men are kept at work in all the drifts and shafts, and the showing made by the mine is better to-day than ever before. In the south tunnel some excellent ore is being stopped out.

Some work is being done on the Silver Prince, and five tons of very high grade ore were brought in yesterday for shipment to San Francisco.

WORK is being pushed upon the Black Warrior and a very fine character of ore, carrying native silver, is being taken out.

MESSRS. LUKE & Co.'s mill, in Bradshaw basin, is rapidly approaching completion, and will be ready for the reduction of ores about the 1st of July. The mines in the vicinity of the mill are getting out ore ready for reduction by this mill, the advent of which has enlivened everything in Bradshaw district.

THE MESA gold mine, in Big Bug district, is being vigorously worked by D. R. Poland and his associates. The main tunnel is now in 75 feet, and another one has been commenced. There is also an open cut of 75 feet in the mine. Two astras are being used in reducing ore from this mine, and a partial clean-up makes a good showing.

TURKEY CREEK.—*Arizona Miner*, June 12: Mr. John Holmes, of the Goodwin mine on Turkey creek, is in town laying in a stock of supplies. The Goodwin is soon to be favored with a 10-stamp quartz mill, when a large force of men will be put to work on the mine to extract the rich ores contained between the walls, which are seven feet apart. Mr. Holmes has now out on the dump about 15 tons of ore, 10 tons of which it is confidently believed will pay \$400 to the ton.

NEW MACHINERY FOR THE SENATOR MINE.—Two of Paul's pulverizers passed our office to-day en route to the Senator mill. These pulverizers are in the shape of barrels, and each weigh about 5,000 pounds. We have heard Paul's pulverizing dry process highly spoken of, and sincerely hope that they will come up to the excellence claimed for them.

THE Superintendent of the Zalida mine reports to the owners that the ledge is now four feet wide, and that the rich gold streak is widening and the silver-bearing lode holds its richness. Some of these little razor blade veins do pan out now and then in spite of precedents. Get your Zalidas, boys, and don't make up a mouth at your medicine.

Idaho.

GOLDEN CHARIOT.—*Idaho Avalanche*, June 16: Operations are progressing quite satisfactorily at the Golden Chariot. A winze is being sunk on the 13th level about 70 feet south of the shaft, for the purpose of determining the continuance of the ore body encountered in the drift. The work thus far has been attended with the most promising results. A sample of the ore assayed, at a recent visit of operations, went as high as \$300 to the ton, and there is a decided improvement in quality and quantity as the work progresses. A splendid quality of ore is also being taken out of the 7th Minnesota and the 6th Chariot levels, and every development in progress has a most auspicious outlook.

SILVER CORD.—A few days ago Mr. John Ward, who resides in the vicinity of the Silver Cord mine, while sorting the ore on the dump, struck a lump of rock of marvelous richness. With scarcely any exception it is the richest piece of rock ever taken out of any mine in this section of the country. Nor is this all, for the ledge in the mine at a point above the 6th level, from which the rock was extracted, is said to embody an abundant supply of just such rich ore as this. And this was one of the mines that was sold at Sheriff's sale for taxes a few days ago.

EMPIRE.—The developments in the Empire mine still continue to be immense. Indications are more favorable than ever, and it is impossible to predict the extent of the marvelous richness of the bonanza deposits beneath the Empire works. The ledge between the 5th and 6th levels still continues to produce marvelously rich rock, and all the indications connected with the progress of the winze on the 7th level are most favorable for the existence of a magnificent bonanza at a point where the two ledges meet. A considerable quantity of second-class ore has just been crushed, and the bullion yield has been quite satisfactory.

SOUTH MOUNTAIN.—The property of the S. M. G. M. Co., at South Mountain, was sold at auction here on Saturday last for taxes. Wm. Moody bought in the same for Lloyd Tevis, Esq., of San Francisco, the amount paid being somewhere in the vicinity of \$1,475.

SOME 30 tons of Potosi ore crushed here recently yielded \$50 to the ton, or double the amount realized from the previous crushing. The Potosi is a good little mine.

THE flow of water still continues to prove a serious obstruction to the progress of operations at the Belle Peck and some other mines.

ARRANGEMENTS are nearly completed with the creditors for starting up the Oro Fino mine.

Montana.

NEW DISCOVERY.—*Butte Miner*, June 12: The Little Darling silver-bearing quartz lode was located on the 12th day of May last, and crosses Gimlet gulch about three miles from town, just around the point after passing the Burlington lode. The discovery was made on the left bank of Gimlet gulch, where the hill rises very abrupt. Very little work has disclosed a vein some 30 feet in width, the ore carrying, according to assays, from 40 to 140 ounces in silver, besides some lead. A tunnel has been run in on the vein on the east side of the gulch some 20 feet, the ore from which can be seen on the dump at the mouth. The ore is very easily mined and one man working has taken out we should judge about 40 tons in half that number of days, using nothing but pick, shovel and bar. On the west side of the gulch another opening is being made on the vein, and every stroke of the pick discloses quartz of equal value with that in the opposite tunnel.

COPPER MINES.—It is well known that some of our copper mines have been under bond during the past 60 days, by parties contemplating their purchase and the erection of works for reducing their ores. The time for which the property was bonded expired on Saturday last, and those in interest were on hand to consummate the purchase. Only a portion of the property was taken, however, but enough to insure the erection of works at no distant day. This is merely a starter—the first step leading to the placing of nearly all our copper interests into the hands of intelligent and energetic capitalists. What speaks in the highest praise of our copper mining interest, is the fact that the sales just made were to local capitalists, to men identified with the country; men who expect to live and do business in the country; who have been and are still interested in other sections of the Territory, and have had experience and are well posted in all the advantages and disadvantages connected with the business of mining.

Utah.

OPHIR MINES.—*Cor. Salt Lake Tribune*, June 16: Ophir is dull and quiet, extremely so; still, there is a marked improvement within the past few weeks. The mercantile life is slow, yet from the fact that there is but little outfitting for mining and prospecting now-a-days, small quantities of supplies suffice for the mines now working, so that this line of business is pretty much cut down to family trade, of which there is nearly as much as ever. One of the business places here have closed out, some of the buildings have been sold and taken away, as has much of the machinery which was formerly used in the canyon. A well managed custom smelter would do a good business here, from the fact that there is plenty of good base ore of high grade which is now being shipped away in small quantities, time and again being consumed nearly to the extent of the profits of the ores; whereas, a smelter could use them and thus make a grade of bullion that would pay to ship, notwithstanding the exorbitant tariff of the

Union Pacific. A smelter in connection with the Buckhorn mine would make a very valuable piece of property, and we hope ere long enterprise will consummate such a project. This will surely become a good camp again at no distant day. Our mines and reduction facilities will not long be overlooked by capital.

BINGHAM CANYON.—The decline in ore has had a very depressing influence upon our camp, the miners feeling that they might just as well leave the ore in the ground as to extract it and make the smelting fraternity a present of it. If the ore buyers can afford to let their works remain idle for the sake of keeping lead down, we can stand the pressure. It is a poor rule that won't work both ways, and a good pile of ore on the dump looks just as fascinating in our eyes as it would down in Sandy, and probably more so. Bingham to-day never looked better in prospect; her mines are turning out fully as good, if not better, and this part of the canyon is attracting more attention on account of the high grade silver ore it is producing.

Oregon.

CHERRY CREEK.—*Mining-Immigration Journal*, June 15: News from the new gold diggings at Cherry creek represents that there are 50 men at work making good wages. The mines are situated in the heart of an agricultural district, and provisions are consequently very cheap.

The development of the Monumental mine is anxiously watched by a large number, particularly in eastern Oregon. Parties interested feel that should the tunnel now being run prove the ledge in the Monumental to be one of permanence, it will greatly stimulate all other mining enterprises in that section.

Mr. J. S. HOWARD will commence this week the permanent survey of the ditch for the Portland Sterling mining company. It will be 234 miles in length, with a capacity of 4,000 inches. The mining will be conducted in the most experienced manner, principally by the hydraulic method.

I. B. MOORES and Wm. Salmon started up to Quartzville, and will probably be gone a week or more, looking over their interests in that locality. Work on the White Bull mine is progressing favorably, and the company are sanguine of success.

A DAY or two since a Grand Ronde, in prospecting in "Rowan" gulch, struck a rich placer mine, which on the bedrock yielded \$40 to the pan. At Auburn the Graham brothers have also struck rich mines, directly under the town of Auburn, which pay largely.

Another Indian Uprising.

The Nez Perces and Salmon River Indians, in Idaho, have taken the war path and massacred men, women and children at Camas prairie. The warriors number some 2,000, so that the Government has another Indian war on its hands which will take a little time to conclude. Settlers in the Pelouse and Paradise valleys and the country north of Lewiston, Idaho, are fleeing for their lives and going to the towns. The men are sadly in need of arms. Troops have been ordered from a number of forts and are on the way to the scene. Generals McDowell and Howard have been very prompt in arranging for sending the troops, although there are more Indians than soldiers. On Saturday 100 troops with 150 men from Mount Idaho, encountered the Indians at the head of White Bird canyon. The troops dismounted and left a few soldiers and 20 friendly Indians to hold the horses. The Indians opened fire upon the troops and the fighting was continued for some time. The friendly Indians became alarmed, and the soldiers guarding the horses could see that the Indians were getting the best of the fight, and the soldiers were retreating. The Captain of the citizens, Sergeant Lytle, and one soldier were known to be killed. The whole horse guard, Indians and whites, broke and ran, some for Mt. Idaho and some for Lapwai, leaving the horses to run loose over the prairie. Those coming to Lapwai never stopped till they reached the post. Many houses on the prairie have been burned. Another soldier who reached the garrison at 8 o'clock on the morning of the 18th from the fight, reported that the troops were on foot and surrounded by Indians in the canyon, and in a hand-to-hand fight, Col. Perry and about one-half of the command are said to have been killed, and the remainder surrounded and fighting against odds when the soldier left. The Indians engaged in the fight are non-treaty Nez Perces. They, together with other disaffected tribes, number 2,000 effective warriors. There is a general uprising among the savages, and the whole country is wild with alarm. The Indians are massacring men, women and children in Camas prairie and the settlers are fleeing in all directions for safety.

THE *Herald's* London special says: The relations between Russia and England are of the most critical kind short of actual war. The two countries stand on the very verge of hostilities, and the slightest incident might at any time precipitate a conflict. Never since the Crimean war has the position been of such peculiar difficulty, though the relative strength and influence of Russia and England has changed very materially since that period.

THE Committee on Literary Exercises for the Fourth of July celebration, in this city, have chosen Henry George as orator; George H. Jessup, poet; and Henry Edwards, reader of the Declaration. Mr. Barton Hill will probably read the poem. The exercises will take place at the California theater, which has been kindly offered by Mr. McCullough.

THE United States Fish Commissioners, consisting of F. N. Clark, H. E. Quinn and L. Kumlein, arrived in this city on Friday evening. They placed 110,000 fine young shad in the Sacramento river at Tehama.

SENATOR SPENCER, of Alabama, with a large exploring and prospecting party, leave about the 21st for the Big Horn country.

THE San Francisco Benevolent Association distributed \$18,989 in charity last year.

Early History of the Eastern Slope—No. 7.

In concluding this series of articles on the Eastern Slope, we shall be able to barely glance at the official career of some of the more prominent persons connected with the government of Nevada, either through appointment by President Lincoln or by election by the people of the Territory. The following embrace the set of officials first appointed to the several positions named; the most of whom arrived in the Territory with Governor Nye, July, 1861, or came out shortly after:

Benjamin B. Bunker, Attorney General, an amiable, quiet man of correct precedents and good business habits. Without being a brilliant advocate he was a lawyer of fair legal attainments, discharging his official duties in a manner that gave general satisfaction. After being in the Territory for a year or so, not liking the country, he resigned his position and returned to New Hampshire, his former place of residence, Thomas D. Edwards having been appointed his successor. This gentleman, who proved an efficient as well as a popular officer, held the place till the Territorial was superseded by the State government.

Henry Grice, first U. S. Marshal, has, for many years past, been a resident of San Francisco, holding, during most of the time, an office under the General Government. Perry G. Childs was the first Territorial Auditor, and J. H. Kinkead the first Territorial Treasurer. Under their supervision the fiscal affairs of Nevada were conducted ably and discreetly, the foundation for the high credit which the country has always enjoyed having been laid during their administration. A good proof of their financial ability is found in the fact that they succeeded in negotiating from Michael Reese a loan of \$50,000, at a time when the Territorial exchequer was without a dollar, nor had any revenue system yet been established. Shortly after this loan had been effected the value of greenbacks fell to a very low figure, causing the lender much uneasiness lest he should be repaid, as he might have been, in this depreciated currency. When due, the amount, with interest, was paid in gold, whereat Michael rejoiced exceedingly. Both of these gentlemen have, for many years past, resided in San Francisco, where they have been engaged chiefly in mining pursuits.

In the Surveyor General's Office.

There was appointed John W. North, Surveyor General, with Butler Ives, Deputy, and John F. Kidder, Chief Clerk. These were all men of high character, and more than average professional ability, and not often has this branch of the public service been committed to better hands. On the resignation of Gordon N. Mott, Judge of the First District in 1862, North, who was educated to the law, was appointed to that place. His rulings in some of the great mining suits tried before him having excited the hostility of the lawyers engaged therein, he was fiercely denounced by the latter through the newspapers and in public meetings, causing for the time being a great commotion. The judge, however, came out of the conflict unscathed, having been acquitted of the charges made against him at the bar of public opinion. This gentleman, for the past 10 or 12 years, has been a resident of San Bernardino county, California, where he founded the Riverside colony, one of the most prosperous enterprises of the kind yet established in the State.

Ives and Kidder were employed on the several commissions appointed for ascertaining and fixing the boundary line between California and Nevada, and in various other public capacities, in all of which they performed their work in a creditable manner. The former was afterward in the service of the Central Pacific Railroad Company, who held him in high estimation for his faithfulness and capability. He was one day found dead a short distance from his camp, the cause of his death being unknown. As he was at the time a strong, healthy man, free from all bad habits, the event will probably forever remain a mystery. Kidder, after getting through with his labors in Nevada, had charge of several important railroad enterprises on the Pacific coast, in all of which he displayed great constructive and engineering skill. At present he is Superintendent of the Colfax and Nevada narrow-gauge road, of which he was the chief surveyor and supervising builder. Besides making this road a financial success, he has managed it with such caution and vigilance that no serious accident, either to person or property, has happened upon it since its completion, more than a year ago.

The Judiciary.

The members of the Supreme Court consisted of George Turner, Chief Justice, and Horatio N. Jones and Gordon N. Mott, assistant Justices. Judge Turner, after a residence of some years in Nevada, removed to San Francisco, where he has since been, and is still successfully practicing his profession. Judge Mott, having resigned his position on the bench in 1862, was afterwards elected delegate to Congress from Nevada. For some time past he has been living in this city, practicing law, and also acting as a Court Commissioner. Judge Jones, though a well meaning man, and not deficient

in legal learning, was so extremely sensitive to adverse criticism and even the opposing opinions of others, as to render him unfit for the proper discharge of his judicial duties. Aware, himself, of this fact, and being withal disgusted with his rough surroundings, he resigned his office after a short term and returned to Missouri, his former home.

The Council.

An arm of the Territorial legislature corresponding to the senate in most law-making bodies, was composed of nine members; J. L. VanBokelen, from his thorough acquaintance with parliamentary law and legislative usages, having been chosen President, the functions of which position he discharged ably and well. This gentleman was killed in Virginia City some three years ago, through the explosion of dynamite or other dangerous substance with which he was at the time experimenting. Several other lives were involved in this catastrophe; Charles Knox, of San Francisco, a most estimable young man, having been one of the victims.

Dr. J. W. Pugh settled early in Sacramento, and, engaging in trade, also in the practice of his calling, in which he stood well, made considerable money there. He went to Washoe early and succeeded in securing many mining claims. After serving in the legislature to the entire acceptance of his constituency, he followed for a time the vocation of a broker in Virginia City and then returned to Sacramento. A few years after he was afflicted with softening of the brain, which malady increasing upon him, finally necessitated his removal to the insane asylum at Stockton, where he died soon after.

Wm. M. Stewart, with his knowledge of law, proved a very useful member of the legislature, having done much towards molding the code of laws adopted and directing the general action of that body. After representing the State of Nevada for two terms in the United States Senate, he removed to San Francisco, where he is now living, engaged in the practice of the law. Thomas Hannah, one of the most active and influential members of the council, is also now a resident of this city, being largely interested in mining and other business enterprises. Isaac Roop, first Provisional Governor of Nevada, emigrated to the Eastern slope long before the discovery of the Washoe mines. He was the founder of Susanville, in Honey Lake valley, at which place he died about seven years ago. Roop was a man of fine social qualities and a good deal of energy, though marked by that lack of system and thrift common with those fond of pioneer life. Ira M. Luther, also an early settler in the country east of the Sierra, after a diligent and useful term in the Council, visited the Atlantic States, then returned to California, where he is still living. John W. Grier lives with his family at Silver City, Nevada, where he was living at the time he served on the council, he being then, as now, the agent of Wells, Fargo & Co., at that place. There are few better men than "Uncle John," as every one likes to call him, and in fact there is no need for any better. A. W. Pray carries on, as he has done for many years, an extensive lumber business in the Sierra Nevada easterly from Lake Tahoe. He is an energetic business man and has always enjoyed the best kind of a reputation in the community where he has lived. Solomon Geller, a sensible, clear-headed farmer from the Truckee meadows, is still living in that vicinity, a large land owner and the raiser of many sheep.

Henry O. Smeathman, Secretary of the council and who also performed the functions of chaplain to that body, came to his death about ten years ago in a singular manner. While returning with two or three others from a prospecting trip in the Black Rock region, the party was attacked by a band of Piutes. All being pretty well mounted, his companions seeing their danger hurried up their animals and got beyond the reach of the arrows sent after them. Smeathman, however, made no effort to escape, and when the others, looking back, last saw him, appeared to be making Masonic signs, as if he expected thereby to arrest the threatened attack. This availed not, and his escaping companions saw poor Smeathman fall from his horse fatally shot with arrows before they got out of sight. Reaching the mining settlements on the Humboldt, the whites obtained reinforcements and returned to the spot, where they found the body of the unfortunate man quite naked, his clothing, horse and everything else having been seized and carried off by the savages. The victim of this atrocious act had a good horse under him and might easily have made his escape, and by what fatuity he failed to do so will always remain a mystery. Being a powerful young man, capable of making a good resistance, why he offered none when attacked is also something unaccountably strange.

THE Lord Provost of Edinburgh has notified General Grant, through the American legation at London, of the desire of the corporation and citizens to make, in the event of General Grant's visiting Edinburgh, a public recognition of the high estimate they hold of his character and the services which he, as President, rendered to the cause of general peace, particularly in the continued friendly relations between the United States and Great Britain.

A WASHINGTON special says: The well-known philanthropist, W. W. Corcoran, distributed \$20,000 among the poor men and women who were recently thrown out of employment by reason of reductions in the departments.

Items of Interest from the Mines.

We give below items of interest from prominent mines, most of which are collated from letters of the respective Superintendents on file at the offices in this city:

The New England ledge is turning out eight tons of good ore per day. The last crushing of 115 tons yielded \$5,086 in free gold and eight tons of sulphureta.

In the Silver Hill the north drift on the 650-foot level, which corresponds in depth with the 1000-foot level of the Justice, continues in fine quartz.

They struck the foot-wall in the Alpha on Saturday, 23 feet west of main drift, and found no ore.

The ore in the east and west drifts, third level, of the Grand Prize is now worth from \$250 to \$300 per ton.

The connection between the upraise and winze in the El Dorado South has been made.

The mill and furnace of the Advance are running satisfactorily.

On the 1750-foot level, from the C. & C. shaft, the west drift is very large and when complete will have a double track connecting the shaft with the ore vein.

In the Justice a very important change has taken place in the face of north drift, 750-foot level. This is on the east spur of the vein; also a decided improvement has taken place in the face of the south lateral drift on the west spur of the vein on the 750-foot level. Each improvement is producing a better quality of milling ore.

Board of Managers and Standing Committees of the Fair.

The following comprise the Board of Managers of the twelfth industrial exhibition, under the auspices of the Mechanics' Institute of this city:

- A. S. HALLIDIE, Pres't.

HENRY L. DAVIS, Treas.

GEORGE SPAULDING.

HENRY S. SMITH.

JAMES SPIERS.

COLUMBUS WATERHOUSE.

J. B. STETSON.
- P. B. CORNWALL, V. Pres't.

ERNEST L. RANSOME, Cor. Sec.

ASA R. WELLS.

A. L. FISH.

JAMES DUFFY.

JAMES DUFFY.

H. F. HUTCHINSON.

At a meeting of the Board, held on June 19th, the following standing committees were appointed to serve during the continuance of the forthcoming exhibition, which opens August 7th:

- AUDITOR.—C. Waterhouse, J. B. Stetson, James Drury.

BUILDING.—James Drury, A. L. Fish, A. R. Wells.

CIRCULARS AND CLASSIFICATION.—James Duffy, James Spiers, C. Waterhouse.

PRINTING AND ADVERTISING.—Geo. Spaulding, James Duffy, E. L. Ransome.

POWER AND MACHINERY.—James Spiers, A. L. Fish, H. S. Smith.

RULES, REGULATIONS AND AWARDS.—P. B. Cornwall, Geo. Spaulding, H. L. Davis.

TICKETS AND ADMISSIONS.—Asa R. Wells, E. L. Ransome, H. L. Hutchinson.

MUSIC AND DECORATION.—Henry L. Davis, H. L. Hutchinson, P. B. Cornwall.

PRIVILEGES.—A. L. Fish, P. B. Cornwall, H. L. Davis.

LOCATION.—E. L. Ransome, James Spiers, H. S. Smith.

POLICE.—J. B. Stetson, James Drury, C. Waterhouse.

HORTICULTURAL GARDEN.—H. L. Hutchinson, A. R. Wells, Geo. Spaulding.

GAR AND WATER.—H. L. Smith, James Drury, J. B. Stetson.
- Mr. J. H. Gilmore is Superintendent, and Mr. J. H. Culver, Secretary.

General News Items.

PRESIDENT D. C. GILMAN, formerly of the California University, was married at Newport, R. I., last week, to Miss Lillie Woolsey, niece of ex-President Woolsey, of Yale College, and sister of Susan Coolidge, the well-known authoress.

The President and Secretary Sherman have expressed themselves strongly, in private, to the effect that if silver is to be made a legal tender, custom dues and interest and principal of the public debt must be expressly exempted from the operations of the Act.

A NEWBURG (N. Y.) dispatch says: The 17-year locusts are here in abundance. They keep up a disagreeable hum-drum noise, but farmers do not think they will be dangerous in destroying the crops. Chickens and turkeys feast on them, and consequently it will be a good year for poultry.

Geo. K. Fitch brings suit against Charles De Young and Michael De Young to recover \$5,000 damages, for an alleged libel published in the San Francisco Chronicle, of November 30th, 1876, in which it was editorially charged that plaintiff and Loring Pickering had sold the use of their columns to the railroad company.

No correspondents are now allowed to leave the Russian headquarters. Those who are fortunate enough to be at the scene of fighting cannot use the telegraph to send their news forward. Grand Duke Nicholas has shut off every avenue by which intelligence of the forthcoming great move of his army can get abroad. The railroads, post-roads, telegraph lines, and even the mail bags are under his censorship.

The California quicksilver mining company are taking from their mines, according to the Yolo Mail, from 70 to 100 fasks of quicksilver per week; not that many per month, as we recently stated on the same authority.

A PARTY of 20 miners, bound for Big Horn, were fired upon by Indians when about 60 miles out from Deadwood. One of the miners was slightly wounded.

PATENTS AND INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

WEEK ENDING JUNE 5TH, 1877.	
101,529.	HOISTING MACHINE, (Hydraulic).—F. G. Hesse, Oakland, Cal.
101,548.	BAKING PAN.—J. H. Pitts, S. F.
101,561.	EXPANDING REAMER.—R. Blair, S. F.
101,035.	BEE HIVE.—T. A. Atkinson, Merced, Cal.
101,037.	QUICKSILVER CONDENSER.—R. F. Knox, S. F.
101,733.	CONVERTIBLE CHAIR.—J. P. True, Ponce de Leon, Col.
REISSUES.	
7,790.	KEY HOLE GUARDS FOR LOCKS.—C. H. Covell, Stockton, Cal.
FOR WEEK ENDING JUNE 12TH, 1877.	
101,767.	TOOL HANDLE.—C. Groth, S. F.
101,805.	MERCURY CONDENSER.—W. H. Long and A. W. Castle, San Jose, Cal.

And in accordance with law and an order of the Board of Trustees, made on the thirtieth day of April, 1877, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at the salesroom of J. Middleton & Son, No. 310 Montgomery Street, San Francisco, Cal., on the twenty-fifth day of June, 1877, at the hour of two o'clock, P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

Office, No. 320 California Street, Room No. 5, San Francisco, Cal.

Consolidated Bonanza Gold and Silver Mining Co.—Location

of principal place of business, San Francisco, California. Location of works in Eagle and Washoe Valley Mining District, Ormsby county, Nevada.

NOTICE is hereby given that at a meeting of the Board of Trustees, held on the fourth day of June, 1877, an assessment, No. 1, of 10 cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary, at the office of the company, No. 19 First Street, San Francisco, California.
Any stock upon which this assessment shall remain unpaid on Tuesday, the tenth day of July, 1877, will be delinquent and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the thirty-first day of July, 1877, to pay the delinquent assessment together with costs of advertising and expenses of sale. By order of the Board of Trustees. WM. MARTIN, Secretary.
Office No. 19 First Street, San Francisco, Cal.

Iron and Machine Works.

PACIFIC ROLLING MILL COMPANY,

SAN FRANCISCO, CAL.

Established for the Manufacture of
RAILROAD AND OTHER IRON

Every Variety of Shafting,

Embracing ALL SIZES of

Steamboat Shafts, Cranks, Piston and Connecting Rods, Car and Locomotive Axles and Frames,

Hammered Iron of Every Description and Size.

Orders addressed to PACIFIC ROLLING MILL COMPANY, P. O. Box 2032, San Francisco, Cal., will receive prompt attention. OFFICE: 16 First Street.
The highest price paid for Scrap Iron.

THE RISDON

Iron and Locomotive Works,

INCORPORATED.....APRIL 30, 1868
CAPITAL.....\$1,000,000.

LOCATION OF WORKS:

Corner of Beale and Howard Streets,

SAN FRANCISCO.

Manufacturers of Steam Engines, Quartz and Flour Mill Machinery, Steam Boilers (Marine, Locomotive and Stationary), Marine Engines (High and Low Pressure). All kinds of light and heavy Castings at lowest prices. Cams and Tappets, with chilled faces, guaranteed 40 per cent. more durable than ordinary iron.

Directors:

Joseph Moore, Jesse Holladay, C. E. McLane,
Wm. Norris, Wm. H. Taylor, J. B. Haggin,
James D. Walker.

J. W. QUICK, MANUFACTURER,

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

Machinery.

The Ingersoll Rock Drill

Is Extensively Used in the East and

TAKES THE PLACE OF ALL OTHERS,

Wherever introduced, because it can be run with less power, labor and repairs, and do more work than any other Drill in the market. It has but few parts, is easily handled, being light, and has AUTOMATIC FEED, which saves labor. WE ASK FOR TRIAL AGAINST ANY COMPETITOR. For particular information regarding Drills or Air Compressors, send for circular to

J. B. REYNOLDS,

320 Sansome Street

(Room 10.)

THE O'HARRA CHLORIDIZING FURNACE

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing 20 Tons in 24 Hours by this Process:

One man.....	\$ 4 00
One man.....	3 00
Wood—2½ Cords at \$3 per cord.....	6 25
Salt—1,600 lbs at 2½ cents.....	40 00

Cost of 20 tons.....\$52 25
Cost of one ton.....2 61½

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in Peavine District, Nev., and at the Exchequer mill, Alpine Co., Cal. For further information, apply to

D. J. O'HARRA,

Reno, Nevada.

THE ONLY PERFECT

BALANCE SLIDE VALVE

That is made. Applied without extra charge to Engines manufactured by us.

SLIDE

VALVE.

PRESCOTT, SCOTT & CO.,

Large advertisements at favorable rates. Special or reading notices, legal advertisements, notices appearing in extraordinary type or in particular parts of the paper inserted at special rates.

THE VICTOR ROCK DRILL.

This machine is so simple in its construction that any person can understand and run it. The DOUBLE GOUGE BIT, patented with this Drill only, is one of its specialties, as it feeds and cleans itself. The machine is a hand Drill and can be operated by two men, who will do the work of ten in the ordinary way. In a word, it is a labor-saving machine which has no parallel, and as such we offer it to the public. For State or Territorial rights, or machines, apply to

MacDOWELL, KINZER & CO.,

216 Sansome street, San Francisco, Cal.

Patent Riveted

Clothing,

14 & 16 Battery St.
San Francisco.

These goods are specially adapted for the use of FARMERS, MECHANICS, MINERS, and WORKING MEN in general. They are manufactured of the Best Material, and in a Superior Manner. A trial will convince everybody of this fact.

Patented May 12, 1873.
USE NO OTHER, AND INQUIRE FOR THESE GOODS ONLY.

Gold and Silver Sulphurets Purchased

At the highest prices; also, treated on Commission at low rates.

DEETKEN & KRUSE'S Reduction Works.

GRASS VALLEY, NEVADA CO., CAL.

San Francisco Cordage Company.

Established 1856.

We have just added a large amount of new machinery of the latest and most improved kind, and are again prepared to fill orders for Rope of any special lengths and sizes. Constantly on hand a large stock of Manila Rope, all sizes: Tarred Manila Rope; Hay Rope; Whale Line, etc., etc.

TUBBS & CO.,

611 and 613 Front Street, San Francisco.

\$55 a Week to Agents. \$10 Outfit Free. P. O. VICKERY, Augusta, Maine.

SNOOK'S PATENT TANK FILTER.

It is self-regulating, will last many years without renewing filtering material. Is simple, durable, easily cleaned, and not liable to get out of order. A sure preventive against snakes, worms, bugs and all other impurities in the water. It will filter all the water required for any dwelling house, and is not expensive. These filters are expressly designed to use in place of a tank. May be connected to any tank and through the usual pipes supply all the house, or the water may be used direct from the filter, where no tank is required for other purposes. Every house should be provided with one and thus avoid one of the most fruitful sources of disease. Full satisfaction guaranteed and filters kept repair free of expense. For sale by

\$1,000 Challenge Ore Feeder,

AWARDED FIRST PREMIUM

At the Tenth Industrial Fair of the Mechanics' Institute.

It may be considered as now fully demonstrated, by careful and long-continued experimentation, that the plan upon which a perfect ore feeder must be constructed is that of the carrier, and not that of the shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply dropped. Spasmodic or jerky contrivances will not answer the purpose.

REFERENCES.

A letter received from the Julian Mill, Newcastle, says of the Carrier Feeder: "It is the most perfect Feeder we have ever seen; don't see how any mill can do without them."—A letter from Mr. C. C. Belding, of Amador County, speaks in the highest terms of them. Two of the machines were shipped to the Bunker Hill Mill, also Gover Mill, Amador County. Mr. Stevenson, of Boston Mill, Gold Hill, Nevada, says they are the best Feeder he has ever seen. Salsby Mill, Tuolumne County—California Company, Nevada City. Omaha Gold Mining Company, Grass Valley.—St. Patrick Mill, Placer County.

\$1,000 CHALLENGE.

Backward in Coming Forward.

C. P. Stanford Fails to Come to Time on the Challenge of \$1,000 to Test the Merits of His Ore Feeder as Against Mine. The Challenge is Still Open to Him or any one else. GENTLEMEN, Put up or Shut up.

A letter has been received from the Crescent mine, Plumas County, in which it states that the Tulloch is a failure as against the \$1,000 Challenge Feeder of Hendy's.

We warrant the machines to give perfect satisfaction, and to be a better and more durable Feeder than any other in the market, and will sell them as cheap as any other of its class.

For Description, Send for Circular to

PATENTED

CAST STEEL SHOES AND DIES.

Guaranteed Cheaper than the Best Iron.

IMPORTANT NOTICE.

Reduction in Price from 16 Cents to 12 Cents Per Pound.

Owing to our largely increased business, the present low price of Iron from which our Steel is manufactured, and the improved facilities for casting and forging, we take great pleasure in announcing that from and after this date we will supply our IMPROVED CAST AND FORGED STEEL SHOES AND DIES FOR QUARTZ MILLS at twelve cents per pound, delivered at San Francisco or Sacramento, instead of sixteen cents, as heretofore.

We also furnish Steel Plates for Blake and other Ore Crushers, Steel Gut Gearing, etc., for Mills and Hoisting Works, Steel Pan Shoes, Battery Cams and Tappets, etc., etc.

Address all orders, with dimensions or drawings, to

Testing and Working Silver Ores.

The above is the title of an illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron, which has just been issued by Dewey & Co. Mr. Aaron has managed to give many useful hints and suggestions, free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope.

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation, test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working sample, appliances for testing, roasting, etc. Under the head of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Patchen's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the head of "Leaching Processes" are the titles, Smelting, Mexican process, Chilean process, Kroehnke's process, etc. Under "Pulverizing Machines" are described the arastra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improvised retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tailings and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

The book is a serviceable one for miners' and prospectors' use. Price, post free, \$2.00. Address Dewey & Co., MINING AND SCIENTIFIC PRESS, 224 Sansome Street, San Francisco.

Questions of the Times.

Which are the most reliable watches?

American watches, they are driving those of foreign make out of the market.

Which is the best American watch?

The New York watch, made at Springfield, Mass.

Why is it the best watch?

Because it is substantial in all its parts, constructed on the best principles and embodies those improvements which experience has shown to be the most desirable.

Why is the New York Watch so popular?

Because in buying one you are sure of getting a good time-keeper. While purchasing a watch of most other makes is like investing in a lottery—a great many blanks to one prize.

Which is the cheapest watch?

The most economical is the New York watch. For you can get one of these excellent time-keepers for less than it costs in a short time to patch up a poor watch, which benefits no one but the repairer.

Where can I get a New York Watch?

By addressing the long established, practical Watch-makers and Jewelers, DEWEY & JORDAN, 493 Montgomery St., San Francisco, who will send you a descriptive price list, including the following styles of movements: "John Hancock," Geo. Sam. Rice," "Chas. E. Hayward," "Aaron Bag," "Theo. E. Studley," "Chester Woolworth," "Frederick Billings," "Railway," "John L. King," "E. W. Bond."

HAMILTON, N.Y., May 28th, 1876.

To Messrs. Dewey & Co., Patent Agents:
GENTLEMEN:—I write to acknowledge the receipt by express of the U. S. letters patent, on my invention for breech loading ordnance, and to tender you again my very sincere thanks for the careful attention you have bestowed upon my application since I first placed it in your hands, for the evident great interest you have manifested in it, and for the uniform patient and cheerful courtesy which has constantly marked your correspondence in reference to it. I have had some dealings with other agencies in the same line in times past, and I can assure you that my correspondence with yours has been more pleasant and satisfactory than with any others, and I shall always take great pleasure in recommending your agency to any and all my acquaintances without hesitation or reservation, as I should certainly prefer to entrust my own business in your hands should I have any to transact in the same line hereafter. Yours, etc.

J. R. N. OWEN.

UNITED STATES Mineral Land Laws, Revised Statutes, AND INSTRUCTIONS AND FORMS UNDER THE SAME.

We have just issued a pamphlet containing the General Mineral Land Laws of the United States, with instructions of the Commissioner of the Land Office. The contents of this pamphlet comprise all of the Government laws with relation to mineral lands of interest to the mining community, as follows: Mining Statute of May 10th, 1872, with instructions by the Commissioner of the Land Office; Mining Statute of July 26th, 1866; Mining Statute of July 9th, 1870. Forms required under Mining Act of May 10th, 1872, as follows: Notice of Location; Request for Survey; Application for Patent; Proof of Posting Notice and Diagram of the Claim; Proof that Plat and Notice remained Posted on Claim during Time of Publication; Registers' Certificate of Posting Notice for Sixty Days; Agreement of Publisher; Proof of Publication; Affidavit of \$500 Improvements; Statement and Charge of Fees; Proof of Ownership and Possession in Case of Loss or absence of Mining Records; Affidavit of Citizenship; Certificate that no Suit is Pending; Power of Attorney; Protest and Adverse Claim; Non-Mineral Affidavit; Proof that no Known Veins Exist in a Placer Claim, etc. There is also given the U. S. Coal Land Law and Regulations thereunder. The work comprises thirty pages, and will be sold, post-free, for 50 cents. It should be in the hands of every one having any mining interests. DEWEY & CO., Publishers of the MINING AND SCIENTIFIC PRESS, S. F.

OUR AGENTS.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

"Faith and Confidence."

LIVERMORE, Oct. 1st, 1875.

MESSRS. DEWEY & Co., Patent Solicitors: Gentlemen:—Yours of the 29th ult., containing my patent to Elevated R. R. duly received, and I hereby return my sincere thanks to the MINING AND SCIENTIFIC PRESS Patent Agency for your promptness and honesty in regard to our business connections. I have received a flood of circulars from Eastern firms, desiring to deal with me, but I have declined any communication with them and prefer to see circumstances will permit, to negotiate with and patronize a home institution; one in which I have faith and confidence—DEWEY & Co.

Again thanking you for your promptness in securing my patent, I remain, obediently yours,
WM. H. HARRISON.

A VALUABLE MINING BOOK.

BY J. S. PHILLIPS.

The Explorers', Miners and Metallurgists' Companion 682 pages, 83 illustrations. Second Edition. A California publication.

OPINIONS OF THE PRESS.

The book is exactly calculated to suit the views and meet the requirements of those for whom it has been written.—*London Mining Journal*.

The most practical and comprehensive work on mining subjects extant, and valuable book of reference.—*Mining and Scientific Press, San Francisco*.

We know of no work on these subjects in the English language at once so comprehensive, practical and intelligible.—*S. F. Golden Era*.

He has rendered to the leading industry of the coast a valuable service—has furnished the millman and miner a safe and much needed practical guide.—*Overland Monthly*.

This book, which treats in an intelligent and practical way on almost every topic connected with mining pursuits, should be in the hands of every millman, metallurgist, prospector and miner on the Pacific coast. Even the capitalist, and, in fact, every person already engaged in, or likely to become interested in the business of mining, will find in this comprehensive work an amount of information that they cannot afford to dispense with.—*S. F. Commercial Herald*.

This book is free from trash, and solid throughout; all its matter is intelligible to men of ordinary education, and all of it is valuable to miners.—*S. F. Daily Alta*.

In the several sections the work is eminently practical. Is very comprehensive, and contains a great deal of useful information which cannot be obtained from the previous books that have been written on these subjects.—*S. F. Daily Examiner*.

It affords a vast quantity of information as to the appearance and value of different ores.—*S. F. News Letter*.

It is the best single English treatise we know for the use of prospectors and practical miners.—*The Engineering and Mining Journal, New York*.

Sold by Dewey & Co., at this office. Price \$10.50.

Constitutional Tendencies.—The way in which different individuals are affected by the same causes of disease depends upon the constitution and temperament. Some persons, for instance, are prone to fevers, some to bilious attacks, and others to nervous affections. In all cases where a peculiar susceptibility to any variety of disease exists, the tuning, regulating and purifying operation of

Tarrant's Effervescent Seltzer Aperient Will be found the surest safeguard against an attack. Individuals of a bilious and constipated habit, or subject to dyspepsia, whose nerves are easily excited, should frequently resort to this refreshing saline corrective, especially in warm weather. It is no less potent as a preventive than as a remedy.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of mention:

IMPROVED DEMIJOHNS CASE.—Carlton Newman, S. F. The necessity of protecting such large bottles or demijohns as are intended to contain corrosive, dangerous or valuable liquids, has resulted in establishing encased bottles as an article of commerce. These encased bottles consist of an outside wooded case or boxing, inside of which the bottle or demijohn is placed and surrounded with suitable elastic packing, which protects it from being broken by ordinary jolts and jars, etc. A necessary feature of this business is that the box or case shall be so constructed that the contents of the bottle or demijohn can be poured out without taking the bottle or demijohn out of the case, and without spilling any of its contents. This has been accomplished heretofore by narrowing the top of the box on two sides, from a point opposite the swell of the bottle upwards towards its top and leaving a side opening through which the liquid could be poured when the box or case was tipped upon its edge; or by making the top of the box flat and allowing the neck of the bottle to project above it through a hole in the top. In the first named class also the fastening screw which secured the cover to the box was left to project above the cover. These cases are, however, objectionable, because they cannot be placed one on top of the other, so that in packing them in cars or other vehicles the cost of transportation is heavy. The object of Mr. Newman's last invention in this direction therefore, is to construct the cases or boxes of a uniform size from bottom to top, and leave this top perfectly flat and unobstructed, and at the same time provide means by which the contents of the bottle or demijohn can be poured out without removing the bottle or demijohn. The invention also includes other improvements. Mr. Newman as proprietor of the glass works in this city has use for a large quantity of these cases.

CONDENSERS.—Wm. H. Long and A. W. Castle, Santa Clara. In the condensation of mercurial vapors it has long been customary to perform this work in dry chambers, which are kept cool in various ways, and in some instances a spray of water has been showered down through a tower to meet the upwardly rising vapor so as to condense it. It has not hitherto been found possible to introduce mercurial vapors beneath water so as to condense them by actual contact, on account of the difficulty in properly discharging such vapors at the bottom of a tank, and because of the pressure necessary to overcome the weight of the water and the consequent back pressure and attendant leakage of fumes between the furnace and condenser. These difficulties these inventors design to overcome by the use of this invention. The condenser consists of a vessel where the vapors are conveyed beneath the surface of the water contained therein, by the centrifugal force caused by the motion of hollow open-ended arms which unite with the central hollow conveying tube, and are caused to rotate with it by suitable mechanism. A supply of cold water is kept up, a suitable trap is provided for, withdrawing the metallic mercury without the water, and stops are placed within the condenser to prevent the rotation of the water by the action of the arms. Each chamber is provided with its own exhausting or vacuum-producing mechanism, so that as many as desired can be used without producing any back pressure or influence upon any of the others.

Of 810 acres in the city boundaries of St. Johns, N. B., 400 acres are burned over, and 20,000 residents are rendered homeless. They have left the city or are under tents. The loss is still estimated at \$20,000,000, and the insurance, so far as known, is about \$8,000,000. It is said all the offices will pay. The Imperial, Etna, etc., lose \$2,000,000; North British, \$1,000,000; Queen, \$800,000; Northern, \$500,000; Royal, Stadacona and others, heavy but not ascertained; Commercial Marine, \$300,000.

Pacific Coast Coal Mines.

We have received from Bancroft & Co. "The Coal Mines of the Western Coast of the United States," by W. A. Goodyear, M. E. This work is a most valuable addition to our industrial literature, filling, as it does, a hitherto neglected but important field. The reputation of the author is sufficient guarantee that the book is no trashy compilation, but has been written with care and an intelligent and scientific knowledge of the subject. Mr. Goodyear was for a long time connected with the State

first treats of the California mines, the Mount Diablo coal field and details concerning it, the Corral Hollow field, the Livermore mine and other coal localities. The second chapter treats of the Oregon coal fields, the third describes the coal mines of Washington Territory, and the fourth gives the cost of production at the Mount Diablo mines, statistics of production and trade, and relative values of different coals. In speaking of the Coos Bay coal mines, Mr. Goodyear gives some striking examples of the recklessness with which the money of stockholders is squandered by ignorant men, and costly works put up before they were sure of

THE "SHERIDAN" CAMP LOUNGE.

Geological Survey, and his professional duties have given him exceptional advantages for obtaining information concerning the coal mines of the coast. The volume before us is mainly the result of his own work, travels and observations, extending over a period of nine or ten years, during which period he has done more work in, and been personally

any mines. He states that in the immediate vicinity of Coos Bay not less than a half million of dollars have been lost in this way, nine-tenths of which might have been saved if the advice of a competent engineer had been sought and followed. Mr. Goodyear concludes that the days of the old Mount Diablo mine are numbered. Since the miners strike in October, 1876, the Pittsburg Co. ceased operations on the Clark bed entirely, and withdrew the pump from the lowest level of that bed. Since that time their mining has been confined to the "little vein" in the old Eureka ground, and to the Black Diamond bed. The Union mine was entirely closed on the 1st of December, 1876, and the mine entirely abandoned. Of the old companies, there only remain at work the Pittsburg and Black Diamond companies. In the face of heavy and increasing cost of mining, these mines must succumb to the better quality, and eventually, the lower cost of production and transportation of the coals of Washington Territory and British Columbia. Outside of the hitherto unworked eastern portion of the Mount Diablo coal field, Mr. Goodyear thinks there is no other coal field yet known in California which gives promise of being able to compete, to any reasonable extent, with the northern mines. In conclusion, the author says:

Neither is it probable that the mines of Coos bay, the only ones yet worked in Oregon, will be able many years longer to continue work at a profit in the face of the Washington Territory coals. For, though the distance from San Francisco to Coos bay is only about one-half as great as it is to Puget sound, yet the shallow and often unsafe character of the bar at Coos bay, the small size of the vessels that can go there at all, and the uncertainties which often attend the movements of even these small vessels, are such that the rates of freight from Coos bay have generally ranged as high and have often been actually higher than they were from Seattle; while it is more than probable that a company that owned and ran its own suitable steam colliers, could transport coal from Seattle to San Francisco at a considerably lower cost per ton than they could do from Coos bay. Moreover, the cost of mining at Coos bay is greater than it is at Seattle, while at the same time the quality of the Coos bay coal, for domestic purposes as well as for steam, is decidedly inferior to the more northern coals. It is unquestionably to the mines of Washington Territory and of British Columbia that this Pacific coast must look hereafter both for its chief domestic and its nearest and most reliable foreign supplies of that indispensable necessity of all civilized communities—a good article of coal.

A FEARFUL tornado occurred in Iowa, Missouri and Illinois on Sunday night, destroying a great deal of property.

Improved Dumping Device.

The illustration on this page shows an improved dumping device, invented by Wm. Willes, of Salt Lake City, which is excellently suited for loading and unloading carts and other vehicles, vessels, etc., when the same are used for transporting any substance which may be dumped without injury, such as ore, earth, stone, coal, and grain. The invention will also be found useful in building operations, for handling mortar and concrete. It consists of a receptacle, triangular in section, and shaped either as shown in the engraving, or in forms slightly modified therefrom. This is suspended by a looped bail from the sides, as shown. One side, A, Fig. 1, is secured to a rod which enters apertures in the adjacent ends, so that said side, A, is pivoted or hinged so as to swing open, and thus allow the contents of the vessel to escape. To the middle of side A, is pivoted a bar, B, the motion of which is limited by long keepers, and the extremities of which, when the side is closed, fall into hooks on the ends of the bucket. One of these hooks turns upward, the other downward, so the bar B, by being simply turned on its pivot, becomes engaged with them. It may then be fastened (so as not to be dislodged by any chance shock), by a pin passing through the bill of one hook, as shown at C. Of course, while the earth, etc., is in the bucket, the side, A, is kept closed; but when it is desired to dump the contents, the pin, C, is removed, the bar moved out of the hooks, and the side, A, is forced open by the weight of the material above it, which is thus discharged.

In the bucket shown in Fig. 2, a partition D, is used inside the swinging side, A, so that the orifice made by the opening of the latter is thus rendered smaller. This arrangement is best suited for buckets used for sacking grain, where the discharge is made into a comparatively small aperture. For further particulars address Messrs. Willes & Rowe, Salt Lake City, U. T.

Comfort in Camp.

During the hot weather that has prevailed of late we doubt not that many a dweller in the city has wished that he could take to the woods and for a time imitate the life of the "noble savage."

There are some things, however, about camp life that are not altogether agreeable, as, for example, rheumatic twinges from sleeping on the ground, and in some places the mosquitoes are an intolerable nuisance at night.

We give herewith an illustration of the "Sheridan" camp lounge, which is coming into very general use among military men, sportsmen, prospectors and others who wish to carry a light bed that can be set up anywhere.

The frames are of wood and iron, covered with strong canvas. The support for the mosquito bar is made of copper wire, so that it also can be folded for packing.

The "Sheridan" camp lounge has jointed side rails, mosquito bar canopy and pillow attachment. Size of case, two inches by seven inches by 23 inches. A beautiful, compact, comfortable and convenient lounge.

Mr. C. H. Mosely, of 415 Sansome street, is the agent for these goods upon this coast.

The main points of excellence which he claims for them are strength, comfort and portability.

The testimonials from purchasers include many names of prominent persons who use them in almost every situation; in houses, on the lawn and in the wilderness. The article is so compact and light when folded that it can be sent by mail or express to any address.

PATENT SUIT.—An action has been brought in the United States Circuit Court by W. T. Garratt, the owner of the Hooker pump patent, against W. C. Wilcox and B. F. Baker, manufacturers of the Wilcox steam pump, to enjoin the defendants against infringing upon a certain patent granted to William D. Hooker on the 6th of December, 1870, for "an improvement on direct-acting steam engines, constructed with auxiliary valves," and for an accounting, etc.

WILLES "LIGHTNING DUMPER."

more familiar with the actual condition and workings of the various coal mines of the Pacific coast than any other engineer has done. Mr. Goodyear says in the preface that the object he has had in view has not been so much to discuss the geological character of the Pacific coast coal fields as to give, what has never yet been published, a full and intelligible description of the mines themselves, as they exist to-day.

The book is divided into four chapters. The

The Palisade Coal Vein.

We have duly chronicled, says the *Eureka Sentinel*, the developments made in the coal mine recently discovered at Palisade, and are pleased to learn that the prospect for opening and developing a large and permanent vein is daily increasing. Messrs. Ferguson and Young, the discoverers of the mine, are both old coal miners; Mr. Ferguson having worked for a number of years in the Pennsylvania coal fields, and Mr. Young has served his apprenticeship in the coal mines of England. Soon after the finding of the Palisade vein, a company, consisting of the most prominent citizens of that burg, was organized and sufficient capital to sink a shaft and prospect the find was subscribed. The vein is situated about four miles north of the town, and a shaft has been sunk on it to a depth of 30 feet, and from the surface down the coal has increased in quantity and quality. A large quantity has been brought into Palisade and submitted to various tests, such as burning in a forge, under a locomotive boiler and in heating stoves. All these experiments have resulted satisfactorily, the coal burning freely, giving a welding heat in the forge and leaving but little ash. There is but very little sulphur in it, and the specimens we have seen have the gloss and luster of bituminous coal, clearly distinguishing it from lignite. The prospecting shaft is very small, but besides the large quantity sent into town, the company have a number of tons on the dump, and on Wednesday extracted one lump that will weigh over a ton. As an evidence of the faith that the company have in the mine, we learn that they refused a cash offer yesterday of \$5,000. The stock is divided into 11,000 shares, and a small number of 100-share lots have been disposed of at \$1 per share. These were sold to friends of the original owners, but there are none in the market even at that price. We have in former articles dwelt upon the advantages that would accrue to the Central Pacific railroad if coal in any quantity should be developed by future explorations, and we understand that the offer yesterday was made by the authorized agent of that company. They are very desirous of escaping from the clutches of the Union Pacific, who now exact a tribute for every ton of the vast quantity used on the Central Pacific road. The railroad runs through a treeless desert for a length of 500 miles, and the existence of a coal bed at a central point in this waste would save a large amount in transportation, while if the deposit should come under their control, the first cost would be reduced to that of extraction. There is another view of the matter that effects Eureka. As the mountains in this vicinity are denuded of their timber growth, the charcoal supply in the near future becomes a serious question. There is no present scarcity, but the price of the article is the heaviest item of expense encountered in the reduction of our ores. The contiguity of a large coal deposit of a quality that will coke readily, would solve the question, and render valuable the millions of tons of low grade ore that at present cannot be worked at a profit. Our furnace men have been impatiently awaiting developments out at Pancake, and their attention will now be drawn to the Palisade coal fields. Of course these are mere speculations, but the owners of the vein are very sanguine, and feel sure that they have got a good thing, notwithstanding that Prof. Frank Stewart denies the possibility of the existence of any black diamonds in the sage brush. Scientific theories are apt to be upset (the silver deposits in Leeds district, for instance), and if he puts on his spectacles he will find several tons of the article at the Palisade coal mine. If ten tons of coal can be found in that mine, there is no cogent reason for denying the occurrence of ten million tons in the same neighborhood. Facts are hard things for would-be scientific theorists.

Like a Romance.

Stephen Lanehart died two weeks since at Rush creek, Trinity Co. He was an old resident of the county, having gone there in 1851. His death, says the *Trinity Journal*, recalls an incident in his life which would be a good foundation for a romance, as indeed it has been. Lanehart was pretty well posted as to Indian character, and on one occasion turned this knowledge to good account. The old Indians, who were grown before the county was settled, retained many of their old habits and customs, one of which was upon the death of a person to bury or destroy everything of which he died possessed. Prior to March, 1852, there was constant war between the whites and Indians, and none can ever know how many of the adventurous spirits who crossed the mountains in search of the golden treasure of the Trinity and its branches, fell beneath the noiseless arrows of the treacherous natives. It was not until years after peace had been established that the Indians outgrew their fear of vengeance, and told of some of their exploits in which little parties of miners and solitary travelers had fallen victims to their vengeance, and many a spot along Trinity river was marked by them as the scene of such an occurrence. Among others told of was a man traveling on a white horse. Somewhere near Point Bar he was attacked and killed, his horse eaten, his rifle thrown into the river, and his body buried or concealed. But he made a brave fight, and wounded one of his assailants in the arm. The Indians had no knowledge of surgery, and the wounded arm mortified and fell off. The dead man had a large sum in gold dust with him,

which was taken possession of by his captors. When the wounded man's arm and hand came off it was buried in a little flat half a mile or more below the mouth of Rush creek, and the gold dust taken from the white man's body sown broadcast above the buried hand. Lanehart heard the Indians talking of this many years after, and set himself to work to find out the place where the hand was buried and the treasure strewn. This was not an easy task by any means, for Indian superstition prohibits them from talking of the dead in any manner, believing that to mention a deceased Indian by name would bring his spirit around. He and others finally succeeded in getting them to divulge the fact that the hand was buried in a field belonging to Sherrin Chamberlain. They went to work and were ultimately rewarded by finding the strewn treasure. We never learned the exact amount recovered, but it was over \$1,000.

The belief is prevalent among those old residents who know the Indian characteristics, that many other places in the county have been enriched with treasure stolen from the whites during the first three years after the mines here were discovered. Certain it is that there have been some marvelous "strikes" which can be accounted for in no other way, of places that yielded unexpected large sums for a day or two and then came down again to the old standard. But the case we have mentioned and that of Jenkins, who took some \$900 from an Indian grave on one of the forks of Grass Valley creek, are the only instances in which it was known to a certainty that the treasure had been buried by the Indian thieves who took it from the original owners.

Working Flue Dust.

Last February, says the *Eureka Sentinel*, Mr. L. Colbath, a Salt Lake mining operator, and owner of large smelting works some six miles from Salt Lake City, came to Eureka and bargained with the Eureka Consolidated company for the purchase of the immense accumulation of flue dust at the Consolidated reduction works. A sale was effected at the rate of eight dollars per ton, and it was calculated that the amount to be delivered would reach 10,000 tons. It was known that the flue dust was very valuable, samples of it assaying from \$40 to \$50 per ton in gold and silver, and carrying a large percentage of lead and iron. A great many experiments have been made at the different furnaces to find some method of working the article so as to leave a margin of profit, but with very little success, and the dust carried off by volatilization and caught in the condensing flue has at most of the furnaces been allowed to accumulate on the dump pile. The Richmond company was an exception to this rule, that company having reworked it in the form of slime, but experienced smelters have been of the opinion that nothing was gained by this method, the added moisture and increased fuel more than counterbalancing any profit derived from the second working. Be this as it may, the sale to Messrs. Colbath & Co. was consummated, and Mr. Clark, one of the Salt Lake firm, having negotiated special rates with the railroad companies—\$13 per ton freight from Eureka to Salt Lake—commenced shipping the article. The Utah ores lack iron necessary for smelting and fluxing, and it was calculated that as the dust carried 20 per cent. of that metal, it would in a great measure dispense with the necessity of buying iron ore and leave the precious metals as a profit on the speculation. In this way was the fact accounted for that Salt Lake smelters could ship the dust from Eureka and work it at a profit. Mr. Clark shipped 500 tons, when the forwarding was interrupted for a period. This was in consequence of certain discoveries having been made in regard to methods of working it, a discovery that dispensed with smelting entirely, and introduced an old and very simple process. Mr. Colbath, in conjunction with one of the best experts in the Territory, Mr. Wallace, tried a number of experiments as to the best method of reduction. Finally the idea occurred to them that the pan process, the same as used in an ordinary quartz mill, might solve the problem. Five tons of the dust were shipped 40 miles to a distant mill, and we understand that it was treated the same as the pulp from underneath the stamps. We will not be positive on this point, as the discoverers are very reticent, but the dust was run through the pans and the result was that the working process gave a return of within \$1.43 of the fire assay. As soon as this experiment proved successful, Mr. Clark proceeded to San Francisco and opened negotiations with George C. Clark, wholesale paper dealer in that city, and principal stockholder in the Lemon mill of Eureka, for the lease of the mill property. The negotiations have been pending for a month past, during which time we have been in possession of the facts, but under a pledge of secrecy. A. D. Haskell, a stockholder in the mill, and authorized agent of the Lemon company, has leased it to Messrs. Clark & Wallace, who will at once renovate and put the mill in order. We understand that they will not only work the dust by their process, but also any free ores that may be found in the vicinity.

The importance of the enterprise to Eureka can hardly be exaggerated. The loss by volatilization is estimated at 13 per cent. on every ton of ore that goes into the furnace, and if this process of working that wastage is a success, it adds that much to the value of all the ore extracted, less the difference between the returns and the fire assay, a very small one, as shown.

Private Railways.

A new line of railway to connect the seaside village of Felixstowe with the Great Eastern system has just been opened to the public, having been surveyed by Captain Tyler on the part of the Board of Trade. The new line differs from all others in England in being the property of a single owner, Col. Tomline, formerly M. P. for Grimsby, who has not only constructed it at his sole cost, but is also working it himself, with his own engines and rolling stock. The line is 14½ miles long, and joins the Great Eastern at Westerfield, about 10 minutes' run from Ipswich. The line presents no engineering difficulties, running almost on a level throughout, and on a dry and easily-worked soil, so that it has been completed within 20 months of its commencement. Until very recently it was intended to be worked by the Great Eastern Company, but this arrangement could not be carried into effect, and the new engines and rolling stock have been built by the Yorkshire Engine Company, and delivered in eight weeks from the receipt of the order. Putting aside colliery lines, it is believed that the only other example in the United Kingdom of a line of railway owned by a single proprietor is furnished by one section of the Highland railway, which belongs to the Duke of Sutherland. But this piece, although it is his Grace's property, is worked by the Highland Company, and is continuous with the other sections of their lines, in which its identity is merged, or almost lost. Col. Tomline stands alone in having a railroad which is not only his property, but also under his control. He has spent, it is said, a quarter of a million sterling in the undertaking. Mr. J. Babington Macaulay, agent to Mr. Edward Cropper, writes to the *Times*: "Perhaps you will allow me a small corner of your influential columns to correct the paragraph referring to ownership of passenger railways by single proprietors. The Maelochog railway, now working into the heart of North Pembrokeshire, and terminating at his slate quarries, a few miles from Fishguard, is the entire freehold property of Mr. Edward Cropper, and worked entirely by his servants, engines and rolling stock, for both passenger and goods purposes. As regards public spirit and enterprise, there is strong affinity between the two cases in point; but where Col. Tomline's efforts have led him through 14½ miles of dry and easily-worked soil to his goal, those of the other gentleman were met by deep rock cuttings and valleys, mountain and moorland, river and forest, in the course of nine miles of railway, forming a variety of difficulties and of scenery in such a short distance almost unparalleled."

Mr. J. Grover, M. Inst. C. E., also writes from 9, Victoria Chambers, S. W.: "As you have drawn attention lately in your columns to Col. Tomline and the Duke of Sutherland as individual proprietors of railways, I take the opportunity of stating that Col. Yolland, the government inspector, has finally passed the Hemel Hempstead railway, a line nine miles long, connecting the Midland and Northwestern systems in Hertfordshire, which has been constructed by me for a single proprietor, Mr. J. J. Barrow. The line has some heavy works upon it, and will be of great service to the district through which it passes; therefore I think the name of the gentleman at whose cost such an important local undertaking has been carried out deserves to be recorded among those to whom the public are indebted for useful public works of magnitude."—*Iron*.

Idaho Mines.

The *Owyhee Avalanche* in a recent issue says: One of the principal drawbacks to the success of mining operations is often found in the rivalry of feeling exhibited by parties in their desire either to get control and possession of property or figure in some position in connection with the management. Rival factions have their particular friends whom they are anxious to supply with places, and the ill feeling too frequently engendered by such contests has a demoralizing effect upon the progress and stability of the work in hand. This cause, combined with that of incompetent management, having been instrumental in the past in seriously retarding the progress of mining operations in this vicinity, it is to be hoped that every citizen interested in mining property and the welfare of the place, will do his utmost towards discountenancing dissensions. Idaho is entering upon a new era of prosperity we hope, and the men who have borne the brunt of misfortunes attached to past failures are those who have stood by us and remained with us, possessing an abiding faith in the great resources we have at our command. These are the men in whose hands the future welfare and management of our mines may be safely entrusted. Our citizens, generally, who have been compelled to make great sacrifices, growing out of past failures, have evinced their readiness to make heavy pecuniary concessions with a view to having work resumed on some kind of a fair basis, and these are the men whose wishes and opinions should be respected in such matters. Give us honest and efficient management, and a judicious development of the mines, and Idaho with moderate capital will, in a short time, take her place as the foremost mining region of the Pacific coast.

The Salinas Quicksilver Mines.

On Saturday a representative of the *Index* took a trip to the works of the Salinas quicksilver mine, located in the McLeod mining district, San Benito county. The mine is 14 miles from Hollister. It was located by Geo. Shriver in June, 1875. He formed a company and placed the number of shares at 40,000. The company was composed of people living mostly in and around Salinas. The first prospecting was done in August of the same year, but the first real work commenced in March, 1876, and has been continued without interruption ever since. There were two tunnels run and one shaft sunk in prospecting, in all of which good, well-defined ledges of antimony were found.

The "Delta" Tunnel.

Mr. Shriver satisfied himself where the best place was to commence to tap the lead at some depth, and accordingly began driving a tunnel which was named the "Delta." He found good indications of antimony from the start, and when in 100 feet struck the ledge. It was found to be well-defined and was from four to six feet wide. On the east side is a wall of talc formation and on the west a sandstone wall. The ledge dips east at an angle of about 40°. The tunnel was continued in 200 feet after tapping the ledge, the antimony continuing good all the way. Mr. S. now determined to sink a shaft. He came back to within 166 feet of the mouth of the tunnel, made a station and began to sink a shaft, which was sunk right on the lead and runs with the same incline. It has gone down through good metal all the way. At a depth of 40 feet the formation began to change. Where had been antimony now came cinnabar. Through the antimony there was no water, but with the cinnabar came water; slowly at first, but steadily as the formation changed came an increase of water. Mr. Shriver's courage was now doubled. His theory had been that at a given depth the antimony would disappear and quicksilver take its place. The shaft was continued down 53 feet after the cinnabar came in and at the bottom they had to hoist three buckets of water to one of ore. The shaft was a little over four feet wide, and the ledge was fully that thick and growing richer every foot it went down. It now became necessary to make a change of base. The company would either have to erect hoisting works and put on pumps of sufficient capacity to keep down the water or run a new tunnel to tap the shaft. Mr. Shriver had demonstrated that he had metal in paying quantities and that it was no longer an experiment. He was safe in continuing work. The company could still go ahead and do work to the value of \$20,000, and if no further developments were made, by taking out what they had in sight, ship and sell it, the mine would pay a dividend to the stockholders. It was decided that the best plan to open the mine was to run a new tunnel that would strike some distance below the bottom of the shaft. On the 20th of February of the present year work was begun on a tunnel which was called

The "Georgia."

Work has been pushed night and day ever since—three eight-hour shifts being run—and the candles have never been blown out except Sundays. Mr. Shriver has never allowed any Sunday work except once to keep the water down while sinking the shaft. On Saturday last the tunnel was in a little over 500 feet, thus having made a uniform progress of about 40 feet per week. It is calculated that the shaft will be struck in 600 feet, and thus 100 feet more will put the tunnel in. When in it will be 60 feet below the bottom of the shaft, and with no bad luck the 1st of July will see the tunnel completed and the connection made, when stopping will be at once commenced. Two men will be enabled to take out 20 tons of ore per day from the tunnel, whereas it would take seven men to do the same amount of work from the shaft and tunnel above. One of the main objects of the tunnel now being run will be to ventilate the mine. It will also drain it, which is a great desideratum, as there is now 30 feet of water in the shaft.

The Buried Cities of Central Asia.

It is said that an expedition for exploring the buried cities of Central Asia is being planned in British India. It is not impossible that treasures like those of Mycenae may be found in the sands of Mongolia. According to tradition, the tomb of Ghengis Khan, with the fabulous wealth it incloses, is to be found to the south of Lake Tabasun-Nor. The quaint old legend concerning this mausoleum asserts that within lies a man who seems asleep. Every evening a sheep or a horse is tied near the spot, and in the morning the animal has been eaten. In 300 years, say the Mongols, the sleeper will awake and lead countless hosts of his children to victory and dominion. The old story is said to be circulating more and more widely every year. Then the Mongols say that frequently the drifting sands disclose, here and there, gold and silver treasures, which they have a superstitious dread of touching. The buried cities under the sands of the Gobi are affirmed to be mines of incalculable wealth, guarded by gnomes and fearful spells, while all the deserts around the hidden ruins are peopled by myriads of howling ghosts. But if the cities really exist, it will take more than a garrison of ghosts to defend them against the curiosity and the greed of modern explorers.—*Journal of Chemistry*.

MECHANICAL PROGRESS.

Corrosion in Steam Boilers.

The Hartford Steam Boiler Inspection and Insurance Company continues its investigation into the causes of boiler explosions. Its report for the year 1876 has lately been issued. From the many causes of destruction and death which are described, we select a few points on corrosion: During the past year the company found 1,026 cases of external corrosion, 442 of which were regarded as dangerous; also 542 cases of internal corrosion, 131 of which were regarded as dangerous. The causes of these defects are various. Where boilers are bricked in leaks occurring up near the water line are not easily discovered, and corrosion may go on insidiously until the sheet is largely worn away. This defect, in its early stages, can only be discovered by careful inspection when the boiler is cold, and to do this the inspector must make a careful examination externally underneath, and if he discovers indications of corrosion, the brick wall should be removed and the boiler be very carefully examined at the point where the leak is supposed to be. We have found cases where the boiler was so badly corroded that the steam was kept in place mainly by the brick wall. This is not a very reliable method of confining steam under 60 or 80 pounds pressure. External corrosion is not uncommon in iron and coal mines, and iron works where boilers are frequently used with no covering over them. This is a very dangerous way to deal with boilers, and probably accounts for many of the accidents which occur in such places. In a neighboring State a boiler was corroded to the thinness of sheet iron where it rested upon a brick wall and had probably not been inspected for some years. It was little to be wondered at that it exploded, and much damage resulted, and several persons were killed. Internal corrosion results from entirely different causes, usually from some impurity in the water. The report gives an interesting case: The inspectors were called to examine the boilers of a tallow factory, which were supposed to be in fair condition, and were running at a pressure of 60 pounds to the square inch. An internal examination revealed the fact that the feed water was contaminated with the refuse of the works, and that internal corrosion was doing a dangerous work. The water was examined and found to be strongly impregnated with stearic acid. The condition of the boiler was such that it was condemned as unfit for use. The braces and stays were so corroded as to be of no use whatever.

When a weak or corroded spot is found in a boiler it should be carefully examined with reference to the best means of repairing. If the sheet is found corroded so thin that there is not strength enough to hold the rivets necessary in patching, the sheet should be entirely removed and a new one substituted. Or, if the defective spot is confined to only a portion of the sheet, the iron should be cut away until sound metal is reached, and the patch should be riveted thoroughly to the sound portions of the sheet, and the edges of the patch calked. In their anxiety to avoid delay and expense, steam-users often put on what is called a "soft patch." This consists of a piece of iron laid over the defective spot and held in place by bolts, making the joint tight with stiff putty, composed of white and red lead and a small quantity of fine iron borings. This method of patching is careless, often in the extreme. The bolts are held only by a thin portion of corroded sheet, and are liable to tear out at any time. Soft patches over fractures, where the bolts are held firmly by sound iron, are not so bad. This method, however, is not to be recommended.

A CUSHIONED HORSE SHOE.—The subject of horse shoes involves considerations which are well worthy of scientific investigation; and a shoe was given the attention of the Franklin Institute, at a recent meeting of that body. The following extract, taken from the *Journal*, will convey an idea of the device: The shoe is cast of malleable iron, of the usual shape of a horse shoe, having its lower face open, into which a slip of tarred rope is pressed (by hydraulic pressure of many tons), of larger diameter than the width of the opening; a range of prongs rises from the center of the cavity, which pierce the rope, thus uniting with the stress from the sides, hold the hemp firmly. The shoe partakes somewhat of the moccasin and also of the sandal; it absorbs concussion and retains friction, and embraces other conditions of fitness.

THE PLANIGRAPH.—An instrument for reducing or enlarging drawings, called a planigraph, has been invented by M. Marnet, of Versailles. It consists of a rule carrying two scales, which have different graduations, and are placed end to end in opposite directions. At the common origin of the scales is a needle about which the rule can freely turn. Reading on one side the vector radii of the different points of a given figure, and marking on the other side the points designated by the same numbers, you obtain a figure reduced or enlarged in the proportion resulting from comparison of the scales. These scales are fixed to the rule by screws. There are five for each side, among which choice is made according to the reduction required.

Charcoal for Gunpowder.

Some of our State gunpowder makers may be interested in the progress which the English are making in the preparation of their charcoal. At a recent meeting in London a paper was read "On an Economical Method of Manufacturing Charcoal for Gunpowder," by Mr. Geo. Haycraft, F. C. S., Assoc. Inst. C. E. By former methods of manufacturing charcoal for gunpowder it had been customary to use three retorts, side by side, heated by a furnace at the end. In some instances the gases had been utilized, but at the cost of having constantly to renew furnaces and brickwork setting, while in others the gases had been altogether lost by being allowed to escape either in a gaseous or condensed form. By the new method two sets of three retorts had only one furnace between them, and the flues were so arranged that each set had its own outlet to the shaft, which was controlled by a damper. The man in charge, by closing one damper and opening another, could utilize the heat for either set of retorts at pleasure. The gases evolved in carbonizing the wood were all collected in suitable flues, and used instead of coals for maintaining the heat necessary for producing charcoal. In practice it was found that a given quantity of wood would give off enough gas during carbonization to effect the carbonization of a similar quantity, or nearly so. In working, one set of retorts was charged with wood, and heated in the first instance with coal, and a portion of the gas given off from the wood. When about two-thirds of the gases in the wood were evolved no more heat was required, because enough was stored up in the surrounding brickwork to complete the carbonization. The surplus gas, therefore, was transferred to the other set of cylinders, which were now full of fresh wood, and comparatively cold. By the time the wood in the first set of retorts was converted into charcoal, and a new charge put in, the second set of retorts was able to spare its surplus gas, and so the process went on alternately day and night incessantly throughout each week. Therefore, after first lighting the furnace on Monday morning it was only necessary to keep the furnace bars covered with ashes, chalk, or other available rubbish. By the old method about one cwt. of coal was required each time the three retorts were charged, but by the new arrangement 56 pounds of coal would effect 50 burnings in six retorts.

Enameling Iron Ware.

The following, says the *Hardware Reporter*, are the methods and materials employed in the enameling of most of the iron ware—other than granite or marbleized iron—now in use in this country. One hundred pounds of calcined and ground flints and 50 pounds of borax, also calcined and finely ground, are intimately mixed, fused and gradually cooled. Of this 40 pounds are mixed with five pounds of potters' clay, and ground in water to a pasty mass. The vessel, first thoroughly cleaned by means of very dilute sulphuric acid and scoured with sand, is lined with a coating of this about one-eighth of an inch thick, and left to harden in a warm room. To this a new coating is next added, prepared from 125 pounds of white glass, free from lead; 25 pounds of borax; 20 pounds soda in crystals, which have been pulverized and fused together, these being ground, cooled in water, and dried. To 45 pounds of this, one pound of soda is added, the whole mixed in hot water, dried and finely powdered. A portion of this is sifted over the other coating while it is still moist, and then the vessel is dried in an oven at the temperature of boiling water. After this, the vessel is heated in a stove or muffler till the glaze appears, when it is taken out and more glaze powder is dusted on the glazed surface already in fusion. This enamel, it is stated, resists perfectly the injurious action of dilute mineral and vegetable acids and alkalis, and does not crack or scale off from the metal.

In Germany and France the following process is said to have lately come into use, more especially for enameling copper culinary vessels: Twelve parts, by weight, of white fluor spar, the same of gypsum, one part borax, are finely powdered, ground together, and fused perfectly in a crucible; when cold, this mass is again carefully ground to powder, made into a uniform paste with water, laid upon the clean metallic surfaces, dried and ground.

THE GREATEST WAR SHIPS.—English exchanges tell us that a bold advance in the construction of ironclad ships has been decided upon by the Italian government in respect to the two vessels which are to excel the *Duilio* and the *Dandolo*. The new ships are now begun, but it will probably be six years before they are complete. They are to be unrigged turret ships, propelled by twin screws. They are to be much larger than the largest ships in the British navy, and much faster, in addition to which they will be much more costly. The most powerful engines in her Majesty's fleet are those of the *Inflexible* and the *Dreadnought*, working up to between 8,000 and 9,000 indicated horse-power. But this enormous amount is to be at least doubled by the engines of the Italian war ships. According to the present conclusions, the armor will be steel, probably a meter thick, or fully half as thick again as the maximum armor of the *Inflexible*. What guns these colossal ships are to carry is as yet undetermined, but it is not unlikely that in ordnance as well as in other respects the forthcoming ships will transcend all predecessors.

SCIENTIFIC PROGRESS.

English Desires in Blowpipe Apparatus.

The English Society of Arts offers a prize of \$50 and a silver medal for the best set of blowpipe apparatus which can be manufactured and sold for about \$5. Competition is open until August 1st. Although it may not be within the convenience of our readers to compete for this reward, still it may serve as a hint to inventors to be told what the society considers desirable in such an apparatus. We read as follows: The apparatus must, at least, contain blowpipe, blowpipe lamp or candle, spirit lamp, charcoal or charcoal pistilles and holder, platinum wire, glass tubes closed at one end (matrasses), open glass tubes, platinum-tipped forceps, magnet, hammer and anvil, and four reagents, viz., borax, microcosmic salt, carbonate of soda, and nitrate of cobalt. These instruments and reagents, together with any others which may be thought desirable, must be packed in a box. It must be understood that the above list of apparatus, etc., is only intended to include such as are absolute indispensable, and it is expected that the set will contain additional instruments and reagents, the selection of which is left to the competitors. Special attention should be paid to the following points: 1. Solidity of construction; 2. Compactness and portability; 3. Facilities for packing and unpacking; 4. Number of useful instruments and reagents in addition to those mentioned. The society does not engage to give the prizes unless some apparatus appears to show sufficient merit, and some advance on what is now obtainable for a guinea.

NEW IDEAS UPON THE USE OF STEAM.—Steam at ordinary pressure, sent into saline solutions on which it has no chemical action, gives a rise of temperature that seems at first sight paradoxical, the temperature produced being always higher than that of the steam. *Nature* says that M. Muller, of the Berlin Chemical Society, has been studying the phenomenon. Chloride of sodium is one of the best salts to use. A solution of it sufficiently concentrated to have a boiling point of 127° may be raised to 125° simply by sending steam into it at 100°. Here, then, the steam produces a rise of 25° above its own temperature. The more concentrated the solution the higher is the rise. M. Muller points out, in explanation, that saline solutions at 100° absorb the steam at the same temperature, and the result is a rise analogous to that produced when a gas, like ammonia, is dissolved in water. These experiments throw new light on the controverted question, what is the temperature of the steam which escapes from a concentrated and boiling solution? Is it 100° or a temperature near that of boiling of the solution? The new results seem to be against the latter and common view.

NO LIMIT TO MICROSCOPIC PROGRESS.—As we have formerly remarked, Helmholtz and other mathematicians of the first order who have applied their methods of analysis to the subject, have alleged that the limit of visibility with the microscope has been reached. This belief is based on the theory that light itself is too coarse to permit the subdivision by which yet smaller objects may be revealed to our most powerful lenses. The limit of visibility has been named as the 180,000th of an inch. But this view is not wholly accepted by microscopists. The Rev. Wm. H. Dallinger has made experiments which point to a very different conclusion. He employs a new method of practical observation specially adapted to testing this question, and has constructed lenses which carry the limits of distinct visibility far beyond the boundary announced by the mathematicians. Much smaller objects are thus revealed than the theory referred to would indicate as capable of being seen. Furthermore, Mr. Dallinger does not believe that he has yet reached the limit of division and visibility by instrumental means.

A CORAL CURIOSITY.—A Melbourne journal describes a remarkable piece of coral taken from the submarine cable near Port Darwin. It is of the ordinary species, about five inches in height, six inches in diameter at the top and about two inches at the base. It is perfectly formed, and the base bears the distinct impress of the cable and a few fibers of the coil rope used as a sheath for the telegraphic wire still adhering to it. As the cable has been laid only four years, it is evident that this specimen must have grown to its present height in that time, which seems to prove that the growth of coral is much more rapid than has been supposed.

AMERICAN ASSOCIATION MEETING.—The 26th meeting of the American Association for the Advancement of Science will be held at Nashville, Tennessee, on August 29th. Sessions will take place in the Capitol. Special arrangements are being made for decreased railroad fares, etc., and for the accommodation of members in the city. The permanent subsections of chemistry, microscopy and anthropology are to be continued, and the co-operation of students of these sciences is requested. The Entomological club will meet on the day preceding the meeting of the association.

ELECTRIC LIGHTING.—One of the late English improvements in the application of electricity to lighting, promises to enable us to admit the lightning to our houses. We read that a novelty has been introduced which consists in placing the carbons side by side in an insulating but fusible envelope, the result being that clockwork regulation can be entirely dispensed with. The insulating material used is kaolin, which, in its solid state, is an insulator, offering high resistance to the electric current, but which, under the influence of a powerful electric current, becomes heated and liquefies, in which state it is no longer an insulator, but conductor, offering a slight resistance to the current, which, when passed through in this condition, affords a light which is soft, steady and brilliantly white, although it may be colored by mixing with the kaolin the color required. No mechanism is required to regulate this light, which, once set up, continues to burn during passage of the current until the carbons are consumed, when they are replaced by others. The electrical arrangement consists of an ordinary magneto machine, which sends positive and negative currents alternately. From this machine radiate wires by which the current evolved is conveyed to the buildings or points at which it is required for use. The illuminating arrangement is put in circuit with these wires, and on the current traversing the carbon electrodes it fuses the kaolin and produces the light. Thus, given a means of producing the necessary electric current, any number of lights may be obtained from the same electro-motor, each dependent upon itself, and all entirely independent of each other. Any one light may be brought into use at pleasure, and extinguished when required by merely connecting or disconnecting the wires in connection with them, whilst a light consumed may be replaced by another with equal ease. As many as 50 lights have been set up in one circuit with success.

GLASS FROM SLAG.—We have already noted the English process of manufacturing glass from blast-furnace slag. We learn now that the process consists in using the slag in its liquid state direct from the blast-furnace. It is found that the whole of the slag when thus employed is convertible into perfectly transparent glass of a good color. The slag, while in a liquid state, is conducted into a tank holding about 15 cwt., where it is mixed with other materials, and in an incredibly short space of time, as compared with the ordinary method, glass is produced. This glass is acknowledged by the workmen to be of an exceedingly soft or plastic nature. It is perfectly acid-proof, and capable of use for all purposes for which the best bottle glass is suitable. It cuts readily with the diamond, and is available as rough plate for roofings, skylights, green-houses, roofing tiles, and for many other uses from which glass, as heretofore manufactured, is, on account of its cost, necessarily shut out. Specimens have also been produced of this glass colored brilliantly, and suitable for the purposes to which colored glass is employed.

A REMARKABLE MONUMENT.—The Department of State at Washington is in receipt of a letter from Gen. John Meredith Read, Charge d'Affaires at Athens, reporting the discovery by M. Stephen Commanderis, the leading Secretary of the Archaeological Society of Athens, of the monument mentioned by Thucydides, as having been erected by Pisistratus, son of Hippias, and grandson of the tyrant Pisistratus. The stone, which was lying neglected on the right bank of the Ilissus, southwest of the temple of Jupiter Olympus, bears an inscription, of which the following is the translation: "This monument, upon his advent to power, Pisistratus, the son of Hippias, has dedicated in the Temple of Apollo Pythius." The discovery of this remarkable stone fixes the site of the temple of Apollo Pythius, which was hitherto unknown. The monument has been purchased by the Archaeological Society, and will be immediately transferred to the museum of Varvakion.

AN ANCIENT CALENDAR.—In digging near Ceri, Rome, there has been discovered a superb marble fragment of an ancient Roman calendar, containing the second half of the first five months of the year. Beside the usual indications of days, feasts and the different games, there is a list of the principal solemnities; some of these last are quite new; others confirm conjectures which have been made by learned men on less certain indications. The most recent date which can be read is that of the dedication of the Altar of Peace by Augustus in the 745th year of Rome.

RESEARCHES.—Forty-five scientific expeditions were fitted out during the year 1876. Of these, 24 had their field in Europe, seven in Africa, five in America and two in Oceania. The objects of the researches included archaeology, natural history, anthropology, medicine, statistics, comparative legislation, comparative history of religions, philosophy, geography, geodesy and astronomy. In addition, organized researches were also made among archives and in libraries.

A BESSEMER STEEL BELL.—The *Bethlehem Times* says, probably the first Bessemer steel bell ever cast now hangs in the belfry of the Presbyterian church, in that borough. This bell was cast in the Bessemer works of the Bethlehem Iron Company and weighs but 58 pounds. Its tone is clear and pleasant.

MEETINGS TO BE HELD.

NAME OF COMPANY.	LOCATION.	SECRETARY.</
------------------	-----------	--------------

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

California.

AMADOR.

MADONEY.—Amador Ledger, June 23: Mining operations on this property are at a standstill. A dispute has arisen concerning the control of the mine, which is likely to be taken into the courts.

MONTICHRARD.—The result of the crushing of Monticrhard ore at the Onoda mill is very satisfactory. Twenty stamps reduced 300 tons of rock to pulp, and the clean-up was made early last week. The yield of bullion averaged \$5.50 per ton—a very satisfactory showing taking all the drawbacks into consideration. A quantity of gouge water was passed through the mill, which materially reduced the average yield. The mill-man is of the opinion that had the crushing comprised nothing but clean ore, the yield would have reached as high as \$13 or \$14 per ton. At any rate, the paying character of the rock is now established beyond dispute. The loss of the mine and the ascertained richness of the quartz ought to induce the managers to prosecute mining operations hereafter in a thorough business-like manner. Although \$8.50 per ton is considered an excellent yield by mining men, still that sum no more than covers the actual expenses of mining and milling as things have heretofore been conducted at the Monticrhard. Negotiations are pending for the sale of the property to San Francisco capitalists.

GOVERN.—Everything moves along prosperously at the Governor. Twenty stamps are kept running, crushing at the rate of 35 tons per day. The mill is supplied from the stopes of the 700-ft level, where the ore vein is 25 feet in thickness, and every pound of the rock is milled. It is a sufficient demonstration of the auriferous wealth of the ledge to say that the last three clean-ups have panned out \$15 per ton. One and a half tons of sulphurets are saved each day, which assay from \$120 to \$150 per ton. The hoisting works are running satisfactorily. The new shaft is down 230 feet. Work is also being pushed upward from the 500-ft level to connect with the new shaft. At mine and mill steady employment is given to 56 men.

BUNKER HILL.—This mine looks better to-day than at any previous period of its history. The shaft reaches 350 feet, at which depth the ledge shows four feet thick, and extends 90 feet in the cross-cut to the eastward. The good ore is this week, the vein averaging three feet in width. Eighteen tons of quartz are put through the mill daily, paying \$13 per ton. Twenty-three hands are employed.

BONANZA.—Shaft down 270 feet in paying ore. There is enough rock in sight to keep the mill going for months.

NICHOLS GRAVEL CLAIM.—This mine is located half way up Butte mountain. Owing to the pitch of the bedrock it has been found necessary to start a new tunnel, about 40 feet lower down the mountain than the old workings. Workmen are now pushing ahead with the tunnel, and expect to strike the channel at a distance of 40 or 50 feet.

DAYTON'S SULPHURET WORKS.—Garland's new sulphuret works at Drytown are to be started up the first week in July. J. B. Phelps got through building the ovens last week. Ninety tons of sulphurets from the Governor mine are already on the ground awaiting treatment.

The canal company are laying piping from the canal over Kennedy hill with a view to supply the Kennedy and Monticrhard mines with water.

CARL BECK is running a tunnel into a hill at Hunt's gulch, prospecting for gold.

The water in the Amador canal loses much of its volume by leakage and evaporation in passing from the head of the ditch to the reservoir. The supply will not more than satisfy the demands of the quartz mills during the summer.

THE LOYAL LEAD COMPANY, whose works are near the Governor, have abandoned work. The property has been attached by the miners for \$2,000.

PHENIX.—It is said that the prospect in the Phenix is so good that it is considered certain that the Alpine mine will start up in a short time. Plymouth is a live place, and her citizens are not to be crushed by one destructive fire. We learn that the Phenix mill will shut down the first of next month, and all the hands who are not wanted for the sinking of the two shafts will be given work on the ditch. The company have decided to enlarge the ditch from Plymouth to the Consummes river. They will also raise the embankment on the reservoir 10 feet higher and cut the race at the mill 10 feet deeper, so as to increase their motive power.

CALAVERAS.

CLEANING UP.—Calaveras Chronicle, June 23: Emerson, Veith, Moser & Co., and Cook & Co., all noted hydraulicists, are cleaning up and will get through next week. Emerson, we believe, has finished. In our next issue we hope to be able to unfold a tale relative to mineral wealth that will even astonish the natives.

NEW PUMP.—A new pump is to be put into the Chapman mine of Railroad, the one now in the shaft being incapable of keeping the mine free of water.

UPPER COUNTRY BELIER.—Eight tons of ore taken from the mine belonging to Monsieur Monson, at West Point, yielded an average of \$45 per ton. Good ore continues to be taken from the Lacey tunnel. Champion, sinking and stopping. Zacetero mill not yet ready to start. All the other mills in the district are in active operation.

EL DORADO.

RICH YIELD.—Mountain Democrat, June 23: At the Church-Union mine, near Logtown, this county, a clean-up was made on the 1st inst., after a ten days' run, and \$3,200 realized. On the 15th, after a 12 days' run, there was another clean-up of nearly \$5,000. At the point of present working the show is good and strong, and the ore averages about \$35 per ton.

HUMBOLDT.

NEW RIVER.—Eureka Star, June 22: B. P. Parker, Percy Parker and Henry Parker, all sons of the late B. P. Parker, are about to start a new mine on the New River. They will take with them a stock of goods for the purpose of establishing a trading post in the mines. Enough has already been ascertained to make it certain that there are good mines in that section; but how extensive or permanent they are can of course only be determined by time.

INYO.

KEARSARGE DISTRICT.—Cor. Watsonville Pajaroner, June 21: In the last two or three years there has been some capital employed in developing the mines of this section, and with remarkable success. I know of one company—the Rex Montis—that was organized only about one year ago in San Francisco, to open a mine in the Kearsarge district, about six miles from Independence, the county seat of Inyo county. They bought three lodes or three distinct mines for \$20,000, gold coin, not, however, until they had prospected the mine enough to take out about \$13,000 in bullion. The ore from which this money was extracted was taken from but a single vein, and put through a 144 stamp mill in about 20 days. For the benefit of other corporations interested in the company is a private institution, keeps its own count and controls its own stock; they don't propose to place their stock upon the board for fear of its losing caste. As for the richness of these ores there can be no doubt. This same company sent 287 pounds of average ore to San Francisco, had it reduced, and got out of that amount of ore \$10,000. This ore came out of the Rex Montis lode. They also own two other lodes, the Arctic and Boomerang. They now propose to work the Arctic, which is thought by experts to be a richer mine than the Rex Montis, and in order to facilitate the work, they have set aside a few thousand shares which they will sell at the nominal price of \$1 per share. The money raised on these shares will be expended in taking ore from the Arctic, and all above the expenses of reducing the same will be paid to the holders of the shares. This heretofore much

neglected mining district, I am happy to say, is beginning to attract the capitalists. Since 1874 there has been business in this locality. Silver has been taken from the Surprise Valley quartz mills, at an aggregate cost of \$120,000, and many others are in course of erection.

PANAMINT.—Coso Mining News, June 23: Mr. John P. Du Bedat, Secretary and cashier for the Surprise Valley mill and water company at Panamint, came over from there last Tuesday and went below on Wednesday. He corroborated the reports of the strikes made in the Hemlock and Wyoming mines of that company at a depth of 650 feet, and says there is not a doubt but that active operations upon both mines will be resumed at an early day.

NEVADA.

NEW ENGLAND.—Nevada Gazette, June 22: The New England mine continues to pay liberally. The ledge is 18 or 20 inches in width. The last crushing at Keith's mill of 100 tons yielded something over \$80 to the ton, we believe. Another hundred tons was commenced on at the California mill on Wednesday. The rock from this mine has averaged over \$80 since crushing on it commenced. Few mines in the county can show a better record than the New England.

THE QUINN.—Nevada Transcript, June 23: A few days ago a wonderfully rich find in quartz was made near this place. Three men of Rough and Ready township, Grant, Reese and Early, were prospecting on the headwaters of Squirol creek, near the Brown Brothers' gravel claims. A lot of float quartz was found, and it showed well in free gold. Grant and the others began to search closely, thinking that there must be a rich ledge in that vicinity, and the result was right. A ledge has been found that is immensely rich in the brightest and heaviest kind of gold. They have sunk a hole about seven feet in depth, and from that about 800 pounds of quartz have been taken. All the rock is filled with gold, and good judges say that these men have not less than \$20,000 worth of the precious metal in that 800 pounds of rock. The location where this "find" exists has always been famous for nuggets, but regular ledges, that pay well, do not seem to be found there. The boys are certainly in luck. One of them, Reese, made a big find two or three years ago on Randolph flat.

HOWARD BOUND.—Foothill Tidings, June 23: All the machinery is set and everything in good trim about the new shaft. The consideration of proposals for sinking the shaft is now going on, the work to begin on Monday. The ledge in the bottom of the shaft—15 feet below the old level—looks better than ever before, and a big strike may be looked for any day.

YUBA RIVER.—This, the pioneer among the new river mining enterprises, is progressing very favorably, considering the entire novelty of the work, and therefore lack of definite knowledge as to the rock likely to be encountered. The drift has been going through very hard rock, but is said to be in better ground now. Water was still coming most at the face of the tunnel, which has caused the continuance of the drift further in than was intended—the channel evidently being still ahead. Much, very much is depending upon the result of this trial, and much anxiety is felt all through the country. Yuba owners all feel sanguine of success.

PLACER.

REMINGTON HILL MINES.—Dutch Flat Forum, June 21: The Rhode Island company have turned out and are cleaning bedrock, which is said to be paying splendidly. The Wide West company is opening two breasts east of tunnel No. 2, where the gravel is found to pay \$20 per ton to the man, consequently but one of the main tunnels is being advanced at present, which is also said to be paying well.

LOWELL HILL MINES.—Work in the Swamp Angel continues to be prosecuted with energy and skill. The payment of which is the disbursement of monthly dividends. Their supply of water is taken from the Little York company's ditch, and as the latter company will require all of it themselves during the balance of the season, the Swamp Angel company are making preparations to build a large tank or small reservoir, which, when completed, will enable them to catch a sufficient supply of water from the springs to wash in the future. The contract for running bedrock tunnel in the Placer gravel mine was awarded to S. S. Shaffer & Co., and the work of extending the same is now progressing day and night. The running of the Wild Cat tunnel has been incubated considerably of late by encountering a large vein of serpentine rock, and in passing through it, it was found necessary to timber it closely with heavy posts and caps, also using skills. The work is now progressing under favorable circumstances, with the expectation of tapping the channel next month. The various other channels being run in this vicinity are said to be making good progress. The Liberty Hill company continue to wash steadily, and the progress made in removing the many boulders encountered is said to be astonishing.

LITTLE YORK MINES.—The Empire company turned off and cleaned up last week, giving satisfactory results. They are now running a powder drift, which will be completed, charged and exploded in one week, when washing will be resumed again.

CLOSING DOWN.—The continued warm weather has affected the water supply in the various ditches and the quantity is gradually diminishing. Most of the claims in this section are drawing their operations to a close for the season. The Star and Union and Baker claims continue washing, as last reported. It is the expectation of the Superintendent to keep these claims washing for some months yet. The latter is making good headway, and has removed nearly all the material loosened by the large blasts, all of which will probably be washed off by the 1st proximo. Powder drifts are nearly completed, extending back into the hill about 100 feet beyond the shaft. It is supposed the next blast will open the pit into softer gravel, which will be a great relief to the channel next month. The Franklin is working and washing, using water a few hours each day. The Polar Star and Southern Cross have been kept constantly at work, one using the water while the other is removing the boulders. The Elmore Hill claim is washing again. It has been off a number of days preparing and exploding another blast. The Pacific is idle, owing to the scarcity of water. The claim of the Illinois is being cleaned up, but is to have turned off this morning, to clean up for the season. The Bonanza and Sachs claims are still washing. The North Star will run a short time longer, when it will wind up. The Illinois has made its final clean-up for the year, after a very successful season. This claim has proved to lie in quite a rich piece of gravel.

SHADY RUN MINES.—The Wild Yankee company turned off and are making a general clean-up. The channel bedrock the crevices are found to be very rich, as high as \$75 in specimens having been taken from one. The North American company, in extending their main tunnel 300 feet farther through bedrock, tapped an extensive channel, which is said to be paying well.

BLUE CANYON RAVINE MINES.—As the work progresses in the Roaring Blunder the indications for an extensive channel are favorable, and the drift is being washed, and is very rich. Several other claims have been taken up in this vicinity recently, and there is considerable prospecting being done.

PLUMAS.

CRESCENT.—Plumas National, June 23: Supt. Jewell, of the Crescent Plumas, says that the well, which reports everything flourishing in his neighborhood. He says the work underground daily shows better, and the fact that the company have a permanent mine and a good one is established beyond a doubt. We are glad to record the good prospects, and hope they may "increase and multiply."

SANTA CLARA.

THE GUADALUPE QUICKSILVER BONANZA.—San Jose Mercury, June 22: The new developments on the 600-ft level of the Guadalupe quicksilver mine, in this county, are proving of such an extensive and permanent character that Supt. Thayer has determined to sink the main shaft 500 feet deeper, or to the depth of 1,100 feet. The work will be commenced at once, and pushed forward as rap-

idly as possible to its completion. The shaft has three compartments, one of which is used for the pumps, and the two others for the regular hoisting business of the mine. The machinery is ample for any depth of shaft. A winze is being sunk on the newly-discovered ore body, and the construction of lower levels is necessary for the economical working of the mine.

SIERRA.

HETTER.—Mountain Messenger, June 23: We had not supposed it possible to find any richer rock than had already been taken from the North Fork, but we learned yesterday that the richest rock yet struck in that claim was found the night before. This bids fair to be the richest claim ever found in this State.

CURRY CANYON.—Some Chinamen on Kanaka creek recently brought to Forest City a piece of solid gold weighing 30 ounces.

WATER WHEEL.—S. D. Hill is putting a water wheel in the river below his claim on Dargan flat. He has a large crew of Chinamen working there, and the ground pays well.

DITCH.—Geo. Cox has purchased Dr. Mussey's ditch and claims at Gibsonville. The ditch will be immediately commenced and used by Mr. Cox. Goarly will superintend the work.

COLD CANYON.—McFarland and McNece are working nine men in their diggings, the old Sierra claim, and more men than paying expenses. Hope they will do well.

SISKIYOU.

LOOKING AT THE MINES.—Yreka Union, June 23: During the past week two different parties have been in Yreka from San Francisco looking at our mines. The first party, Messrs. Holbrook and Richardson, went over on Humbung with Jas. Quinn and Wm. McConnell to look at a claim at the mouth of Humbung, owned by the latter parties, and being well satisfied with it at the price asked, they made arrangements to buy it at a set price, or put up the machinery necessary for the proper working of the claim, in consideration of half of it. They then went to Happy Camp, and calculate to return below to-day. It is not known positively what the other party, Messrs. Bowie, Farrish and Whitaker, are after, but it is generally supposed that they are looking at the Yreka creek property. We are glad to see these gentlemen among us, for they are men of business, and there are plenty of good mines here that only await the capital necessary to open them, to prove themselves such.

SONOMA.

THE COAL PROSPECT.—Sonoma Democrat, June 23: C. W. Frost, Supt. of the Santa Rosa coal mine, informs us that the prospect is most encouraging. The main tunnel has been run into the hill 100 feet, and an incline has been sunk from the end of this tunnel to a depth of 60 feet. At this depth they have a vein of coal-bearing matter eight inches thick, through which seams of excellent coal run. This is considered very encouraging.

TULARE.

MINERAL KING MINES.—Cor. Visalia Delta, June 23: Here, preparations are being made to start up the furnace. The snow has left the valley, but is coldly abundant on the mountains all about. The assay building is well under way, and will be completed soon. President Baker went to Visalia yesterday, and expects to return this week with the assay outfit that was sent from San Francisco. Work has commenced on the Empire, and the tunnel claim above here. Three tons of the finest ore was roasted for 48 hours in the furnace. A lack of chemicals for making necessary assays prevents further intelligent experimenting until the arrival of the remainder of the assay outfit. A few of the claim holders are working out their assessments, a few are prospecting, all expect to go to work soon.

TUOLUMNE.

THE SWEENEY MINE.—Tuolumne Independent, June 23: Active operations have commenced on the Sweeney mine, Quartz mountain. Mrs. Hill, the owner, has let a contract to sink 100 feet deeper. The shaft is now down 90 feet, and the last rock taken from this point milled \$26 per ton. This is undoubtedly one of the best mines in the county, and it only needs development to prove its true worth.

Nevada.

WASHOE DISTRICT.

CROWN POINT.—Gold Hill News, June 27: The south drift from the main east drift on the 2000-ft level is being forced rapidly ahead to reach and connect with the Crown Point-Belcher drain shaft. This drift is being run easterly, outside of and west of the ore vein.

UTAH.—The south drift on the 1150-ft level, running to connect with a like drift from the Sierra Nevada, is being forwarded with all energy possible, the face in a fine character of quartz and ledge matter. The prospects of the Utah are steadily brightening.

CROWN POINT.—Daily yield, 110 tons of ore, the assay value of which is \$25 per ton. During the first part of the week a streak of somewhat softer rock was struck in the bottom of the combination shaft, which, however, was passed through in a few feet, and yesterday the bottom was again in rock so hard that it rings when struck, like metal.

WEST BELCHER.—Work is resumed in this mine under the most favorable auspices. All the indebtedness of the company is being paid off, and under the superintendency of Mr. William Lee the works are being started up and the explorations and development of the mine will be proceeded with.

SUCCESS.—Sinking the main shaft is being pushed ahead with all the force that can be brought to bear. The Success mine has never in the past been worked in a manner so favorable to the owner, as the payment of the regular LEVIATHAN cross-cutting gas from the south drift at the 600-ft level is suspended, and drifting south is continued, with the face of the drift principally in quartz, carrying streaks of low grade ore.

CON. VIRGINIA.—Daily yield, 550 tons of ore. The mills are kept steadily running, and the yield of bullion for June is already \$100,000 in excess of the yield for the five months preceding. The payment of the regular dividend of 8¢ per share, and will leave a surplus to be carried over to the next. The mine is looking splendidly at every point, and the ore breasts show no signs of exhaustion. The ore stopes on the 1650-ft level continue of the finest character. The bottom of the joint winze below the 1650-ft level is still in fine ore. It is now down 42 feet. The east drift from the south winze on this level is still being pushed ahead, and is said to be of the best quality. On the 1550-ft level the main south drift connecting with the Gould & Curry is being rapidly enlarged. Two winzes have been started on this level to penetrate to the 1650-ft level and assist in the better ventilation of the mine. On the 1400-ft level the ore stopes continue their regular yield of rich ore. The south drift from the shaft on the 1800-ft level has completed the connection with the No. 5, which is entirely east of the ore vein, greatly assists the ventilation in that portion of the mine. Sinking the C. & C. shaft is steadily progressing. The huge new air compressor is nearly completed, and will be ready to start into full operation in a day or two more.

CALIFORNIA.—Daily yield, 600 tons of ore. The ore stopes and breasts are showing splendidly at every point, and the ore is being shipped to the coast. The mine is richer than it is to-day. The 1650-ft level is opening up rich in almost every quarter, and the double joint winze now being sunk near the south line of the mine is now down 42 feet, the entire distance having passed through rich ore. On the 1600-ft level the stopes continue to look well and yield rich ore. The several winzes now being sunk below the 1600-ft level are in ore, with the exception of the No. 5, which is entirely east of the ore vein. The yield of bullion is already \$200,000 in excess of the yield for May, so that the payment of the regular dividend of 8¢ per share is an assured fact. The mills are all kept running at the very top of their speed.

YELLOW JACKET.—The main drift east, cross-cutting the ledge at the 2200-ft level, is now in 126 feet and still continues in bird's-eye porphyry, hard and dry. The south

drift at the same level is in 130 feet in somewhat softer material, with small streaks of quartz running diagonally across it to the southeastward. The new working shaft, to the eastward is now down 766 feet. There is no decrease of the heavy flow of water encountered.

OVERMAN.—The main east drift on the 1300-ft level is being steadily driven forward. The ledge at this point has great width, this drift having already penetrated the ore vein a distance of 300 feet, with no indications whatever of being through it.

OPTIMA.—Daily yield, 40 tons of ore, keeping the Winfield mill running and crushing to its full capacity. The main incline is down 44 feet below the 1900-ft station, and is being continued downward to increase the capacity of the pump in case water is struck on the 1900-ft level.

KEYSTONE.—This mine, although an old and valuable location, lying just north of the Utah mine, has for a long time laid idle on account of the impetuous condition of the owners. A short time since the control, however, passed into the hands of able capitalists, who, on the 11th of this month, commenced its development in a manner commensurate with its worth.

LADY WASHINGTON.—Work is resumed in this mine. The machinery being overhauled and put in complete order, the water is being raised from the shaft.

COX.—The prospecting drifts, both north and south, from the station at the bottom of the winze below the 1300-ft level, are making steady progress.

JULIA.—The main south drift on the 1800-ft level is steadily advancing, the face still in quartz and ore. The prospects for pay ore in this drift are better than they have been at any time in the past.

SAVAGE.—The pumps are gradually gaining on the flow of water, which is now reduced to a point 100 feet below the 1200-ft level.

BULLION.—The drift north at the 1700-ft level continues advancing in favorable vein matter.

BECHER.—Daily yield, 65 tons. The face of the east drift at the 1600-ft level continues in quartz and porphyry. At the 1600-ft level the east cross-cut from the main south drift is in 223 feet and still running in low grade ore.

DAILY YIELD.—Daily yield, 450 tons. The various ore-producing sections are yielding and holding out finely. The winze being sunk below the 800-ft level continues in very fine ore, and the excellent ore developments at the 1000-ft level are showing better and better as further advanced.

MEXICAN.—The drift north at the 1465-ft level to connect with the drift south from the 1450-ft level of the Sierra Nevada, is advancing favorably in good working material.

SIERRA NEVADA.—At the 1600-ft level the south winze is sinking in very favorable material, with considerable quartz, and the face of the south drift is in good looking vein matter.

GOULD & CURRY.—Sinking the main incline is resumed. The winze being sunk below the 1800-ft level has reached the 16-ft level, and drifting north and south from it toward the Best & Belcher and the Savage is being commenced.

SILVER HILL.—At the 650-ft level the drifts both north and south are driving ahead lively.

NEW YORK.—The repairs to the drifts at the 800-ft level both east and west are progressing, and the pump stations in the shaft are about completed.

HALE & NORRIS.—The water is being steadily reduced in 100 feet below the 800-ft level. The incline below this point is found to be filled with debris from the old cave.

SUTRO TUNNEL.—Very good advancement is now being made in this elongated tunnel, one of the longest in the world. The header is running through regular ledge matter, composed of hard porphyry with streaks of quartz and clay. This material blasts well and allows of a good rate of progress.

W. P.—Preparations are being made to soon resume both the sinking of the shaft and the south prospecting drifts on the 1600 and 1800-ft levels of the Julia mine.

Arizona.

NEW MILL.—Arizona Enterprise, June 20: The Turkey creek mill has reached the Point of Rocks, eight miles east of town, from which place it is the intention to haul it by ox teams to its destination.

THE PECK COMPANY have decided to move the Aztlan mill to the mine. The requisite machinery to put the old mill in first-class order has been ordered.

In Hasavampa district a great deal of steady work is being done at present, and the yield of dust and bullion which is finding its way to Prescott speaks convincingly of the richness.

Many other quartz claims are being worked in this district and all are looking well. The facilities for mining in this part of Yavapai county cannot be surpassed by any camp in the Territory.

Among the courses of the Hasavampa placer miners are all at work and doing well. Although this creek has been worked for over 12 years, it still keeps up its well merited reputation.

In Walnut Grove district the situation is most promising. A five-stamp gold mill is now on the way, and will be erected on Arastra creek.

In Mohave county mining affairs are about as last reported. The yield of bullion is steadily on the increase, and the opening of many new claims is giving a look of assured prosperity to the numerous camps in this rich mining region.

In Maynard district, Mr. Shoultes on the American Flag is taking out rock as rich as any that has ever been taken out in the country. He has now ready for shipment 14 tons which sample \$2,000 per ton. This is hard to beat in any country. The other claims in the district are all showing well and turning out their regular quantity of ore.

From the Sandy country we learn that the new mill brought on by Mr. Leet will shortly be up and in running order. With 30 stamps in this camp we expect it to take the lead in the bullion yield of the Territory. But a hundred stamps would not be enough to reduce the ores from the wonderful McCrackin.

Desamoy work is now the order of the day. What the miners of Arizona long prayed for—mills for the reduction of their ores—are now here; they will help the cause much more than the empty talk of so-called capitalists.

Idaho.

MINING NOTES.—Owyhee & Valance, June 23: The most important movement pertaining to the mining prospects of this vicinity is the contemplated sinking operations in the Golden Chariot, the arrangements for which have been completed, and the work, we understand, will be prosecuted with as little delay as possible. This is cheering news, and the value and importance of such a movement cannot be overestimated at this particular time. By sinking 200 feet and driving the prospects to extract the ore, a life insurance will be furnished of the future prospects of this mine and the grand outlook that is in store for old War Eagle mountain, whose treasure leads, notwithstanding they have turned out millions of wealth, have as yet scarcely been tapped. No movement yet undertaken in this camp can possibly give a greater impetus to work along the whole line of this immense lode and improve the prospects of the O'Fino and South Chariot, which two mines alone under skillful and judicious management can be made to turn out enough rich and paying ore to supply the milling capacity of the camp. The character of the developments on the 13th level as far as prosecuted fully justifies the most sanguine expectations pertaining to the existence of the bonanza so clearly outlined in the prospect of the O'Fino and South Chariot, which will revive the hope of all interested in the camp. The recent work outside of the main vein has been attended with the most satisfactory results. The large amount of bullion produced from working the lateral and parallel fissures, extending from the third to the seventh levels, and converging in the Chariot, prove conclusively the existence of the great lode of the mountain in this vicinity.

The Old and the New.

Thoughts for July Fourth.

[It is according to usage to contrast the past and present each time the National Holiday comes round. Seldom are thoughts of this kind more truly and pleasantly expressed than in the following lines of Benjamin F. Taylor:]

The world stood still for a thousand years
And crept for a thousand more,
This wonderful world with wings for ears,
Like the Messenger god of yore—
And winged feet and winged wand,
And a wing on its either hand,
And more than Mercury wore.

It bridle and rides a furnace's foal
With iron and hammer for sire,
Great clouds of white from their nostrils roll,
And it feeds its horses fire!
They are blooded stock, the engines swift,
Beneath their heels the distances drift
Like snows from the Arctic Pole!

They rattle across meridian lines
And down the parallels play,
They marry together the palms and pines,
A thousand miles in a day!
The world has trained a wonderful wire,
A nerve of a route for articulate fire,
And taught the lightnings to say:
"Dear Mary, be mine!"—"Carload of swine"—
"One ton of cheese!"—"Maria dead!"—
"Joy! It's a boy!"—"I'm coming to dine!"—
"Send soap!"—"She's married to Fred."
The humblest of words like angels fly
A thousand miles in the flash of an eye,
You hear before they are said!

What's happened at ten you know at nine,
And you away in the West,
They distance along the lightning line
The sun in his golden vest
They talk to-day in audible tone,
The telegraph turns the telephone
And parted lovers are blest!

Think of a girl in a lonely hour,
No beau in a forty miles,
She sits by the tube of talking power,
She thinks a minute and smiles.
"I'll call my John," you fancy her to say,
"He lives but a hundred miles away,
And banish the weary whiles."

Behold them at the ends of the line,
This John and his black-eyed boon,
His head and hers to the wire incline
And she sings him "Bonny Doon."
He sighs for the only thing amiss,
He has a voice but then he can't—kiss!
He might as well be in the moon!
For emptier than an East wind's laugh
Is a lover's kiss by telegraph!

The old world rocked the harvests to sleep
And cradled the drowsy wheat,
The scythes that went with a rasping sweep
As they mowed their narrow street,
And the new-moon knife they used to reap—
Sickle and cradle and scythe and all
Are hid in the garret's rafters hall
With cradle for twins when they dared repeat—

Hid with the bonnets of Leghorn flare
And the distaff's head of tow,
The old foot-stove and the rush-wrought chair,
And bell-crowned hats of the ancient wear,
The warming-pan and the little wheel,
The dusty ghost of a clock-tick reel
And the trundle bed so low.

It hid by day 'neath the family bed,
A chicken under a hen!
I love the wrecks of the days long dead,
The times of the home-spun men;
I love to think of the hearthstone fire
That opened its heart like a large desire,
And room at table for ten.

The swift world reaps with a tireless thing
And mows with a hundred knives,
Of the golden year legitimate king,
And the strength of a hundred lives!
They rout the wheat and they wreck the grass,
Like whirlwinds come, like whirlwinds pass,
They hurl the grain like creatures of wrath
And hustle the harvests out of their path,
A slash, a toss and a fling!

Torrents of grain and tempests of chaff!
The thresher comes in its might,
Crunches the straw with a grate of a laugh,
Clouds like the thick of a fight—
A thousand-man power, it takes its rank
With presses that smite the world in flank,
With type-shed thoughts in splendid line
That march abreast to music divine
For day that never comes night!

A century after Christ was born,
The brooks ran idle as the wind,
And women ground creation's corn
For the molars of mankind;
Five thousand years no wheel for a mill
E'er foamed a flume or ruffled a rill,
But women ground and they pined
Till lordly men had all dined!

This world declared for a cycle or two
The best of things were the old,
Did as its grandfathers used to do—
About as Adam was told!
And thought those sewing machines the best,
[And so would I were I to be pressed,]
In clouded hose and calico dressed
And hearts far richer than gold.

So husbands wore out a couple of lives
That stitched their shrouds as they wrought,
Ordered a slab for each of their wives,
And two willows to weep they bought,
And wondered what the "providence" meant,
That seamstresses and grew weary and went
And set their comfort at naught.

They threshed a few oats with a flail
To club grief out of their heart,
Pulled down the sweep to get at the pall,
Its hoops all ready to start,
Tugged at a ton for the sake of a pound,
Wished for a well on top of the ground,
And locked the barn with a rail.

Ah, had they married a "Singer" or "Howe,"
"Remington," "Grover and Baker,"
"Wilson," "Wheeler," "Domestic," they now,
Should the creak for not suit them to sew,
Might buy direct from the maker
An attachment without any heart,
That if broke could be mended by art,
That would sing to the needle's go-come,
Hum, ever hum! "There's no place like" hum,
No widower's sorrowful brow!

Ah, had they married a sewing machine
And given some woman the doubt,
Not a man of them all would have been
Two graves and two monuments out!

They plow to-day with a wooden crook
Where Orient empires rule,
They drive a team with a Jersey look,
A mother-in-law and a mule!

They sickle the grain about their knees,
They fan the chaff with a Northern breeze
And scorn the use of a tool.
The ugly crook yet elbows the earth
As bad boys nudge at school,
We find at last what teaching is worth
With nothing to learn but a fool.

Where they shingle sheds with old pea straw
And it rains between the showers,
We sent a plow, according to law
Curved like the statutes of powers.
"Here is a god," the savages said,
They set it on end and painted it red,
And crowned it with garlanded flowers.

The Responsibility of Americans.

This lovely and this glorious liberty, these benign institutions, the dear purchase of our fathers, are ours; ours to enjoy, ours to preserve, ours to transmit. Generations past and

The Fourth of July.

We enter this year upon the second century of the Fourth of July. Thus the years are carrying us farther and farther away from the old heroic time when brave men unflinchingly placed their names to a document which would have cost them their lives had the oppressors triumphed, but which, as the right prevailed, gave them undying honor. We would not lose sight of these early, noble deeds. We would not forget that the Fourth of July is not a mere opportunity for fun and fireworks, but that the prototype of the day we celebrate was indeed the birthday of the nation.

To aid the thought in the recollection of the incidents of the brave Declaration, we give an engraving of the exterior and interior of the historic building which has been often called the "Cradle of Liberty." It is old Independence hall, in Philadelphia, of which and the

INDEPENDENCE HALL, PHILADELPHIA.

generations to come hold us responsible for this sacred trust. Our fathers admonish us with their anxious paternal voices; posterity calls out to us from the bosom of the future; the world turns hither its solicitous eyes—all conjure us to act wisely and faithfully in the relation which we sustain. We can never, indeed, pay the debt which is upon us; but by virtue, by morality, by religion, by the cultivation of every good principle and every good habit, we may hope to enjoy the blessing through our day, and to leave it unimpaired to our children. Let us feel deeply how much of what we are and of what we possess we owe to this liberty and these institutions of government. Nature has, indeed, given us a soil which yields bounteously to the hands of industry; the mighty and faithful ocean is before us, and the skies over our heads shed health and vigor. But what are lands and skies and seas to civilized man without society, without morals, without religious culture; and how can these be enjoyed in all their extent and all their excellence but under the protection of wise institutions and a free government? There is not one of us who does not at this moment and at every moment, experience in his own condition and in the condition of those most near and dear to him, the influence and benefit of this liberty and these institutions. Let us then acknowledge the blessing; let us feel it deeply and powerfully; let us cherish a strong affection for it, and resolve to maintain and perpetuate it.—Daniel Webster.

deeds done therein the poet Taylor has written these stirring lines:

A century ago this royal Duke of Years,
A hush fell down on Independence hall,
No rounded phrase, no ringing roll of cheers,
No clash of voices and no sound of feet,
But whilst as spiders on a cob-webbed wall
Festooned with fabrics from their filmy loom,
But whilst as steals a mignonette perfume,
But whilst as surges when two shadows meet,
The brown fly's drone that boomed around the room
Like dream of drummer in a distant street,
The rasping of a pen—and these were all
But waiting breaths on any ear to fall.
That pen was dipped in honor, not in ink,
The men that used it stood on glory's brink.
Name after name went down upon the roll
And lent at last the declaration soul!
Each signed the deed and passed the pen along,
That bound for good and all three millions strong!
That letter stands, I care not what you bring,
Of all mere human words my Lord the King!

Within two thousand years one other thing
Alone has roused the drowsy world and wrought
A revolution grand in human thought,
Endowed the truth with most puissant wing
And Right with Might; the Sermon on the Mount,
The Declaration scroll—the twin complete the count!

A painting hung behind the Speaker's chair
But not more silent than the signers there.
Then Franklin rose, that grand old king of types,
Of fame enduring as the Stars and Stripes,
And said: "I knew not what the artist meant,
A morning sunrise or an evening set,
I could not tell which way the shadows went—
The deed we do this day has strangely let
A light upon the scene no painter lent,
See where the beams of morning westward run!
The sun is ours! It is the rising sun!"

Independence hall is preserved with jealous

care, so that coming generations may share with us the inspiration of entering its portals and recalling the old scenes. Interest centers on the building and its contents, and in connection with the engraving we give the following description from the pen of a recent visitor: The east hall has a goodly number of historic relics, most worthy of note among which is the famous old Liberty bell, which rang out melodies for the sons and daughters of the new land a hundred years ago, but now shows the fingers of time in a huge fissure. Here is the old front door belonging to the Chew mansion, which was battered and splintered at the siege of Germantown. Dresses of "ye olden time" are abundant, showing that loving descendants of the men and women of those days have guarded them carefully. A piece of one of "Lady Washington's" dresses is a flowered cambric—quite like the gay chintz so much in vogue for lounge coverings now. Here are portraits of all the signers of the Declaration, officers of the Continental army and members of the first Congress. The Georges are there, too. Is it prejudice, or do their faces look out from the canvas crafty, sensual and selfish? Jars and chairs and tables used by Gen. Washington, have a charm about them from the thought that they have been part and parcel of his plain household—a thought which redeems their excessive homeliness.

The original Declaration of Independence, with paper brown with age, ink faded and dim, has a mysterious awe about its immortal wording. Close by is the veritable inkstand into which those grand men dipped their quills, one after the other, as they traced those names which the tongue of history shall ever be proud to repeat. The inkstand is heavy and cumbersome, is made of solid silver, and bears the maker's name—Philip Syng, 1752. The first draft of the Constitution hangs in a frame, a conspicuous object of attention.

There are several portraits of Washington, taken at different ages. William Penn is here, in company with his second wife—a wholesome, plain, sensible sort of a lady. The face of Francis Key, the author of the Star Spangled Banner, is sparkling and refined. Marquis de Lafayette, the noble Frenchman, is gentle, courteous and soldierly. In this hall, in a case, are numerous articles of the toilet—dresses, stomachers, towels, stockings, high-heeled slippers, laces, over-dresses, ribbons, etc., all of great antiquity; also table articles, such as spoons, knives and forks, sugar bowls and similar things.

Here is the celebrated painting by Benjamin West, depicting Penn's treaty with the Indians. The subject is true to life. In the shade of the lofty woods, the Indians and whites have gathered to listen to their "pale brother," as he stands there, earnestly setting forth the conditions of the treaty. The old chiefs are gravely listening, while their eyes are turned calmly upon him, as he stands there, surrounded by his friends. The women of the tribe have drawn near to hear the "big talk," while the half-naked boys and girls, with their symmetrical limbs, are amusing themselves near. The figures are clear, bold and natural. Here, too, are many original letters of Benjamin Franklin, written in the troublous days of our country, when his heart was full of forebodings lest her leaders went not right. How his great soul would be troubled could he have a chance to observe them now! With a long look at the many treasures this room contains, I cross the hall to a room filled with old portraits of the prominent men of those days; look at some old, stiff and uninviting chairs and settees, and ascend to the two halls above, in which the present city council hold their sessions. Both these rooms are fitted up in modern style, with rows of desks and a few easy chairs. It was for, merely one room, known as the banqueting hall—where, on all state occasions, the festivals were held. Here Washington delivered his farewell address to the Continental Congress, whose deliberations took place in this hall. There is a splendid painting representing him in the act of making this last speech, which hangs over the very spot where he stood. The city of Philadelphia paid \$30,000 for it, and they claim that it is the most accurate likeness of him in existence.

Our Country's Origin.

Our fathers came hither from a land to which they were never to return. Hither they had brought, and here they were to fix their hopes, their attachments and their objects. Some natural tears they shed as they left the pleasant abodes of their fathers, and some emotions they suppressed when the white cliffs of their native country grew dim in their sight.

A new existence awaited them here; and when they saw these shores, rough, cold, barbarous and barren, as they then were, they beheld their country. Before they reached the shore they had established the elements of a social system, and at a much earlier period had settled their forms of religious worship. At the moment of their landing, therefore, they possessed institutions of government and institutions of religion. The morning that beamed on the first night of their repose, saw the pilgrims already established in their country. There were political institutions, and civil liberty, and religious worship. Poetry has fancied nothing in the wanderings of heroes so distinct and characteristic. Here was man, indeed, unprotected

and unprovided for on the shore of a rude and fearful wilderness; but it was politic, intelligent and educated man. Everything was civilized but the physical world. Institutions containing in substance all that ages had done for human government were established in a forest. Cultivated mind was to act on uncultivated nature; and, more than all, a government and a country were to commence with the first foundations laid under the divine light of the Christian religion. Happy auspices of a happy future! Who would wish that his country's existence had otherwise begun? Who would desire the power of going back to the ages of fable? Who would wish for other emblazoning of his country's heraldry, or other ornaments of her genealogy, than to be able to say that her first existence was with intelligence; her first breath the inspirations of liberty; her first principle the truth of divine religion.

The Disinterestedness of Washington.

To the pen of the historian must be resigned the more arduous and elaborate tribute of justice to those efforts of heroic and political virtue, which conducted the American people to peace and liberty. The vanquished foe retired from our shores, and left to the controlling genius who repelled them the gratitude of his own country, and the admiration of the world. The time had now arrived which was to apply the touchstone to his integrity—which was to assay the affinity of his principles to the standard of immutable right. On the one hand, a realm, to which he was endeared by his services, almost invited him to empire; on the other, the liberty to whose protection his life had been devoted, was the ornament and boon of human nature. Washington could not depart from his own great self. His country was free—he was no longer a general. Sublime spectacle! more elevating to the pride of virtue than the sovereignty of the globe united to the scepter of ages! Enthroned in the hearts of his countrymen, the gorgeous pageantry of prerogative was unworthy the majesty of his dominion. That effulgence of military character which in ancient states has blasted the rights of the people whose renown it had brightened, was not here permitted, by the hero from whom it emanated, to shine with so destructive a luster. Its beams, though intensely resplendent, did not wither the young blossoms of our independence; and liberty, like the burning bush, flourished unconsumed by the glory which surrounded it.

To the illustrious founder of our republic was it reserved to exhibit the example of a magnanimity that commanded victory—of a moderation that retired from triumph. Unlike the erratic meteors of ambition, whose flaming path sheds a disastrous light on the pages of history, his bright orb, eclipsing the luminaries among which it rolled, never portended "fearful change" to religion, nor from its "golden tresses" shook pestilence on empire. What to other heroes has been glory would to him have been disgrace. To his intrepidity it would have added no honorary trophy to have waded, like the conqueror of Peru, through the blood of credulous millions, to plant the standard of triumph at the burning mouth of a volcano. To his fame it would have erected no auxiliary monument, to have invaded, like the ravager of Egypt, an innocent though barbarous nation, to inscribe his name on the pillar of Pompey.—*Robert Treat Paine.*

The Freedom of Science in America.

The quick and keen sense of self interest that gives such sagacity and energy to the business operations of this country, is equally propitious to the success of every art, every discovery, invention, undertaking and science, that involves in it any amount of practical improvement or power. Hence whatever of theoretical science, inventive skill, ingenious speculation or reasoning eloquence can be made to tell upon any of the multitudinous affairs making up the business of life, or to minister in any way to the increased power and enjoyment of man, will soon find ready attention for their claims. Here no prejudices in favor of time-honored usages are strong enough long to resist the advance of scientific improvement or wise innovation. Society is not divided into castes, each one of them watching with jealous vigilance against any encroachment of their several exclusive walks by any rude intruder from another class, themselves clinging to the settled usages and old forms of their own clan, with the steady pertinacity of men whose unexamined prejudices are interwoven with their earliest habits and their most valuable personal interest. If science, descending from her starry shrine in the heavens, light the student to any discovery or invention in any manner applicable to the wants of his fellow creatures, if genius prompt the lofty thought, if love of God or of man inspire the generous design, no matter how the novelty may astonish for the moment, no matter what prejudices may be shocked, no matter what interests may be alarmed and band themselves against the innovator, let him go on undismayed; he advances to certain victory.

Silver Mud.

Our readers will remember that not long since there was some little excitement in Oregon over certain mud springs said to contain silver in large amounts. Some of the "silver" mud was sent to Professor Silliman, who made an analysis of it and pronounced the whole thing a fraud, stating that it had evidently been prepared with intent to deceive. Companies were formed and some of the stock sold in Oregon. After we published Professor Silliman's letter we heard nothing of the subject until at a recent meeting of the State Geological Society, Mr. H. G. Hanks read a paper on the subject, in which he takes the ground that the production is evidently natural and not "salted." As Professor Silliman in his letter gave his reasons for thinking that the mud was doctored, we give Mr. Hanks's paper, which states his reasons for thinking to the contrary. It will be interesting to see the result of the analysis of the silver-bearing substance from Utah described by Mr. Hanks. He says:

It will be remembered that some months ago specimens were sent to this city from Oregon, purporting to be mud from certain springs newly discovered, and which were found to be rich in silver, as claimed by the parties who sent them. The occurrence of springs yielding soft mud, highly charged with free silver, is, as far as I know, new to science. Under the circumstances, such a statement could hardly fail to be doubted. Some of this singular substance was examined by gentlemen of high scientific attainments, both in this city and in the East, and was pronounced without hesitation fictitious. Specimens naturally found their way to the Microscopical Society, and were referred to me with a request that I would report on them.

My examination revealed certain features which I could not reconcile with the theory of their having been purposely prepared to deceive the public. At the same time I could not evade the suspicion that such was the case. I found the substance very rich, and on microscopic examination discovered that the silver was in a free state. By simple washing the silver could be wholly separated, and when then examined the microscope failed to reveal the source of the precious metal. Had it been filings, a single glance would have sufficed to detect that fact. Had the silver been precipitated from solution by copper, it would have been crystallized. An amalgam of silver and mercury would have yielded a sublimate if strongly heated in a glass tube closed at one end. Such an amalgam introduced into the wet mud, and the whole heated sufficiently to volatilize the mercury, would have left the substance in a hard baked state, which could not again have been reduced to the state in which it reached this city. From these conclusions I was led to state in my report to the Microscopical Society that "if the silver had been introduced for fraudulent purposes, which I could scarcely doubt, the substance was still remarkable, as the person who produced it had so skillfully covered his tracks that I could not with certainty declare it a fraud."

Subsequent examinations of other samples confirmed my doubts as to its being an artificial production. Some time after I met a gentleman, well-known in San Francisco, who has for some time resided in Oregon, who had seen many samples of "silver mud," and who firmly believed it was a natural production. In conversation, I asked him to refer me to some perfectly reliable person with whom I could correspond on the subject. He gave me the name of Richard Hurley, with the assurance that I might place implicit confidence in any statement he might make. I then addressed a letter to Mr. Hurley, asking for information. I stated in my letter that his friends here had the utmost confidence in his integrity, and that they had desired me to address him. I also asked him to send only such facts as he had learned by personal observation. The following letter in answer to mine came in due time:

"DEAR SIR:—Your letter of March 19th is received, and it will be a pleasure to me to give you all the information I can in regard to this camp. "There is no mistake as to this mud containing silver. I have been here over two months, and have assayed over 100 samples which contained silver; some as high as \$2,300 to the ton. The samples I obtained from the springs myself. I think the weather has considerable to do with the mud containing silver. I obtained the best results when the weather is warm. Sometimes in one of the larger springs when the weather is cold the mud will be of a yellow color, showing no silver, but when the day is warm the mud is blackish-blue, at least in places, and rich in silver. They seem to work more actively in a warm afternoon. Some of them contain a great deal of acid, the bones of animals that fall into them being dissolved in a few moments.

"There are old wells that assay from \$5 to \$1,200 to the ton. One assay I made from the flat, half a mile from any spring, assayed \$1,200 to the ton. There is a great deal of salt, almost pure, all over the spring flat. There are between 100 and 200 quartz leads discovered, running in two directions close to the springs. I find silver in several of them, all the way from a few dollars to \$100 to the ton. Some of

these leads run through the springs, at least they point in that direction. The altitude of this place, I should judge, is between 4,000 and 5,000 feet. I have no means of ascertaining at present the exact height.

"I will send you some of this so-called mud as soon as it stops storming. I want to take some out when the weather is warmer.

"RICHARD HURLEY.
"Silver Springs, Wasco Co., Ogn., April 19th, 1877."

In this connection I would state another interesting fact which has come to my notice. A recent discovery of a silver-bearing deposit, located in southwestern Utah, has been made public, and specimens of this interesting substance have reached this city. It occurs in the Maud mine, Toquerville, six miles from Leeds. The deposit is said to be sandstone. Some assays, as high as \$700 per ton, have been made. Some specimens have lately come into my possession and I have examined them with care. Instead of being sandstone, I found the deposit to be sedimentary, but closely resembles the Oregon mud. Under the microscope it has all the appearance of that strange substance and does not, in any way, resemble sandstone. It scratches glass with difficulty; some samples slip over the surface of a glass plate without making any impression on it. The Oregon mud, if allowed to dry in large quantities, would soon form a substance similar to the Utah mineral, in appearance at least. The silver is in the state of a chloride, and easily seen under the microscope, both amorphous and in crystals. An analysis of the two minerals will be interesting, and may throw some new light on the subject. It is possible that a study of these deposits may contribute much to our knowledge of the formation of metalliferous veins.

Arizona Mines.

Since the establishment of our Territory, 14 years ago, our mines of gold, silver, copper, iron, etc., never have shown such signs of richness and permanency as at the present time.

Pima county has a great many very valuable mines that are being sought after by English capitalists, as well as those from California and other States. The King, in Pinal, is turning out probably the richest ore of any of our many wondrous deposits, and is attracting much attention from mining men and capitalists on the outside.

Here in Yavapai, our home, where we know what we are talking about, there are hundreds of mines that pay into the thousands per ton, and are only too ready to yield up their shining wealth to the honest miner, the echo of whose hammer reverberates from every hill and dell throughout our mountains, which are bound together with threads of gold and silver. The Peck, Zalida, Black Warrior and such mines are enough to convince the most skeptical that the mountains surrounding our home, Prescott, situated in the midst of a beautiful forest of pine, juniper and oak, are one vast table of metallic wealth. Such wealth and treasure as those that surround us on every side and in every section of our fast-growing Territory are gifts that are only bestowed upon the pioneer, who severs himself from all that is dear and near to him, gives up comforts to partake of hardships, leaves peace and quiet to brave the dangers, penitence for insufficiency, etc. Such has been the case with the pioneers of Arizona, and now they are beginning to realize that a brighter day is about to dawn upon and crown their noble undertakings.—*Arizona Miner.*

THE GEOGRAPHICAL SURVEY.—Major Powell, U. S. A., in charge of the geological and geographical survey of the Territories, has already sent out five parties, all of which are at work in Utah Territory. The triangulation party, under Professor Thompson, is located on the eastern slope of the Wahsatch mountains. Three geographical parties, under Messrs. Renshaw, Wheeler and Grover, are pretty busy prosecuting their work on the Uintah, Price and Lower Green rivers, and a geographical party under Captain Dutton, of the Ordnance Department, U. S. A., is located on the central plateau. Major Powell will leave here about the 1st of July for the field, and in the meantime two other parties will be fitted out for work this season, one of which will make a specialty of the subject of irrigation in Utah. It is expected that the geographical work in eastern Utah, which has been prosecuted with vigor for some years past, will be finished this season. The survey now being made of the Pacific coast by the United States Engineer Corps, comprises all the country lying between the British possessions on the north, the boundary line of Mexico on the south, the Pacific ocean on the west, and the meridian of 100 degrees on the east. The work so far completed includes the survey of about two-thirds of Arizona, nearly the whole of Nevada, and a portion of New Mexico and Colorado. The extension of the Southern Pacific railroad to Yuma has offered such additional facilities to the survey party that the survey of Arizona will be rapidly carried on and soon completed. A number of topographical atlas maps have been prepared, embracing each an area of 80 square miles, showing the drainage basins of the different sections and the several elevations of the various mountains.

Mica and its Uses.

Mica, from the Latin "to shine," is composed of silice, alumine and potash. It is found in almost every country on the globe—America, Switzerland, Siberia, Norway, Bohemia and Russia. Siberia and the United States probably furnish the best and largest specimens. It occurs in granite and quartz, also in rubellite, green tourmaline, feldspar, lepidolite and several other minerals. It is one of the constituents of granite, gneiss and mica schist, talc-slate, etc. It sometimes occurs in granular limestone, and rarely in lava, dolomite and magnetic iron ores.

According to Dana, mica is usually in thinly foliated plates or scales; color from white through green, yellowish and brownish shades to black with a pearly luster, transparent or translucent; before the blowpipe infusible, but becomes opaque white.

There are a number of varieties. That in which the scales are arranged in plumose form is called plumose mica; that in which the leaves or scales have a transverse cleavage is called prismatic mica. The crystals are chiefly rhombic or six-sided, though not always.

The cleavage of mica is highly perfect, and, according to Prof. Henry, can be split or divided into leaves, 250,000 to the inch. It shows a tendency to associate with quartz, and in the mines recently discovered in New Mexico a coarse quartz mixed with fine white crystal formation is the sign of the mica mine. Many deposits or veins have been discovered by myself and Mr. Phillips during the winter, but a very small per cent. carry mica of a merchantable quality; the cleavage is generally transverse, or foreign coloring matter enters it to such an extent that it is worthless for market.

The uses of mica are various. Diamond dust with which court dames, and our own American ladies, powder their hair, is ground mica. The costly French silver moldings are cast from ground mica. The wonderful shower of diamonds which I have witnessed in the scenic plays of the White Fawn and Black Crook, at Niblo's, was mica scales.

As a lubricant it is perfection. Mixed with oil it wears longer than any other ingredient. Recent experiments have proven that in any swift-running machinery, where the Babbitt metal and other packing have proven at fault, mica packing is perfect; being indestructible by heat it generates none, and as soon as a good Yankee test is made, the result will be mica-packed boxes for fast, heavy-running machinery, and no more hot boxes or worn journals, being entirely free from grit.

For stoves it has now become indispensable, and the demand for clear, transparent mica is rapidly increasing.

We have opened five mines during the past three months, and out of over 40 veins, which I have examined since last November, these five are the best. The quantity which these mines can produce is unlimited, and the quality equal to any in the United States. I have carefully compared it with mica from the mines of North Carolina, of S. Royalston, N. H., and of Paris, Maine, where mines are now being worked; from what I can learn of mines in other parts of the United States, and over the water, I am led to believe that we have a much larger deposit and of larger sizes than is now found in this or any other country.

Large plates, when they could be procured, were at one time used in the Russian naval vessels for deck or dead lights, because not liable to fracture from concussion. It is in common use for lanterns, and is rapidly coming into use for lamp chimneys. On account of its transparency and toughness, and the thinness of its folia, it has been used as glass in Siberia, but is now too costly for common use.

It is not difficult to find mica in the district in which our mines are located, but after many months spent in prospecting, exploring and working, I find that to find the perfectly clear, transparent, flexible mica, free from color, veins, curves and other imperfections, is very difficult. Sizes as large as 14 inches have been found in North Carolina. We have not unfrequently sized from 18 to 24 inches. Last week we took out one book or crystal weighing fully 100 pounds. We are now able to furnish mica by the ton. Crude mica, i. e., pieces too small for cutting, and the cuttings, are too far from market and the uses of waste mica too limited to render them valuable. Sizes less than two and one-half by four or four and one-half inches are hardly worth saving. Sizes five by seven and nine inches are worth \$6.50 to \$7.40 per pound, with a rapid increase in prices for larger sizes.

I made an extended tour of observation through New Mexico with Gov. Hunt and Col. C. B. Lamborn, of the D. & R. G. railway, a few weeks ago, and returned to our mines fully satisfied that the small district in which we are now operating contains about all there is worth looking for in that line in that Territory.

Some deposits or veins are often found at a distance from us, but after a thorough investigation and an expenditure of labor and money, have been abandoned, the quality not proving satisfactory. The mica which I have so far exhibited from our mines has all been taken from within one to three feet from the surface.—*Cor. San Juan Prospector.*

THE war is already benefiting American shipmasters, as for long voyages merchants prefer chartering flags not likely to become embroiled in the present war.

The Week.

The week just passed has been an uneventful one, as far as the mining interests are concerned. Stocks have not "boomed" to any extent, and nothing startling is reported from the mining districts. On the Comstock, several mines which lately shut down, have started up again, a result brought about by the late rise in stocks. We notice also that work is to be commenced in Panamint district on some of the big mines which have been idle for some time. This district, which created a great excitement at the time of its discovery, has long been under a cloud, but many pin their faith to it yet and are anxious to see "depth" on some of the shafts. Another event of interest to a certain class of the mining community is the appearance of Mr. Goodyear's book on the "Coal Mines of the Pacific Coast," noticed in another column. This is a very important and valuable treatise, and one long needed. We hope now that some competent person will also undertake the task of writing a work on the quicksilver interest of the State. It seems strange that this has not been done before, as these interests are larger here than anywhere in the world. The deposits are largely scattered over the State, and many inquiries are made for some work which will describe the nature of the deposits, give instructions as to prospecting and mining as well as metallurgical operations. Will not some competent practical mining engineer take this matter into consideration? We are sure a small book on this subject would be ready of sale, to a certain extent.

THE Virginia Enterprise says: "Some young men, miners out of employment, on a visit to Washoe lake, and in search of something out of which to coin funds for the Fourth of July, found in the hills east of Washoe lake recently sledge, the croppings of which assay \$42, staked their notices, and are happy."

Close of the Volume.

With this issue we close Volume XXXIV. of the MINING AND SCIENTIFIC PRESS. A glance at the capacious and comprehensive index on the last page will show what a variety of subjects have come under our observation during the past six months, and will, at the same time, be a guarantee to new subscribers that the PRESS omits mention of nothing which will be likely to be of important interest to progressive readers.

This index is a matter of considerable labor to compile, but it is of great value to those who file their papers, forming an encyclopedia which gives a complete record of industrial progress or the period covered by the volume. In a file of this kind will be found facts gained from every-day work, and hints from practical men in all industrial departments. It forms a very complete history of mining operations on this coast, so that those interested in this industry can refer at any time to what was the condition of any particular mine at any stated period.

The MINING AND SCIENTIFIC PRESS is now about to enter on the eighteenth year of its existence—a long period in a comparatively new country like this. During all this time it has been devoted to the interests of the industrial classes of the Pacific coast, and has endeavored in every way to be of benefit to them. The paper has been improved from time to time as occasion offered, and the proprietors are encouraged to believe that these improvements have been duly appreciated. We shall endeavor to continue to make the PRESS in every way worthy of the interest it represents and to add to its value at every opportunity.

To the mining community all over the coast the PRESS is of the greatest value. No one at all interested in mining matters can afford to be without it. The current mining news of the day alone, which is compiled with care from all reliable sources, is worth more than the subscription price. The "Mining Summary" which appears each week gives a birdseye view of the state of affairs in the different mining centers of the coast and any one interested in any particular camp can see what is going on there, as well as gathering a general idea of the prospects of other localities.

Our numerous correspondents, writing intelligently from various places, give details of operations in their respective localities which are widely read. Our special traveling correspondents, who write up the various camps all over the coast, manage to gather a mass of information which is not available from any other source. The letters which have appeared in this volume from Montana, Utah, Nevada and different parts of California from one of our traveling correspondents alone, have gone over a great deal of ground and conveyed a great deal of practical information gathered in different places. Many of these communications have been copied into Eastern and foreign journals, thus carrying abroad information of our rich resources.

We have, as usual, carefully watched for all the improvements in mining appliances which have come in vogue, either in this country or in Europe, and described them in detail for the benefit of our home readers. All the new inventions in this line have also been described, as have such new processes for the reduction of ores as have been practically applied.

In short, the MINING AND SCIENTIFIC PRESS forms a compendium of useful and practical knowledge and applied science superior to any other journal for the requirements of the classes it represents on this coast. Legitimate mining, no matter on how small a scale, it is its province to encourage; and, not being in the slightest degree bound to any set or clique, we are in a position to do justice to all legitimate undertakings, and, when necessary, condemn those which savor of fraud. The paper has now been so long established and its proprietors have had so much experience as publishers, that it is on a firm basis and in a position to be perfectly independent. Our advertisers, who, in a measure, co-operate with subscribers in sustaining a first-class paper, are among the best class of people in their respective lines of business, and the continuous time which a large proportion of their advertisements have appeared in the PRESS shows the appreciation in which the paper is held and proves that the investment is profitable to them.

The PRESS circulates in every mining camp on the Pacific coast, as well as largely in the cities, and those who take it once are apt to continue to do so. There are of course many who may not have had an opportunity to judge of its merits, but who would be likely to subscribe should our old subscribers who are familiar with the PRESS call their attention to it.

Miners and mechanics should support their home paper properly, and not only subscribe for and read it, but also write for it occasionally. To publish a paper of the style of the PRESS is an expensive undertaking, and it is but just to expect the hearty support of those to whose interests it is devoted. The commencement of the volume is a good time to subscribe, and we hope that our readers will assist us in drawing the attention of other persons engaged in industrial pursuits to the merits of the PRESS and induce them to subscribe. The publishers are determined to have the PRESS continue to occupy the leading position among Pacific coast mining and industrial journals, and will spare no labor or expense in furtherance of the object.

The Pioneer Press of Nevada Co.

We are requested by several old residents of Nevada county to publish the following remarks of W. B. Ewer in reply to "The Pioneer Press of Nevada County," a sentiment given at the Nevada County Reunion, held in Badger's park, Oakland, June 9th, 1877:

I feel all the more honored, Mr. President, in being called upon to speak to "the pioneer press of Nevada county," from the fact that it is well known I am no speech-maker. I have been called up simply because of the accident of my connection with the "pioneer press" and because I happen to know something about it. If there is any one thing in connection with my early California life in which I take an honest pride, it is because of my connection with the pioneer press of Nevada county.

The Nevada Journal, the first newspaper published in Nevada county, was the second established in the mountains of California. Perhaps a few words in connection with the circumstances which called it into existence, and some of the incidents connected with its early history, may be interesting at this time:

There are, no doubt, many here who well recollect the first great fire in Nevada City, which occurred on the morning of the 11th of March, 1851, and which was the first of the many great fires which, during her early years, wrought such destruction throughout the cities and principal mining towns of California.

At that time I was employed as foreman on the Placer Times, then published at Sacramento by Messrs. Pickering & Lawrence. The second morning after the fire I was called into the editorial room by Mr. Pickering and introduced to Mr. J. N. Turner—every old Nevadan will remember Nick Turner. Mr. Turner had just arrived at Sacramento, and called at the Times office to give the particulars of a great fire at Nevada City, a place with which we had already, at that early day, become quite well acquainted. After Mr. Turner had concluded his story I remarked to Mr. Pickering that it would be quite California-like for some one to rush up to Nevada and start a paper there directly upon the heels of such a calamity. The excitement of the occasion, and the bustle of rebuilding the city would act as a stimulus to the enterprise. Mr. Turner became at once very much interested in the idea, and Mr. Pickering suggested that, as I had proposed it, I should proceed at once, and without delay, to carry it out.

As a result of this interview a "solitary horseman" might have been seen the next morning, wending his way across the Sacramento valley towards Nevada, via "Johnson's ranch," that and on foot being the only modes of travel in those days toward the mountains. I arrived in Nevada while the ruins of the fire were still smoldering, presented my letters of introduction from Mr. Turner, was cordially received, and so liberally encouraged that I hastily returned to Sacramento, purchased press and types, and on the 21st day of April, 1851, issued the first number of the Nevada Journal, as a semi-weekly paper.

Some three months after the Journal had been started, a young man—a miner—came into my office from one of the neighboring ravines, and introduced himself as a printer—would be willing to do a little work at the "case," or assist in editorial labor. He soon after handed me several pages of manuscript, from the perusal of which I readily perceived that he was well qualified for editorial labor, and that he would some day act no inferior part in the political management of his adopted State. A few weeks later I met him in a caucus called for the purpose of effecting a county political organization of the party to which he was attached. This meeting, I believe, was the first attempt in the mountains of California to turn the attention of men from the all-prevailing hunt for gold, to the benevolent purpose of teaching them how to vote.

I need hardly say that the then young printer and "honest miner" is now before you and represents the State of California in the National Senate—fully the peer of any of his distinguished colleagues. I suppose Mr. Sargent would hardly care at this time to take a "case" in my printing office; although I have no doubt he could set a column of type fully as quick and quite as correctly as the general average of printers.

In the fall of 1851, having been seized with a very severe attack of "quartz fever," a condition which was so prevalent at that time, and so fatal to life and hope and pocket, I sold out my interest in the Journal to Mr. W. G. Alban, who soon after associated with himself Mr. Sargent, as editor. Mr. Sargent continued to furnish the leading editorials for the paper for some four years, until July, 1855, when he was succeeded by Hon. E. G. Waite. Mr. Waite continued in charge of the paper until its suspension in 1861. I think it will be acknowledged by all who knew the paper that no journal in the mountains of California had a wider influence, during its ten years of existence, than had the Nevada Journal—after I left it.

After a suspension of something over a year the Journal was resuscitated by Rev. Benj. Brierly, and continued for about a year and a half, when the pioneer paper of Nevada county

finally and fully gave up the ghost in the sea of fire which for the third time swept over the city of Nevada in November, 1863.

The press and a portion of the type of the Journal office possessed no little historical interest, and it is much to be regretted that the material could not have been spared by the devouring element to occupy a place which it eminently deserved to fill among the most interesting pioneer relics of California.

From the best information I can obtain, the press on which the Journal was printed was the identical one used by Walter Colton and Robert Semple in the publication of the Californian, which was established by them at Monterey, August 15th, 1846, and was the first paper printed in California—a quarto form of two columns to the page.

Mr. Samuel Brannan started the Star in San Francisco, January 9th, 1847—just six months later. The two were united as the Alta-Californian, on the 3d of January, 1849. My information and belief is that the pioneer press—the one used by Messrs. Colton & Semple at Monterey—was taken to Sacramento in the summer of 1850, by the "settlers"—squatters they were then called—of that city, and used in the publication of their short-lived organ—the Tribune. It was subsequently purchased by Pickering & Lawrence, for the Daily Index, an evening political paper, and by them sold to me as the press outfit of the Nevada Journal. If I am correct in these particulars, the pioneer paper of Nevada county was printed during its entire existence on the pioneer press of California. That press was destroyed by fire, as already stated, in 1863.

The Brannan press was taken to Sacramento by Mr. Lawrence, and used for a while in the Placer Times office, and subsequently taken to Sonora, where it was soon after destroyed by a mob.

But whatever may have been the facts in regard to the press, it is quite certain that a large portion of the type first used in printing the Nevada Journal was the identical type on which the pioneer paper of California was printed at Monterey. There was also a wooden composing-stick in the Journal office which was taken from a few printing materials constituting a primitive job office used by the Spanish mission at Monterey, and probably made by one of the mission fathers, as it was evidently not the work of mechanics accustomed to such manufacture. Probably the first printing ever done on the Pacific coast was done at that office.

A similarly primitive office found its way, as early as 1843, to a Protestant missionary station among the Nez Percés Indians, in the Walla Walla valley, near where Walla Walla City now stands, in the southeastern portion of Washington Territory. Portions of the Scripture were printed at that office in the native Indian tongue.

The first paper ever issued on the Pacific coast was the Oregon Spectator, which made its first appearance at Oregon City in February 1846—some six months earlier than the Monterey paper already alluded to.

Printing materials were very scarce on this coast, both before and for some time after the advent of the gold-seekers, and printers were often compelled to resort to various substitutes for lack of better material. The first printing done at the mission station in the Walla Walla valley, already alluded to, was done on a press made by the man—not a printer—who owned the office. I have been told that this press is still in existence. Mr. Brannan's material came out with not a single composing stick, and a couple of wooden ones were manufactured to supply the deficiency. While in the Placer Times office I ran short of leads, and manufactured a lot from tin, which soon rusted so badly that I could not use them. I subsequently made some from a sheet of zinc, which answered a very good purpose. Some of those zinc and tin leads were taken to Nevada. I also made several fonts and parts of fonts of wooden job type, which I used both at Sacramento and Nevada.

Soon after starting the Journal, I found it impossible to get any printer's ink in the State. So to keep the office running I got a lot of lamp-black and boiled oil and improvised a printer's ink factory. It didn't succeed very well, and I quit the business. But I made ink, and printed several numbers of the Journal with it, and used it for several weeks in all of my job work. Yellow and brown wrapping paper were also used for several issues of the Journal, when white could not be obtained.

The second paper started in Nevada county was the Young America, which made its first appearance in September, 1853. Many here present will recollect the circumstances under which that journal came into existence. It fell to my lot, in connection with Mr. T. H. Rolfe, now deceased, to act as its printer, but not publisher or editor. The new paper, under the editorial management of R. A. Davidge, became at once a very active opponent of the Journal. It soon changed its name and proprietors, however, and became the Nevada Democrat, a name retained, under various changes of ownership and editors, until its decease in the spring of 1863.

The publication of newspapers in Nevada City at that time was occasionally attended with some little unpleasantness. Our honorable Senator, here present, has no doubt some recollection of this fact, and probably will remember the old oak tree, which for many years formed quite a prominent object in the middle of Broad street. He didn't go up that

tree, however; neither did he dodge behind it.

I have myself a very distinct recollection of another affair, in which the Senator bore no part, but in which two gentlemen who could not quite think alike, and when other argument failed, resolved to settle their differences by an appeal to the pistol, but outside of the "code," however. They each emptied a six-shooter, with no worse result than a ball buried in a calf of a leg of each. The second shot from one of the parties entered the *Young American* office directly in front of the "stand" at which I was at work, and spent itself in perforating a half-inch piece of hard wood, which formed a portion of an upper case of type in the "rack," but for which intervention I should have received the missile with nearly its full force, centrally, and a little below the belt. I sprang to the door to learn the cause of the shooting, and as quietly as was consistent with circumstances, suggested that the middle of the street was a better range for such practice, that an intervening printing office was quite too much of an obstruction between combatants to make such an affair interesting. One of the combatants had sought the friendly cover of a corner of the building.

In November, 1853, about two weeks after the *Young America* made its appearance in

Printers, as toilers, are quite unlike other industrial classes. Their work and their toil is for the ages. The printer has been, not inaptly, called "the adjutant of thought." Men in a printing office, whether they set type or prepare "copy," are ever behind the scenes. They know how reputations are made and unmade. They know that what appears the golden crown is often but pasteboard. Life to them is stripped of its illusions; it is unidealized, real. The realm of the press is an enchanted one. When we see a printer picking up his little types one by one, and marshaling them side by side in solid rows, we behold the veritable foot-prints of thought, as it steps out with undying impress into the world of intelligence. Those types are the elements of perpetuity. By them we bridge the chasm of ages, over which those who are to come after us, and who may live myriads of years in the distant future, will be able to travel surely back through the mazes of the wonderful years which have witnessed the birth of the steam engine, the railroad, the electric telegraph, the sewing machine and the power printing press.

The newspaper is the institution of the age. It is the great modern repository of useful knowledge. By it the thoughts of men go forth, weaving silently, thread by thread, the

The Pliocene Rivers.

Generally speaking, miners care very little about geology and know very little about it, although the subject is so intimately connected with their every day business. There is one department of the science, however, in which the miners of California take great interest. Those who have ever had anything at all to do with gravel mining are desirous of becoming acquainted with the wonderful geological events which preceded and led immediately to the present configuration of the country embraced within the Pacific States, and during which the immense deposits of auriferous gravel now being worked were formed. Unfortunately the State Geological Survey was stopped before the work was accomplished, and a great deal of the information which was gathered remained unpublished.

Among other things unpublished, but prepared, was the map of the Pliocene rivers of California—something of the greatest interest to gravel miners. This map was all completed several years since, and the State should see that it is published. It will be seen by the letter of our special correspondent from Nevada

The Celebration in the City.

Active preparations are being made by the different committees having the matter in charge, for a successful celebration of the Fourth of July in the city. The feature of the day will be, of course, the procession. The military companies, are, as usual, all ready for the parade and a large number of the societies of the city are also making preparations, having signified their intention to turn out. The procession in San Francisco has always been a success and there is no reason to believe that there will be any exception this year.

The literary exercises will take place at the California theater. Henry George has been chosen as orator of the day; Geo. H. Jessop, poet; and Henry Edwards, reader of the Declaration of Independence.

There will be no exhibition of fireworks in the evening, experience having proven that the winds prevailing at this season of the year are apt to spoil the exhibition and also add to the danger of fire. The Board of Supervisors have before them an order amending the present or-

THE FOURTH OF JULY BY MOONLIGHT.

Nevada, the *Telegraph* was started in Grass Valley, by Messrs. Oliver & Moore. That paper may also be considered as one of the pioneer papers of Nevada county. It came into my hands at the commencement of the second year, and was continued as a weekly until 1861, when its name was changed to the *Grass Valley National*, under which name it ceased to exist in 1870.

And now a few words in regard to the press, and printers in general, and I have done.

Printers, Mr. President, are very modest and unassuming men; they profess but little and claim but little for themselves, but the world freely accords them much. Neither the wealth of knowledge which they garner up from year to year, nor the vast benefits which they confer upon the world, inure much to their own advantage. It usually either lies dormant or is used to the credit and advantage of others. Printers are not aspiring men. Their highest ambition is to benefit others. If, by force of circumstances, they chance to be separated from their profession and brought into public life, their garnered and varied knowledge stands them in good account, whether in the forum, in the lecture room, or in the legislative hall. The education gained in a printing office, though not so thorough and complete as that of the school or college, is far more practical and gives its possessor an advantage which many covet, but which few possess.

great web of human intelligence. Away across the water, over the prairie, up the mountain side and down the river valleys, everywhere go the white-winged messengers of the press to furnish thought for the million, to tell men how to mine, how to sow, how to reap, how to think, and how to vote. To teach them whatever is useful, whatever is good, and to warn them against evil and the evil doer. Princes and potentates own the sway of the press; there is no mightier power in all the world than printer's ink rightly used.

As the printer stands at his case, weary and worn, or sits at his table burning the midnight oil in the preparation of his "copy," though he may not be able to command the meanest servant, and has not an acre on God's footstool to call his own, he nevertheless knows that he is a power in the world. With his fingers he is putting thoughts into shape that will penetrate everywhere; with his "mallet" he is "locking up" "forms" that will make an "impression" on rings and on powers. His "shooting irons" are far more powerful than any which Colt or Remington, or even the great Krupp himself, ever fashioned.

ONE THOUSAND to 1,500 men are now on a strike in the iron manufacturing establishments at Schuykill, Lehigh and Susquehanna valleys, against a reduction in wages. The number will shortly be increased.

county that a private individual is at work on a smaller scale with a map of the same sort, showing the need of such a map as was compiled by the survey. Nothing could be published which would be of greater benefit to California miners than the Pliocene river map, and some of our rich mining men might make an offer to the State to publish it, as the "Botany of California" was published. The letter from Nevada county, in another column of the issue, gives some interesting items in relation to the subject.

On the 18th inst. a body of oil yielding, according to report, 40 barrels a day, was struck in a well 400 feet deep in the San Fernando oil district, 17 miles northwest of the town of San Fernando and five miles from the Andrew station on the Southern Pacific railroad. Five other wells, all of them, including the new one, within an area of one acre, had previously reached a flowing supply of oil, but the quantity from the five was only 40 barrels in the aggregate, so that the new one equals in importance all the others together. The cause of its superiority is probably to be found in the fact that it goes down twice as far as the older wells, and is the first to reach so great a depth.

A VERY destructive fire occurred at Marblehead, Mass., on Monday. Nearly the entire business portion of the town was destroyed. Loss about \$500,000.

dinance prohibiting the discharge of cannon and fireworks, so as to include all kinds of fireworks in the prohibition, within city limits. An addition has been made to the order declaring it the duty of the Chief of Police and every member of the Department to enforce the ordinance.

The route of the procession will be as follows: Start from corner of Folsom and Third streets at 10 A. M.; thence to Market street, to Montgomery, to Montgomery Avenue, to Kearny, to Market, to Seventh, counter-march on Market to Powell, to Sutter, to Kearny, to Bush. At this point the procession will break up and those who desire to attend the literary exercises will go to the California theater. The Brigade review will come off before the procession forms, at 9.20 A. M., the line forming on New Montgomery street.

The engraving on this page gives a good view of a Fourth of July celebration by moonlight. It is an occasion of promenade, lemonade and fusillade. The populace is devoted to recreation and enjoyment. The figures show boys and girls handling the fiery cracker and spouting candles of Rome. Their elder brothers and sisters celebrate rather with the flash of sentiment and the warmth of sprouting affections. The old people wander about in aimless ways and will rejoice when the time comes to draw the unwilling children to their homes. The scene is one which will be reproduced all over the country on next Wednesday night.

Secure Your Patents.

Miners should not forget that it is necessary to procure a government patent to their mining claims before they can be sure of an undisputed right to the premises. They should also remember that the longer they delay their application for a patent, the greater is the probability that there will be trouble with adverse claimants.

Our country has a good reputation among Eastern capitalists, and during this and each succeeding year a large amount of money will be brought to San Juan for the purpose of being invested in mines and mining stocks. After becoming satisfied as to the value of a mine, the question with the capitalist is the title. If the patent has been secured, that settles it. If not, the chances are that the would-be purchaser will look elsewhere, or that he will not be willing to give anything like a fair price for the property in question.

If the miner does not desire to sell his property, it is far better to settle the question of title and be done with it. He is thereby relieved of all anxiety as to future possibilities, and will be relieved of the necessity of the regular annual expenditures in order to hold his claim. A miner may have expended ten thousand dollars in developing his claim, and yet should he fail for but for a single year to do a hundred dollars' worth of work on it, the claim is liable to be relocated as abandoned property, and certainly would be if it was worth anything.

If a mine is worth having, it is certainly worth paying for at the very low rate of \$5 per acre. We therefore urge upon miners the necessity of securing their patents at the earliest day possible.—*San Juan Mining Reporter.*

Hydraulic Engineering.

Manufactories are located with reference to convenience to fuel, raw material, power and transportation. Since the introduction of railroads and the discovery of coal, cheap transportation has taken the raw material and fuel to convenient points without reference to power, as coal furnishes both power and fuel. Since the application of steam, water power has not been considered as necessary for the location of manufactories. Nevertheless, the presence of water power is an additional reason for the location of manufactories, and water power is most economical and the power equally steady. Where natural waterfalls exist they have been largely taken advantage of in the Eastern States, and the raw material and the food for the operatives have both been transported there, and then the product transported back to the source whence the food and raw material came. As an instance of what has been done to occupy the power thus afforded, the dam across the Connecticut river at Holyoke, Massachusetts, is said to have supplied that city with the enormous amount of 300,000 horse power. The water is taken by canal from the river along the highest practicable terrace, and there used through mills on the lower side of the canal, emptying into a canal on a terrace below, when it is again used, and again emptying into other canals upon other terraces further below. Where a few years since was but pasture lands, is now a large and rapidly growing city.

SWANSEA REDUCTION WORKS.—We find in an exchange a description of the celebrated reduction and separating works of Wales. We give space to a brief extract: "The Swansea works are mostly subterranean, extending for about a mile underground, the compartments each separated from the other, and the man who has charge of any one apartment is completely walled out from his neighbors on both sides, so that no one knows what the other person next to him is doing. The employees live in such prisons all their lives, have no communication with each other, or the outside world, hence, if one quits, he knows nothing, except that he was required to use certain proportions of chemicals to extract a given metal, as the rivulet of molten matter passed through his chamber. This is the reason why no one can be found that knows the *modus operandi* of the entire Swansea works, from personal observation, for no one but the proprietors themselves understand it, and they will not impart the information for the simple reason that all the world pays tribute to them. Yes, the little Welsh corner by the sea has cargoes of mineral from every country on the globe unloaded at her wharves."

IRON CEMENT.—Take four or five parts by weight of dried and finely-powdered brick earth, and one part of peroxide of manganese, and mix them with two parts of fine iron filings, which must be free from rust, one-half part common salt and one-half part borax. Grind all fine together and mix intimately, then make into a stiff mass with water. The cement must be applied as soon as made; it is first gently warmed, and then exposed to a heat just short of whiteness. It is stated to be thus converted into a slag-like material which stands boiling water and all common heats. Another recipe is: Equal parts of finely-sifted peroxide of manganese and finely-triturated zinc, which are rubbed up to a thickish fluid with common water glass; this must be applied as soon as ready, and makes as hard a cement as the foregoing.

Summerville.

A reporter of the *Sunshine* (Col.) *Courier* visited this prosperous camp last week, and found things far beyond his expectations. New and commodious dwelling houses are being erected, and many people are compelled to live in tents on account of the scarcity of houses. There are already thirty dwelling houses erected and occupied.

This is the location selected by the Black Cloud mining company for their mill, which is now being erected, and twelve carpenters are as busy as they can be at work, with but seventeen days to complete their work. The building will be 102x39 feet, with five floors in the mill, and to be the same as Collom's works.

The Black Cloud mine, owned by the same company, is located up the gulch from the mill, with a dump of ore that is estimated at 1,000 tons; however, there is enough ore to prevent men from doing any more work until the ore is removed to give them a chance to work. The company will have the mill and mine in full operation about the first of August.

There are several other mines in the immediate neighborhood of Summerville that will commence work at once; among the number we mention the famous Hoosier.

BARTHOLOMI'S COLOSSAL "LIBERTY."—In an article entitled "France to America," in *Scribner* for June, occurs the following description of Bartholdi's colossal "Liberty," which is to stand in the harbor of New York: Allowing twenty feet for the height of the island above the water, the pedestal is to be one hundred and ten feet high, and the statue, to the flame of the torch, one hundred and forty-five. This makes the torch at least two hundred and seventy-five feet above the level of the bay. It will equal in height the column in the Place Vendôme at Paris, and will be larger than the colossus of Rhodes, so much celebrated by antiquity. Like that statue, it will have to be cast in pieces of manageable size, and built up after the manner of an armored frigate. The construction will be a curious specimen of engineering skill, for which the sculptor and Mr. de Stuckle will be responsible. At night it is proposed that a halo of jets of light shall radiate from the temples of the enormous goddess, and perhaps the flame of the torch may be fashioned in crystal, in order that it may catch the light of the sun by day, and at night form a glowing object illuminated by electricity.

Steam Engines & Boilers.

NEW AND SECOND-HAND.

- One Patent Straw-Burning, Portable Engine, (new,) fire box boiler, the best Portable Engine on the coast; built by Ransom, Sims & Head, Ipswich, England.
- One Steam Fire Engine, second-hand, in excellent condition, with 200 feet leather hose, very cheap, just the thing for a small town. Button & Blake, builders, Waterford, N. Y.
- One second-hand Stationary Engine, 14x30 inches, link motion, with or without hoist gear.
- One second-hand Stationary Engine, 8x20 inch, with or without hoist gear.
- One Upright Boiler, Horizontal Engine on wheels, Eastern make, 7x12.
- One Upright Boiler, Horizontal Engine, San Francisco make, 6x12.
- One small Stationary Engine, 3½x7 inch.
- One Steam Boiler, 40 inches diameter, 16 feet long.
- One 8x10 Straw-Burning Portable Engine.
- One Traction Engine, three wheels, rubber tires, double cylinder, 6x10 inch; Thompson's patent, D. D. Williamson, builder, New Jersey.
- One Stationary Engine, 10x20, just had a thorough repair, almost as good as new.
- One Stationary Engine, new, 12x24, independent cut-off.
- One 6x12 Engine and Boiler, can be mounted if required. Very cheap.
- Various other second-hand Engines and Boilers for sale cheap.

DEWEY & CO.

American & Foreign Patent Agents

OFFICE, 224 SANSOME STREET, S. F.

PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.

Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

ARITHMETIC MADE EASY.

ROPP'S
EASY CALCULATOR

Is a new publication that must prove of incalculable
 benefit to Farmers, Mechanics and Business Men. It is
 so rapid and original as to startle the most scholarly,
 and yet so simple and practical that the most illiterate
 in figures can instantaneously become his own account-
 ant. It enables thousands to accomplish in a minute
 what they could not learn to calculate in many months.

The first part contains an entirely new system of tables,
 which show at a glance the exact value of all kinds of
 Grain, Stock, Hay, Coal, Lumber, Merchandise, etc.,
 from one pound up to a car load, and for any price that
 the market is likely to reach; the interest on any sum for
 any time at 6, 7, 8 and 10 per cent.; correct measurement
 of all kinds of Lumber, Saw Logs, Cisterns, Tanks, Gran-
 aries, Bins, Wagon Beds, Corn Cribbs; a Time, Wages
 and many other valuable tables.

The second part is a practical arithmetic, and embodies
 a simple mechanical principle which enables any one
 familiar with the fundamental rules to become a light-
 ning calculator, and by which over two-thirds of the fig-
 ures and labor required by the ordinary methods, and
 fractions with their intricacies, are entirely avoided.

The work is nicely printed on fine tinted paper, is well
 and elegantly bound in pocket-book shape and is accom-
 panied by a Silicate Slate, Memorandum and Pocket for
 papers. It is by far the most complete, comprehensive
 and convenient pocket manual ever published.

Price, bound in Fine English Cloth, \$1.00.

Sent direct from the Eastern publisher, postpaid, on
 receipt of price, by P. O. order, registered letter, or
 receipted by express. Address

TULLOCH'S AUTOMATIC ORE FEEDER,

Awarded the Centennial Medal.

The TULLOCH AUTOMATIC ORE FEEDERS have been practically tested during the last year and a half in
 40 mills, of from five to 80 stamps each, and have, in every case, given perfect satisfaction. The Tulloch machine is
 so constructed that the drop of the stamp feeds the ore in just such quantities as the stamps require. Each drop
 regulates the supply required for the next drop, whether it be more or less, and this is the true principle of an
 automatic feeder. The tray moves longitudinally, and a stationary scraper forces the material forward at each back-
 ward movement of the tray, thus insuring the perfect feeding of all classes of ore, whether it be dry or wet.

We append a few extracts from the many testimonials which we have received from mill men and practical
 mining men, of the effectiveness and positive action of the Tulloch Feeder. We do not depend solely upon these
 testimonials, as we are aware that testimonials are easily secured for almost any machine, but the high character of
 the parties certifying to those herewith given, will establish their value and genuineness:

Mr. Jas. G. Fair has 28 in use; says: I regard them superior to any Feeder with which I am acquainted; I con-
 sider no mill perfect without them. Mr. E. R. Burke, Sunner mine, Kern county, has 18: They never get tired; no
 man living can feed a battery as well; they save us in labor alone \$48 a day. Mr. Green, of the Phoenix mill (12),
 Amador, writes: The first machine we had is working away; is as good as ever; have not spent a dime on it; in use
 14 months; you need fear no competition on wet ores. Mr. W. H. Armstrong, of Consolidated Virginia mill: We are
 running 60 stamps with your Feeders; they give unbounded satisfaction; they have not cost the company one dollar
 since starting up. Mr. H. C. Bidwell, Supt. Green Mountain and Gold Stripe companies, Plumas county, writes:
 From the start they have done splendidly; no trouble whatever; requiring but little attention; a boy can manage
 them; the saving in both labor and castings is fully one-half over the old style of feeding by hand. Mr. Preston
 writes: I have four of your Automatic Self Feeders, and my mill men each and all say they are the best they have
 ever used. They are an improvement on all I have ever seen, being simple in construction, and good for either wet
 or dry crushing; refer to over 40 mills using them; they are guaranteed to give perfect satisfaction. Send for circulars.

Mining in the Upper Part of Nevada Co.

(From Our Traveling Correspondent.)

Pre-science is the best mark of a true scientific theory. When results are predicted from it with any degree of certainty and in instances sufficiently numerous to preclude the idea of chance or coincidence, the hypothesis begins at once to take the form of an established law. In view of the value and vastness of the rich auriferous gravel deposits found in this locality in connection with the thousands of broad acres all along the western slope of the Sierras from Oregon on the north as far south at least as Fresno county, many an attempt has been made to arrive at the causes that evidently at one time operated here on a scale by no means diminutive, and to solve or more definitely settle the question as to the age and mode of the deposit. The ultimate and most important end to be attained has been the discovery of some law by which locations could be made and at the same time opened, not at mere hap-hazard, but with something of that degree of certainty and success invariably accompanying Dame Nature's footsteps when carefully traced out and faithfully followed. Some of these efforts have not been entirely unproductive, and richer harvests may yet be expected. Without going into the facts, the different views may be briefly summed up about as follows:

1st. There is the oceanic hypothesis, from the belief of its few advocates that the gravel was an ocean deposit similar to the rich sandbanks of Gold Bluff and other points on our northern coast.

2d. The glacial, held by certain scientists of repute, who claim the effects to have been produced in some mysterious way by the action of ice, either in the form of some floating Lapland iceberg or slower moving Swiss glacier; and, to do the assumption justice, accounts well for some of the later facts, and so far not conflicting with the 3d and most generally received view, known as the

Old River Channel Hypothesis.

This has been found to so fully answer to all the facts in the case, and has so far fulfilled the predictive characteristics expected from a well-grounded theory, as to be fast assuming both the form and dignity of a well determined law. But few of our most intelligent, practical miners now question its correctness. Some of the closest observers and acutest thinkers in other pursuits and professions have come to a like conclusion.

Claims have been located and tunnels run on the strength of the belief, resulting in a further verification and stronger conviction of its truth. The case of the Hidden Treasure in Placer county, referred to in our last year's correspondence, is a striking instance in point. All the calculations for running the tunnel were based on the ascertained course and grade of the channel as found at Damascus, fully five miles from the new location. As it turned out, the best possible selection was made both for reaching and working the gravel. As much as has been accomplished, the work may be said to have just begun.

Serious Difficulties

Are in the way, requiring time and patience to overcome. While the advocates of the underground river system are wholly in accord as to the forces originally employed, they are by no means agreed even as to the general direction of the main channel, to say nothing of minor differences. This is nothing more than might be expected at the present stage of the inquiry, more particularly in view of the obstacles that might naturally be anticipated on entering a great unexplored field of physical geography, such as is here presented for exploration.

It must be remembered that numerous and wonderful changes have taken place on the coast since the waters of what is known as the old Blue lead first began to treasure up these golden sands for the benefit of future ages. Imagine the elevations and depressions that have since taken place; the number of blazing volcanoes that have poured down their fiery streams, filling the channels to overflowing, causing them to run at higher or lower levels, or force a passage towards old ocean in a new and different direction, and these wearing away portions of the mother lead, to be in turn afterwards partially obliterated by the same or a similar process.

Differences of opinion have arisen in some cases also from a lack of opportunity for making proper observations and also from drawing conclusions from a limited number of facts or from indications as presented in special localities. For instance, an observer in Plumas county might come to the conclusion that the general flow of the main channel had been southerly; one in Yuba westerly, and another in Placer that it ran northerly into Oregon, each judging from his particular point of observation. Each might be in possession of the facts for his individual locality, yet his inference for the direction of the channel its entire length might not be correct. The whole of the observations, at the same time, might be in harmony, and dovetailed so well together as to go far towards the formation of a true theory. Without undertaking to say that the facts as at present arrived at are sufficient to fully justify such a view, it is not unreasonable to suppose

that one great branch came from the north and another from the south, making a junction, if you please, somewhere in Nevada county, and flowed thence westwardly. Such is substantially the ground taken in the year 1875 by Mr. C. J. Brown, Esq., your correspondent from Dutch Flat, who has given much attention to the question in general and to this point of the belt in particular. He has ventured so far into this "terra incognita" or dead river series as to draw.

A Provisional Map,

Showing the great western trunk, formed by the confluence of the two main northern and southern channels, together with the chief branches of each, going even into the minutia of locating some of their smaller tributaries. It is a step in the right direction and ought to be published for further confirmation, corrections and additions. This could be done with little labor and expense by the miners at work at the different points along the line of the belt, and the general questions, at least, could be soon settled, thereby greatly advancing the interests of science, and likely to lead to practical results, possibly valuable beyond all computation.

In this connection, room must be asked for one fact from personal observation, called to mind by the map and confirmatory of the view just presented.

At Damascus, alluded to above, the channel has been followed by a tunnel for more than a mile, where the old current gives every evidence of having set in a northerly direction, a matter readily determined by the grade on the bed-rock and by the relative position of boulders and gravel or other marks equally easy of interpretation by the practical eye of the miner.

Gravel and Drift Mining.

The operations in this portion of the county are on a grand scale. Millions have been invested in ditches and reservoirs. The outlays have been for the most part judicious, giving large returns for the capital employed, and, at the same time, supplying the needful sinews for opening and working the vast gravel deposits that everywhere abound.

From French Corral on the west as far north and east as Eureka South, including the vicinities of Sweetland, Cherokee, Columbia Hill, North Bloomfield, Moore's Flat and points intermediate, the channels are everywhere giving evidences of their richness by regular monthly shipments, or by the richer promise foreshadowed by the present developments.

As an able and exhaustive article appeared in your last issue, taken from the Nevada Transcript, in regard to the gravel mines of this ridge, much that had been written up is withheld as superfluous, and only a few claims noticed by way of illustration.

The Milton M. and W. Co.

Own a ditch right of 40 miles in length, taking water from the Middle Yuba. Their bedrock tunnel at French Corral is 3,500 feet long, with sluices discharging into the South Yuba. The mine is in full blast, the gravel represented to be very rich, and paying them handsomely.

The Manzanita at Sweetland, the property of same company, is also running at this time with a full force. Tunnel, 1,700 feet in length, and sufficiently deep to exhaust the gravel, with flume-way three-fourths of a mile long, dumping into the main Yuba. Their mines, inclusive of a claim at Birchville and another at Badger hill, are numbered among the best in the county.

The American M. Co.

Have 2,000 feet of ground at Sebastopol yet to be worked. The claim is situated 600 feet higher than the Middle Yuba, giving them admirable dumping facilities. They have four working tunnels, the main lower coming out of the hill 240 feet above the river. It is 3,920 in length and makes connection with a vertical shaft, 177 feet deep, in the bedrock. Below its mouth there are 20 under-currents and no less than 30 more above, connecting with the other tunnels, and from 40 to 80 feet in length by from 20 to 40 in width, with a grade of 15 inches to 14 feet; main flume, five feet wide; grade, 10½ inches to 14 feet.

The natural facilities as well as the mechanical appliances for saving the gold are excellent, the loss being estimated at less than 10%. The company are employing over 60 men, using 1,600 inches of water under an outlay of from \$10,000 to \$12,000 per month for running expenses, and are said to be making it pay.

The North Bloomfield M. Co.

Their ground at a place of the same name consists of 1,650 acres; length of channel, two miles; height of bank, 360 feet, the whole, except a streak of pipe clay, from 2 to 20 feet thick, containing gold in paying quantities, the depth of blue gravel being about 120 feet. The claim has been opened by a tunnel one and one-half miles in length, at a cost of \$500,000, their entire property at this point costing about \$1,500,000. The fall from the mouth of the tunnel to the South Yuba is 500 feet, giving room for all the dumps and undercurrents that may be required. The quantity of water used the present season varies from 2,500 to 3,000 inches, and realizes from 45 to 75 cents per inch for 24 hours, while the total expenses per month are not far from \$10,000; from all of which it will be seen that the capital has been well employed and is already beginning to pay a good per cent. on the investment.

The opportunity was here afforded of again witnessing the practical working of the new deflecting nozzle alluded to in a late letter from Plumas, and learning more of the principle of

its operation from Mr. H. C. Perkins, the Superintendent of the mine and the inventor of the machine. Being movable and working on a universal joint, it is operated by a lever, the water passing through the pipe being used as the power for moving the monitor, and it is truly wonderful to see with what ease one of these large monitors, throwing from 1,800 inches of water under a pressure of 375 feet, could be handled, the force exerted by the movement of a single finger being sufficient for the work. It was understood also that the new Judson powder had been tried here—9,000 pounds at a blast—doing fine execution and giving entire satisfaction.

Quartz in the upper part of the county is now attracting more than ordinary attention.

The Republic M. and M. Co.

Was incorporated but little more than one month ago, since which they have run over 100 feet of tunnels, and have a 20-stamp mill far on the way toward completion. The claim is situated two miles from Eureka South, on the old Henness pass road, and was worked to some extent many years ago. The company, before purchasing, sent 10 tons from different parts of the mine to Nevada City as a test, that yielded at the rate of \$9 per ton. One tunnel previously driven 200 feet, cutting in its course some small rich veins, and one four feet in width, had tapped the main ledge and passed into it 30 feet or more, which is known to be fully 53 feet wide. Another had followed along the foot wall 135 feet, and was expected to make connection with the cross tunnel early in July, or by the time the mill would be in readiness for crushing.

For driving power, a head of water of 120 feet is supplied at very low rates from the Bloomfield ditch. The quartz, mixed somewhat with talcose slate, is estimated to run from \$5 to \$10, the gold being pretty evenly distributed. It will not be difficult to mine or deliver at the mill, and there is every reason to believe that it may be made to pay well. The cost of mining and milling ought not to exceed \$3 per ton.

The Bulldoser,

A little above Graniteville, or Eureka South, is owned by Messrs. Rooker & Fairweather. Work was commenced in March by sinking a shaft. It has since been laid open at different points for 750 feet, averages a width of three feet, and is in a granite formation. Tests made of the quartz by arasta show a value of \$12 per ton, taking no account of the sulphurets of iron and lead with which it is highly charged. It has all the advantages of free water, timber in abundance, and plenty of fall for mill and machinery. It was being vigorously worked.

The Rocky Glen,

From one to two miles south of Graniteville, and at this time the property of Mr. J. Hibbert, has an average width of six feet, the whole of the quartz being extracted and worked. It carries a considerable quantity of free gold with sufficient sulphurets for one pan, and pays from \$6 to \$15 per ton. The mine under the present management has yielded in the gross for the two past years about \$14,000, more than paying all expenses for developing and improvements. The rock from the upper level is here conveyed to the mill by water through a small flume lined with blocks for the double purpose of protecting its bottom and saving the free gold contained in the mud and sand. A similar method might be adopted to advantage wherever water is at hand, as 40 tons can be delivered at the mill by two men in 10 hours, at a saving over hauling of more than \$1 per ton, and at the same time furnishing the rock to the stamps free from all mud and sand.

The Centennial,

Six miles south, averages two and one-half feet, the quartz assaying from \$200 to \$300 in gold and silver and the sulphurets as high as \$1,240 per ton of same. A small lot tested by Mr. S. McCurdy at the Canyon Creek mill, worked up to \$168 in gold. Such is the confidence of the company in the value and quantity of the ore already extracted and in sight, that they have engaged the machinery for the mill, which is expected to be in running order by the 1st of August.

The Yuba gold mining company, Mr. Geo. Lord, Superintendent, have done a large amount of work six miles above Washington, where they have located half a dozen parallel ledges near the South Yuba.

The country rock is a species of granitic syenite and the vein on which the greater part of the labor has been performed is found to vary from three to five feet in thickness. Four different tunnels have followed along the lode, the lowest entering 30 feet above the river and running a southerly direction into the mountain, reaching a depth from surface of 450 feet or a point 2,300 feet lower than the summit.

A second level has been driven 200 feet above; a third, 1,000 feet higher and a fourth, full 400 feet above the last, so that the mine is pretty thoroughly prospected and in a condition to furnish ore with dispatch and in quantity.

The rock from wall to wall is represented to work from \$6 to \$30 per ton. The company have a 25-stamp mill, driven by an overshot wheel, 36 feet in diameter, with a 6 foot breast, and possesses enviable advantages in the way of water power.

They are vigorously driving every department of the business, giving employment at present to nearly 50 men. The aspect of affairs, taken all in all, presents an air of thrift and prosperity not often found in the older mining districts

and the highest hopes for its future are entertained.

As the mountain here rises at an angle of 45°, the quartz glides down to the mill from the upper tunnel simply by force of its own gravity.

The chute is 2,000 feet in length, made of lumber and bottom lined with iron.

A mile above is

The Yuba Canyon Mine,

The property of Messrs. McCurdy Ogden & Co., showing a lode from three to five feet in width. It is thought that the rock will work as much as \$30 per ton just as it comes from the mine, selected specimens yielding by hand mortar as high as \$1,000.

Favorable accounts were received of the Lindsay, Harris, Piper, Erie, California and others on the same belt, so that the outlook for Graniteville and Washington may be looked upon as better than it has been for years.

A. C. K.

Suspension Bridge in Mendocino County.

Mr. R. W. Gorrill, Treasurer and Engineer of the Pacific Bridge Co., gives us the following particulars of a new steel wire suspension bridge which he is erecting in Mendocino county for Mr. W. R. Miller. It is located at Cottonova, on the coast, and extends from the main land to a rocky island where a chute is to be built for shipping lumber.

The distance from center to center of the saddles on the towers is 270 feet. The deflection or fall of the cable is 23 feet, six inches. The cables are built in the same manner as those of the Clifton bridge, at Niagara. The steel wire is about No. 11 Birmingham gauge, and is protected against rust by immersing in a bath which gives it a fine coat of zinc. There are 11 wires in each strand, seven strands in each one and one-half inch rope, and seven ropes in each cable. The ropes are not twisted together to form the cables, but gathered up every six feet by the suspender bands. Each rope is warranted to bear a strain of 60 tons. Each rope is made fast to an independent anchor-bar, one by three inches in diameter, and forming links 18 feet long, until connection is made with the anchors. The anchors are of cast iron, three and one-half by three feet in surface, weigh 1,000 pounds each, and are placed 14 feet below the surface of the rock.

Great care was taken in securing these anchors in place by means of cross I beams which run under the rock on either side. The lower part of each pit was enlarged so as to form a hemispherical chamber, and the rock-work, set in Portland cement, which is built upon the anchor, is so constructed that the upward strain is transmitted to its sides. The towers are of redwood. There are four posts 10x10 inches, and two 10x12 inches, giving an effective area of 640 square inches to withstand the strain of the cable on the tower. The wooden truss to prevent vertical vibration is eight feet high and of the Howe truss pattern. The 270 feet of the bridge is divided into 45 panels. The longest suspenders, 44 in number, are of seven-eighth-inch steel wire, the 42 shorter ones are of one and one-eighth-inch solid iron.

The estimated dead load of the bridge is 1,000 pounds per linear foot; live load, one ton per linear foot; in all, one and one-half tons, or one-fifth of actual breaking load. The bridge will be completed in about 30 days, and promises to be a structure which the builders may well be proud of.

We were shown a portion of an iron bar from the Ashtabula bridge, which was so crystalline in its structure that probably not one-twentieth of its substance had any greater strength than pig iron. This unfavorable condition was undoubtedly produced by the rearrangement of the molecules, produced by the vibrations of the bridge under passing trains and changes of temperature. Mr. Gorrill prefers a combination of wood and iron in the truss bridges, as the elasticity of the former saves the iron from the severe strain which is put upon it when all parts are rigid. He also insists upon a factor of safety of five in ordinary bridges and six for railways. We hope to illustrate this subject with a good cut of the bridge and some of its more important details before long.

Items of Interest from the Mines.

We give below items of interest from prominent mines, most of which are collated from letters of the respective Superintendents on file at the offices in this city:

The Condor mill at Pioche was burned on the 22d inst. The mill was leased by the Alps company and the lease had one month to run.

The various ore bodies in the Eureka Con. all show decided improvement in extent and quality. The furnace continues to turn out 13 tons of bullion per day.

They are taking out 50 tons of ore a day from the Belcher.

They now have good air in all parts of the El Dorado South.

A valuable strike has been made in the Look-out ground of the Modoc Con. mine. The ore gives promise of a large body and assays \$229.34.

Car samples of Chollar ore assay \$23.50 per ton.

The ore breasts in the Con. Virginia 1650-foot level continue to look finely.

The several ore stopes on the various levels of the California mine look well.

Sansome Street.

DEWEY & CO.'S PATENT OFFICES, MINING AND SCIENTIFIC PRESS AND PACIFIC RURAL PRESS newspaper offices, and the SCIENTIFIC PRESS ENGRAVING establishment will be found at the above place, (No. 202 Sansome Street, N. E. Corner of Pine, opposite the Pacific Bank), after July 4th, 1877. Just three-fourths of a block south of our old location.

PATENTS AND INVENTIONS.

A Weekly List of U. S. Patents Issued to Pacific Coast Inventors.

[FROM OFFICIAL REPORTS FOR THE MINING AND SCIENTIFIC PRESS, DEWEY & CO., PUBLISHERS AND U. S. AND FOREIGN PATENT AGENTS.]

WEEK ENDING JUNE 10TH, 1877.

192,062.	HYDRANT.—W. T. Garratt, S. F.
192,063.	SPARK ARRESTER.—J. Gates, Portland, Ogn.
192,069.	SAW TERTH.—N. W. Spaulding, S. F.
192,090.	SAW TERTH.—N. W. Spaulding, S. F.
192,121.	FANERINO DEVICE FOR MAIL BAGS.—J. Metz and E. Himmann, Denver, Colo.
192,140.	COMPOUND FOR THE MANUFACTURE OF PORCELAIN FOR DENTAL PLATES, TERTH, ETC.—A. B. Cady, Ronton, Ogn.
192,162.	FOUNTAIN.—W. J. and W. H. Clark, Salem, Ogn.
192,165.	COMPOUND STEAM BOILER.—R. R. Hind, Hobaia, Hawaii, Hawaiian Islands.
192,182.	DEMOLITION CASE.—C. Newman, S. F.
192,191.	ORE SEPARATOR.—J. Richards, Battle Mountain, Nev.
192,314.	CAR-PROPELLER.—M. A. Wheaton, S. F.

General News Items.

ROBERT DALE OWEN died at Lake George on Sunday last.

NEARLY all the silk weavers at Paterson, N. J., are out on a strike.

THE Turks and Russians are having some very lively fighting on the Danube.

THE Chico soap factory has been burned again. The incendiaries have not been caught.

FOURTEEN "Mollie Maguires" were hung on Thursday of last week in Pennsylvania.

THE Lick monument is to be set up at once in the cemetery at Fredericksburg, Lebanon county, Pa. It contains seven large statues, and cost \$20,000.

THE court of inquiry into the loss of the steamship *City of San Francisco* has rendered a decision depriving Captain Waddell of his certificate as Master for a period of 12 months.

A DISPATCH from Omaha says that Sidney Dillon and Jay Gould have returned from the West. It is said on good authority that the road to the Black hills will not be commenced this year.

UNDER the apportionment by the Commissioner of the General Land Office of the gross sum of \$300,000 appropriated by Congress for land surveys during the next fiscal year, for the survey of private land claims, New Mexico gets \$35,000; Colorado, \$2,000; California, \$6,000; Arizona, \$5,000. For the survey of public lands, Colorado gets \$35,000; Utah, \$16,000; Nevada the same; Washington the same; Arizona, \$8,850.

NOVELTY IRON WORKS.—These works, which are situated at 215 and 217 Front street, in this city, have come under a new management. Mr. G. L. Pierce, mechanical and hydraulic engineer, is the new proprietor. Mr. Pierce was one year engineer at the Mechanics' Institute fair. He has for some time been engaged in hydraulic engineering enterprises, and was the person who put up the large pumping apparatus at Grand island. He is now prepared to do general work of all kinds at the Novelty Works, being well provided with necessary tools, etc.

New Incorporations.

The following companies have filed certificates of incorporation in the County Clerk's office at San Francisco:

BLUE BIRD M. & Co.—June 21. Location: Arizona. Capital stock, \$100,000. Directors—W. H. Knight, Jos. Daly, E. Bannison, West Evans and Andrew Luckey. FRESNO G. M. Co.—June 25. Location: Fresno Co. Capital stock, \$5,000,000. Directors—Wm. De Fresco, C. W. Tozer, D. M. Sinton, Geo. P. Terry and Daniel Buck. MONARCH GRAVEL M. Co.—June 22. Location: Calaveras county. Capital stock, \$1,000,000. Directors—A. G. Bradbury, H. P. Wakelee, J. M. Streeten, G. H. Bradbury and Robert Barron. CALIFORNIA ELECTRICAL WORKS.—June 25. Capital stock, \$600,000. Object: to engage in and carry on the business of manufacturing and dealing in telegraphic and electrical machinery, apparatus, etc. Directors—George S. Ladd, Dr. Cornelius Herz, James Gamble, Russell J. Wilson and James E. Boyd. The officers of the company are George S. Ladd, President; Dr. Cornelius Herz, Vice-President; Joseph Herz, General Manager.

WOODWARD'S GARDENS has the following new attractions: The buffalo cage; large whale skeleton; new museum; improvements in the zoological department, besides the other features which have made it popular.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Bella Union Quicksilver Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Napa County, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the twenty-eighth day of June, 1877, an assessment, (No. 2), of ten cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary at the office of the company, No. 312 Montgomery Street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the thirtieth day of July, 1877, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Saturday, the twenty-fifth day of August, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors, ABRAHAM HALSEY, Sec'y.

Office, No. 312 Montgomery Street, San Francisco, Cal.

Booth Gold Mining Company.—Location of works, Auburn, Placer County, California.

Notice.—There are delinquent upon the following described stock, on account of assessment, No. 2, levied on the thirtieth day of April, 1877, the several amounts set opposite the names of the respective shareholders:

And in accordance with law and an order of the Board of Trustees, made on the thirtieth day of April, 1877, so many shares of each parcel of said stock as may be necessary, will be sold at public auction, at the salesroom of J. Middleton & Son, No. 310 Montgomery Street, San Francisco, Cal., on the twenty-fifth day of June, 1877, at the hour of two o'clock, P. M., of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

GEO. R. SPINNEY, Sec'y.

Office, No. 320 California Street, Room No. 5, San Francisco, Cal.

Consolidated Bonanza Gold and Silver Mining Co.—Location of principal place of business, San Francisco, California. Location of works in Eagle and Washoe Valley Mining District, Ormsby county, Nevada.

Notice is hereby given, that at a meeting of the Board of

Trustees, held on the fourth day of June, 1877, an assessment, No. 1, of 10 cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. gold coin, to the Secretary at the office of the company, No. 19 First Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on Tuesday, the tenth day of July, 1877, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the thirty-first day of July, 1877, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Trustees, WM. MARTIN, Secretary.

Office No. 19 First Street, San Francisco, Cal.

Empire Mining Company.—Location of principal place of business, San Francisco, California.

Location of works, Silver City, Owyhee County, Idaho Territory.

Notice.—There are delinquent upon the following described stock, on account of assessment, No. 13, levied on the 26th day of April, 1877, the several amounts set opposite the names of the respective shareholders, as follows:

Iron and Machine Works.

PACIFIC ROLLING MILL COMPANY,

SAN FRANCISCO, CAL.

Established for the Manufacture of

RAILROAD AND OTHER IRON

Every Variety of Shafting,

Embracing ALL SIZES of

Steamboat Shafts, Cranks, Piston and Connecting Rods, Car and Locomotive Axles and Frames,

Hammered Iron of Every Description and Size.

Orders addressed to PACIFIC ROLLING MILL COMPANY, P. O. Box 2032, San Francisco, Cal., will receive prompt attention. Office: 16 First Street.

The highest price paid for Scrap Iron.

THE RISDON

Iron and Locomotive Works,

INCORPORATED.....APRIL 30, 1868
CAPITAL.....\$1,000,000.

LOCATION OF WORKS:

Corner of Beale and Howard Streets,

SAN FRANCISCO.

Manufacturers of Steam Engines, Quartz and Flour Mill Machinery, Steam Boilers (Marine, Locomotive and Stationary), Marine Engines (High and Low Pressure). All kinds of light and heavy Castings at lowest prices. Cams and Tappets, with chilled faces, guaranteed 40 per cent. more durable than ordinary iron.

Directors:

Joseph Moore, Jesse Holladay, C. E. McLane,
Wm. Norris, Wm. H. Taylor, J. B. Haggin,
James D. Walker.

WM. H. TAYLOR.....President

Machinery and Castings of all kinds.

McAFEE, SPIERS & CO.,

BOILER MAKERS AND

GENERAL MACHINISTS,

Howard between Fremont and Beale Sts., San Francisco

San Francisco Pioneer Screen Works,

J. W. QUICK, MANUFACTURER,

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOTTED and SLOTTED PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates. Orders solicited and promptly attended to.

32 Fremont Street, San Francisco.

Machinery.

The Ingersoll Rock Drill

Is Extensively Used in the East and

TAKES THE PLACE OF ALL OTHERS,

Wherever introduced, because it can be run with less power, labor and repairs, and do more work than any other Drill in the market. It has but few parts, is easily handled, being light, and has AUTOMATIC FEED, which saves labor. WE ASK FOR TRIAL AGAINST ANY COMPETITOR. For particular information regarding Drills or Air Compressors, send for circular to

J. B. REYNOLDS,

(Room 10.)

320 Sansome Street

THE O'HARRA

CHLORIDIZING FURNACE

Guaranteed to Chloridize from 85 to 95 per cent. of any gold or silver ores that are not more profitable for smelting. Will also desulphurize ores and put them in proper shape for working in cupola furnaces.

Cost of Roasting and Chloridizing 20 Tons in 24 Hours by this Process:

One man.....	\$ 4 00
One man.....	3 00
Wood—2½ Cords at \$3 per cord.....	5 25
Salt—1,000 lbs at 2½ cents.....	40 00

Cost of 20 tons.....\$52 25
Cost of one ton.....2 61½

In a furnace of three or four times this capacity the cost is decreased by 20 per cent.

The furnace is now working successfully at the Poe Consolidated Co.'s mines, in Peavine District, Nev., and at the Exchequer mill, Alpine Co., Cal. For further information, apply to

D. J. O'HARRA,

Reno, Nevada.

Cor. Market & Fremont Sts., S. F.

THE VICTOR ROCK DRILL.

This machine is so simple in its construction that any person can understand and run it. The DOUBLE GOUGE BIT, patented with this Drill only, is one of its specialties, as it feeds and cleans itself. The machine is a hand Drill and can be operated by two men, who will do the work of ten in the ordinary way. In a word, it is a labor-saving machine which has no parallel, and as such we offer it to the public. For State or Territorial rights, or machines, apply to

MacDOWELL, KINZER & CO.,

216 Sansome street San Francisco Cal.

HUNT, DOUGLAS & STEWART Process,

Used in Connection With PURVINE

Wooden Amalgamating Pans and Settler.

This is a complete, perfect and economical adaptation of the humid method to the treatment of Gold or Silver ores, associated with

COPPER

And other base metals, or to ores free from base metals. It can be adapted to any first-class Gold or Silver mill, at a reasonable additional expense.

For further information, address

CAST STEEL SHOES
AND DIES.

Guaranteed Cheaper than the Best Iron.

IMPORTANT NOTICE.

Reduction in Price from 16 Cents
to 12 Cents Per Pound.

Owing to our largely increased business, the present low price of Iron from which our Steel is manufactured, and the improved facilities for casting and forging, we take great pleasure in announcing that from and after this date we will supply our IMPROVED CAST AND FORGED STEEL SHOES AND DIES FOR QUARTZ MILLS at twelve cents per pound, delivered at San Francisco or Sacramento, instead of sixteen cents, as heretofore.

We also furnish Steel Plates for Blake and other Ore Crushers, Steel Gut Gearing, etc., for Mills and Hoisting Works, Steel Pan Shoes, Battery Cams and Tappets, etc., etc.

Address all orders, with dimensions or drawings, to

Mining and Scientific Press

Is the leading mining journal in America, and enjoys a large circulation among the more intelligent operators and workers in the gold fields of the world.

As a scientific and mechanical representative of the Pacific Coast, it is decidedly popular and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special sphere unrivaled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer will find profit by its reading.

Subscription, \$4 a year in advance. Sample copies, post paid, 10 cents.

DEWEY & CO., Publishers, S. F.
